PUBLISHED MONTHLY AT

11 Wall Street, New York City.

TERMS OF SUBSCRIPTION.

United States and Canada, per annum,	$3.00
Four or more Copies, in Clubs (each) "	2.50
Great Britain and other Foreign Countries within the Postal Union "	4.00
Single Copies,	.30

[*Entered as second class matter at the New York, N. Y., Post Office, April 9, 1888.*]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. VIII. NEW YORK, JANUARY, 1889. No. 85.

SOME COMMERCIAL ASPECTS OF THE ELECTRIC LIGHTING BUSINESS.

ACCORDING to the figures given in the address of President Duncan, at the National Electric Light Convention in this city last summer, which subsequent investigations have convinced us were not overstated, there were then in use in the United States nearly 200,000 arc lights and nearly 2,000,000 incandescent lights, while the total horse-power of the engines employed in producing the electric current for operating them was in round numbers no less than 460,000. Taking into consideration the increase since that time, there can be no doubt that up to the end of the year 1888, a sum not less than $100,000,000 in cash or its equivalent has been expended by local illuminating companies and private consumers for the equipment and installation of electric lighting plants. No small share of this money has passed into the hands of four or five of the principal electric lighting companies doing business in the United States; but it is nevertheless an open secret that the instances in which the stockholders of these companies have received any substantial return for their investment have up to the present time been few and far between. It is a fact, patent to all, that a great share of the money has been absorbed by inventors, promoters, salesmen, lawyers, experts and sinecurists, great and small, too numerous to mention.

We have hitherto remarked on two or three occasions that indications are not wanting that this state of affairs is approaching its end. The law of the survival of the fittest is bound to assert itself sooner or later among electric lighting companies just as certainly as it has among railway, telegraph and other enterprises. It is the inevitable experience that the great companies get control of the smaller ones, and the profitable ones absorb the unprofitable ones. This result comes about from the operation of a commercial law, the processes of which can neither be retarded nor hastened to any considerable degree by the manipulations of individuals or of cliques.

We have been led to express these opinions by the occasional appearance of more or less detailed assertions in respect to consolidation alleged to be impending between the Edison Electric Light Company and the Westinghouse Electric Company. While it may be set down as certain that there is no truth in the rumors in the form in which they have reached the public, yet the progress of events makes it perfectly clear that, sometime in the future, commercial considerations must compel a certain harmonizing of conflicting interests between three or four of the most important electric lighting companies, which, as things are now going on, will soon be the only ones left in the field.

We venture to make this prediction, for the reason that the leading companies are coming more and more under the control of hard-headed business men, who well understand that it is for their interest to do business; to make money instead of to waste it, as has too often been the way in the past. Moreover, those who are thoroughly familiar with the general situation understand perfectly well that while the existing condition of affairs renders it futile for any one company to hope to control the electric lighting business to the exclusion of competitors by means of its patents, the combination of a few patents, which might be selected from among those owned by different and in many cases, hostile interests, if wielded by a compact and powerful executive, would not only control the business situation, but would render it possible for much better service to be given the public, and at a far greater profit to the stockholders than is now possible. Hence, nothing can be more certain than that the necessities of the situation will operate more and more powerfully as time goes on to bring about, if not union, at least harmony of interests in the direction we have indicated for the benefit of all.

DOGMATIC.

NOBODY is surprised, as a rule, at the chorus of ki-yies which is wont to arise from the kennel when a strange dog unexpectedly drops in and carries off a particularly large and delicious bone. Good old Dr. Isaac Watts philosophically bids us

> "Let dogs delight to bark and bite,
> For 'tis their nature to."

But we cannot restrain some expression of regret when we find our hitherto esteemed contemporary, the *Electrical Review*, of London, so far losing its temper as to indulge in ill-natured and currish remarks, such as we find in its issue of November 23d, in reference to the award of the contract for equipping the Sardinia street central station in London, to an American concern. It says:—

Now why is it that American contractors can beat us on our own ground? We can scarcely believe it to be on the score of price, and we fail to see how it is on the ground of extra efficiency. * * * * It is not as if we would not or could not do the thing decently.

Our contemporary then proceeds to answer its own question by inferentially imputing to the directors of the Metropolitan Electric Supply Company bad faith in respect to the opening of the tenders, and, still worse, makes what can only fitly be characterized as a scurrilous and unjustifiable attack upon the professional reputation of one of the consulting engineers of the Metropolitan company, whom it is impossible not to identify, even at this distance, as Professor George Forbes. It then adds as a sort of clincher:—

Moreover the directors (of the Metropolitan Electric Supply Company, Limited) Messrs. Pender, Anderson & Co., cannot well pose as patriots.

Quite so, esteemed contemporary! Your last shot was a bull's-eye. Messrs. Pender, Anderson, Elliott & Co., so far from being patriots, can pretend to be nothing more than mere trustees of a limited company ostensibly established for no higher purpose than that of making money. To this base and ignoble end they propose to convert coal into electricity, and sell it at a profit to the public (who, alas! are only too anxious to buy), and to distribute the net proceeds of this nefarious operation among the stockholders. Why, indeed, should these guinea-jinglers seek to pose as patriots?

No, the only thing apparently desired by them was to get their works in operation and earning money at the earliest possible moment, and so, in the most unpatriotic manner, they awarded the contract to parties who showed themselves best prepared to complete it promptly; who had executed in a satisfactory manner a vast amount of precisely similar work, and who were ready to guarantee to put down, and have in operation at a given time, a plant which should be capable of earning dividends from the day the steam should be turned on. We have plenty of such plants in the United States; but any one familiar with the endless catalogue of mistakes, failures and disasters which make up the history of central station electric lighting in England, knows but too well that a commercially successful central station plant will be a most refreshing novelty in that country.

In any event, it appears that half-a-dozen central station installations, more or less, are now in process of being set up in London, to say nothing of the colossal enterprise at Deptford, of which we gave some account in our last issue. If any or all of these turn out to be better or cheaper than the American-built station, or capable of earning more money, then will the matter—though not the manner—of our contemporary's remarks be justified. For its unmanly assault upon Professor Forbes, whose only misdeeds appear to have been the sale of his rights in the United States to a patented meter, and his subsequent recommendation, which as an unprejudiced counsellor he was bound, when called upon, to make, of the Westinghouse system as the one which had given the best financial results in the United States, why not, with equal justice and good taste, attack Sir William Thomson for getting his own syphon recorder into use on the Atlantic cables, or Mr. Preece for introducing his own railway signals on the South Western line? We should say that when it is proven that the recommendations of Professor Forbes were immediately beneficial to himself, or prejudicial to the interests of the corporation he was called on to advise, it will be time enough to berate him in the extraordinary language which our contemporary has seen fit to employ.

THE SUBWAYS.

The Board of Electrical Control of New York, is sharply attacked by the *Evening Post* in its issues of December 31 and January 2, a considerable portion of both its news and editorial columns containing criticisms of the commission and its work. The burden of complaint is that permits are still given for the erection of overhead wires, and that there are more overhead wires in the city now than when the Subway Commission was created for the purpose of causing all electric conductors to be put underground. An investigation by the Legislature of the acts and omissions of the board is recommended.

By all means let us have an investigation. If made thoroughly, and with the assistance of disinterested electrical engineers in the technical part of the inquiry, it would no doubt clearly reveal the causes of the unsatisfactory outcome of the three years' work of the Subway Commission, or Board of Electrical Control, as it is now entitled. These causes, in our opinion, are two;—first, the inherent difficulty of the work proposed;—second, the absurdly inadequate, not to say ridiculous, composition of the board appointed to plan and execute it. On these points the Electrical Engineer has several times expressed its views. Taken together they fully account for the situation. A board of competent men, totally unconnected with politics and unskilled in "deals," might not, perhaps, have put more wires underground, but would have brought the city much nearer a solution of the electric wire problem than it is at present. They would have made a more intelligent study of the undertaking before them, realizing that nothing like putting the entire electric service of a great city underground had been anywhere accomplished; and would not have placed the construction and management of the subways in the hands of a stock company. The ownership of the subways by such a company constitutes one of the chief difficulties in getting the electric companies to make use of the conduits already laid.

The *Evening Post* would have done better service to the public by confining its attack to the Subway Commission and refraining from an assault upon a particular method of distribution; but if it finds itself constrained to antagonize the alternating current system (which we trust is not the case) it would do well in future to submit the work of its reporters to some competent electrical engineer before printing it.

THE time is getting short for the Medico-Legal Society to complete its task of devising the proper method of executing capital offenders by electricity in accordance with the laws of the State of New York. We can not believe that the amiable doctors and lawyers of the society enjoy their labors, which we fear a thankless community fails to appreciate, and we can see no better way for them to discharge their obligation and acquit their conscience than the adoption of the suggestion of the ELECTRICAL ENGINEER, in October, viz., that the whole matter be turned over to Mr. Harold P. Brown. Let the Medico-Legal Society recommend to the legislature the creation of a new office, that of State Executioner, and make Mr. Brown incumbent for life. That gentleman may not be so "sarcastic" as his namesake of Calaveras—he certainly is not so "quiet"— but we have no doubt he will prove as efficient.

If successful in such a recommendation the society will not only have secured the selection of an uncommonly fit person for an important office, and have provided a career for an unappropriated genius, but will have relieved its special committee from further arduous and exhausting labors, such as attend scientific investigation and the preparation of reports like that presented at a recent meeting of the society. Give the job over to Mr. Brown and have done with it, Gentlemen.

THE retiring Mayor of New York, has signalized his administration of city affairs by the courageous exercise of his uncommon common sense, guided by his public spirit, in many practical reforms and improvements conducive to the public convenience and welfare, and now marks his last week of office by an official act that is not only typical of his practical methods, but timely and significant in respect to a prominent public question —that of city transit. In obtaining from the New York and Harlem Railroad Co. an agreement to put down better rails and improved track construction on a section of their line from the post-office, in consideration of his approval of the city ordinance granting permission to use electricity as motive power—together with the further promise of the company to reconstruct their entire line if the experimental section prove satisfactory in use after a fair trial—Mr. Hewitt has done the public a service of high value.

The prompt acquiescence of Mr. Vanderbilt and Mr. Depew in the Mayor's wishes is a very gratifying feature of the transaction. There is a refreshing novelty about such complaisance on the part of a large corporation.

A MYSTERIOUS reference to a so-called "corner in transformers," which is rumored to be about to come off between "two well-known companies," appears among the editorial notes of a recent number of the London *Electrical Review*. It is not difficult to identify one of the parties alluded to as the owners of the Paul Jablochkoff patent of 1877; nor does it require an excessive amount of Yankee 'cuteness to guess that the other is the so-called Grosvenor Gallery syndicate. It is furthermore possible to conjecture through a glass darkly, that the rolé of the traveler from Jerusalem to Jericho is cast for the Metropolitan Electric Supply Company, Limited. The overture it seems is now being played by the orchestra, but before the curtain rises, it may not be out of place to remark that the fun of a tiger-hunt sometimes depends on who does the hunting.

FOR some time past there have been many rumors and much talk of proceedings concerning a consolidation of the two largest incandescent electric light companies. Whatever truth there may be in such reports, it is not worth while to be impatient for the announcement of a result. The preliminaries of such amalgamations are frequently complicated and prolonged by an annoying difference of opinion on a question which once troubled a pair of mariners, who were trying to bring about a consolidation, but as the ballad tells us,

"They'd both be blowed if they'd either be stowed
In the other chap's hold, you see."

THE paper on "Six Years' Practical Experience with the Edison Chemical Meter," read before the American Institute of Electrical Engineers, December 18th, by Mr. W. J. Jenks—which we print in this issue, with the author's revision—will be found full of interest in electric light circles and to customers served from central stations.

We take the liberty of congratulating Mr. Jenks on the manner as well as the matter of his paper. Its value as a record of actual work is enhanced by its entertaining style.

THE committee on transportation of the National Electric Light Association, announce that by arrangement with the Trunk Line Association they have obtained a reduction in railroad fares of one-third for members attending the convention of the association at Chicago in February. The reduction will apply from points east of Niagara Falls, Buffalo, Salamanca, N. Y., Pittsburgh, Pa., Bellaire, O., Wheeling and Parkersburgh, W. Va.

OBSERVATIONS.

MR. THOS. D. LOCKWOOD must add another item to his chronology of "anticipations," electrical or otherwise. Here is an otherwise one from Thackeray's Pendennis, written in 1850: Chapter xviiii. "Nothing would satisfy Mr. Foker, but painting Mr. Buck's door vermilion, in which feat he was caught by the proctor."

* * *

MANY an intended shaft of wit fails of its mark because a reporter, a proof-reader, or an editor knows nothing of the bow strained to give it flight; and cannot, or will not spare five minutes in which to obtain the information; or because the archer himself does not take care to pick up and launch the identical arrow previously chosen for the purpose. In cases where the latter is the culprit, the punishment certainly fits the crime, for he always reads over his own production, and if it reads wrongly the iron enters his soul.

As the Holy Writ hath it, "Offences must needs come, but woe to him by whom the offence cometh."

Here is a specimen from an electrical book which was published in New York in 1886, and which is a most interesting one to read; on page 40—"*Ordinary iron telegraph wire has a resistance of about 18 ohms to a mile.*" On page 41; "*An ohm answers to the resistance offered by 460 feet of ordinary telegraph wire approximately.*"

Both statements cannot be true; and the student naturally wants to know which is, if either?

ARTICLES.

ELECTRIC MOTOR DIAGRAMS.

BY CHAS. L. CLARKE.

In an article entitled "Puissance et Rendement des Moteurs Électriques,"[1] Hospitalier clearly and forcibly explained, and illustrated diagrammatically, the relation which the ratio of counter electromotive force to direct electromotive force bears to the strength of current, to total energy consumed, to energy converted into heat and work, and to the ratio of work to total energy, the last being the expression for the efficiency of the motor. At the time of its publication the article in question attracted much attention and was particularly welcome to those whose efforts were directed to the development of economical motors but who had not the mathematical training necessary to make use of the information in the form in which it was then available. The purpose of the present article is to extend Hospitalier's diagram and to include the important factors of speed, torque, strength of field, and resistance for plain shunt and series motors.

In order that the diagrams shall be mathematically exact, and also general in their application, it is necessary to assume :—

First, that the inductive value of the field varies as the strength of the field current. This is approximately the case when the field magnets are considerably below saturation.

Second, that the inductive value of the field is not altered by variation in the strength of current in the armature circuit.

Third, that the resistances of the armature or field circuits are not varied by change of temperature, or that any such variation is compensated by an adjustable resistance.

Fourth, that the direct electromotive force on the armature circuit is constant.

Fifth, that the field circuit of shunt motors is supplied from an independent generator of constant electromotive force.

From the theoretical diagrams a general idea of the principles governing the operation of motors can be obtained, and to those skilled in the art, the limitations, which must be applied to the theory, to adapt it to practical requirements, will be apparent.

In the diagrams, the horizontal scale represents the value of points on the horizontal line only. This line is the abscissa for all others, the value of the ordinates being given by the left-hand scale for full lines, and by the right-hand scale for dotted lines. The values being expressed in terms of their ratio to unity, the equations from which they are obtained are expressed in terms of the variables only.

SYMBOLS.—FOR BOTH SHUNT AND SERIES MOTORS.

NOTE.—In series motors, the "armature circuit," hereafter mentioned, includes the field circuit.

Direct electromotive force	E
Counter electromotive force	e
Active electromotive force	E^1
Current in armature circuit	C
Resistance of armature circuit	R
Total electrical energy consumed in armature circuit	W
Electrical energy in armature circuit converted into mechanical energy	w
Ratio of w to W	M
Electrical energy in armature circuit converted into heat	H
Speed of rotation of armature	S
Statical moment or torque on armature	T
Inductive value of the magnetic field upon the armature	F

1. *La Lumière Électrique*, 1880, vol. ii., page 305.

SYMBOLS.—FOR SHUNT MOTORS ONLY.

NOTE.—The following symbols apply to the field circuit of shunt dynamos only, it being independent of the armature circuit.

Resistance of field circuit	r
Current in field circuit	c
Electrical energy consumed in field circuit, all of which is converted into heat	h

The mechanical work performed by the motor is $w = e \times C = T \times S$. Of this a certain amount is consumed in overcoming the friction of bearings, resistance of the air, the drag due to Foucault currents, etc. The balance is available for useful work.

SHUNT MOTORS.

CASE I.—CONSTANT ARMATURE CIRCUIT RESISTANCE AND FIELD. (DIAGRAM A.)

The value of e (line F) is expressed in terms of its ratio to E, the latter being equal to unity, or 100 per cent.

$E^1 = E - e$ is represented by line C.

$C = \frac{E^1}{R}$ " " C.

$W = E \times C$ " " C.

$w = e \times C$ " " E.

$M = \frac{w}{W} = \frac{e}{E}$ is represented by line B.

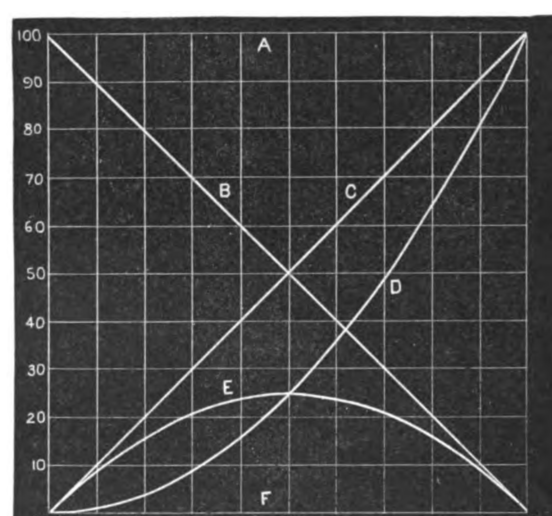
$H = E^1 \times C$ " " D.

The value of F being constant, e must vary as S, therefore,

$S = e$ is represented by line B.

$T = \frac{w}{S} = F \times C$ is represented by line C.

F and E being constant, r, c, h, are necessarily constant and all are represented (as is also the constant R) by line A.



A

It will be observed that when e is equal to E, S and M have their maximum values and that E^1, C, T, W, H and w are each equal to zero. In practice, this is an impossible condition, inasmuch as the friction of the bearings alone requires that T shall be finite. When e is 50 per cent. of E, w has its maximum value and is equal to H. H has one-quarter and E^1, C, W, T, M and S, one-half of their theoretical maximum values. When e equals zero, E^1, C, W, T and H have their maximum values, and M and S are equal to zero. This condition is represented in practice when the armature is prevented from turning.

Economical motors should be so proportioned that, when the value of e is at least as high as 95 per cent. of E, the speed is safe and practical for continuous work. If the load were entirely taken from such a motor, the speed could increase

but five per cent. Therefore a shunt motor cannot "run away," and when the load varies but little from its normal amount, is practically self-regulating.

CASE II.—CONSTANT ARMATURE CIRCUIT RESISTANCE AND SPEED. (DIAGRAM B.)

As in case i., e is expressed in terms of its ratio to E by line F. E, S and R are constant and represented by line A.

The values of the following factors are the same as in case i.

E^1, C, W, are represented by line C.
w is represented by line E.
M " " B.
H " " D.

S being constant, e must vary as F, therefore,

$F = e$ is represented by line B.

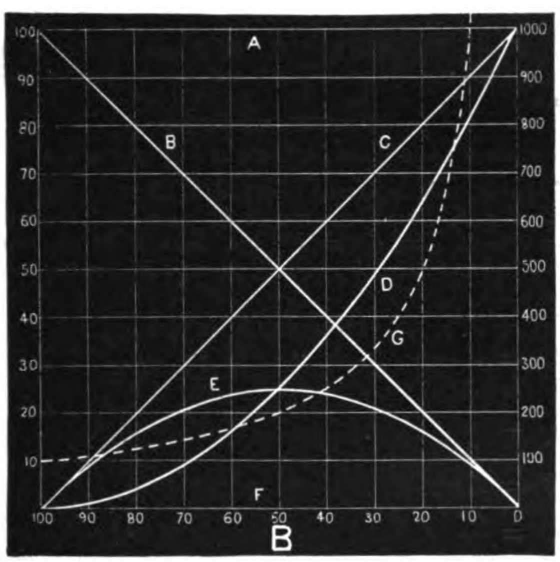
$T = \dfrac{w}{S}$ " " E.

F varies as c, therefore,

$c = F$ is represented by line B.
$h = E \times c$ " " B.

With E constant, F varies inversely as r, therefore,

$r = \dfrac{1}{F}$ is represented by line G.



It will be noted that T varies as w, and that F varies as e. If the load increases, the strength of the field must be diminished for all values of e greater than 50 per cent. of E, and increased for all values of e less than 50 per cent. of E.

In practice T must be finite (case i.), therefore e equal to E is an impossible condition, because T must then equal zero. For the same reason e cannot be equal to zero. A definite strength of field is necessary to start the motor and its speed is maintained constant by field regulation.

CASE III.—CONSTANT ARMATURE CIRCUIT RESISTANCE AND TORQUE. (DIAGRAM C.)

As in cases i. and ii., e is represented in terms of its ratio to E by line F.

E, T and R being constant are represented by line A.

E^1, C, W, w, M, H, have the same values and are represented by the same lines as in previous cases.

$S = \dfrac{w}{T}$ is represented by line E.

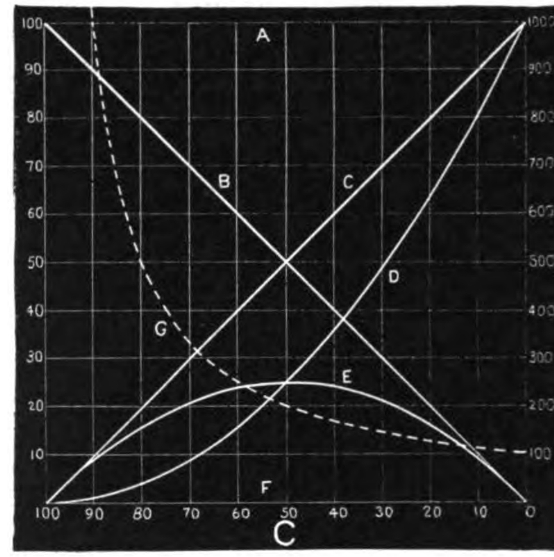
$F = \dfrac{T}{C}$ " " G.

$c = F$ " " G.

$h = E \times c$ " " G.

$r = \dfrac{1}{F}$ " " C.

The load is constant, and if the speed is to be increased, the field must be diminished for all values of e greater than 50 per cent. of E, and increased for all values of e less than



50 per cent. of E. e cannot equal E because the field must be of infinite strength. e will equal zero when the armature is just on the point of stopping. The speed is varied by field regulation.

CASE IV.—CONSTANT SPEED AND FIELD. (DIAGRAM D.)

E, F and S being constant, it follows that e, E^1, r, c and h must be constant, all of which are represented by line A.

It is also evident that the torque, and therefore work of motor, can be changed only by varying the current in the armature circuit. Let the variation of C be represented by the line D, then

$R = \dfrac{E^1}{C}$ is represented by line C.

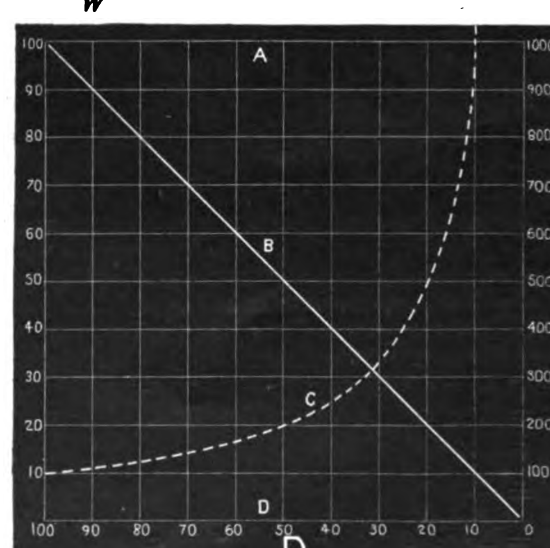
$W = E \times C$ " " B.

$w = e \times C$ " " B.

$H = E^1 \times C$ " " B.

$T = F \times C$ " " B.

$M = \dfrac{w}{W}$ " " A.



Note that W, w, H and T vary as e, and that M is constant.

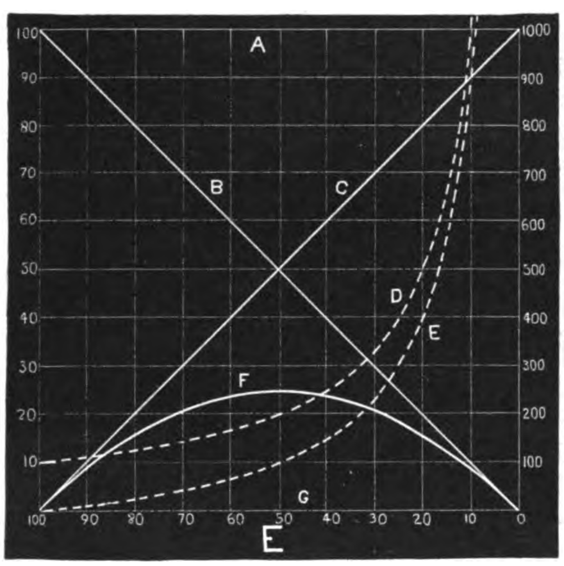
C cannot equal zero because R must be infinite and T equal zero, two impossible conditions. The speed is maintained constant by regulation of the armature circuit resistance.

CASE V.—CONSTANT SPEED AND TORQUE. (DIAGRAM E.)

e is represented in terms of its ratio to E by line G.
E, S and T are represented by line A.
S and T being constant, w is necessarily constant and is also represented by line A.
$E^1 = E - e$ is represented by line C.
S being constant, e must vary as F, therefore,

$F = e$ is represented by line B.

$C = \frac{T}{F}$	"	"	D.
$R = \frac{E^1}{C}$	"	"	F.
$W = E \times C$	"	"	F.
$H = E^1 \times C$	"	"	E.
$M = \frac{w}{W}$	"	"	B.
$c = F$	"	"	B.
$h = E \times c$	"	"	B.
$r = \frac{1}{F}$	"	"	D.



e cannot equal E or zero, because R must also equal zero, which is impossible. The constant speed under constant load is maintained by both field regulation and regulation of the armature circuit resistance. This case has no practical application.

CASE VI.—CONSTANT TORQUE AND FIELD. (SEE DIAGRAM F.)

e is represented in terms of its ratio to E by line D.
E, F and T are represented by line A.
F and T being constant, C must also be constant and is also represented by line A.

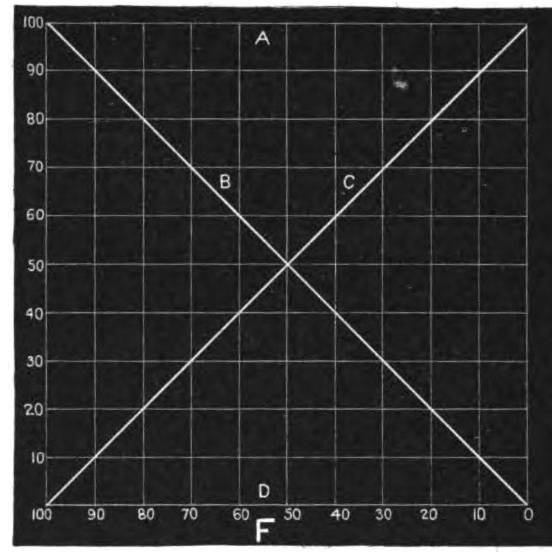
$E^1 = E - e$ is represented by line C.

$W = E \times C$	"	"	A.
$w = e \times C$	"	"	B.
$M = \frac{w}{W}$	"	"	B.
$H = E^1 \times C$	"	"	C.
$R = \frac{E^1}{C}$	"	"	C.

T being constant, w must vary as S, therefore,
$S = w$ is represented by line B.

F being constant, r, c and h must be constant, and are represented by line A.

Note that the speed with constant load and field is varied by regulating the resistance of the armature circuit only.



In practice e cannot equal E, because R must equal zero. e will equal zero when the armature is just on the point of stopping.

If F, S and T; F, S and R; F, T and R; or S, T and R are constant in shunt motors, all other factors will be constant.

SERIES MOTORS.

CASE VII.—CONSTANT TORQUE. (DIAGRAM F.)

e is represented in terms of its ratio to E by line D.
$T = C \times F$. In a series motor F varies as C, therefore, $F = C$ and $T = C^2 = F^2$, but since T is constant, C and F are constant, and C, F, T, and E are represented by line A.

$W = E \times C$ is represented by line A.			
$E^1 = E - e$	"	"	C.
$w = e \times C$	"	"	B.
$M = \frac{w}{W}$	"	"	B.
$H = E^1 \times C$	"	"	C.
$R = \frac{E^1}{C}$	"	"	C.
$S = \frac{w}{T}$	"	"	B.

The speed with constant load is varied by regulating the resistance of the circuit. e cannot equal E, because R must equal zero, which is practically impossible. e will equal zero when the armature is just on the point of stopping.

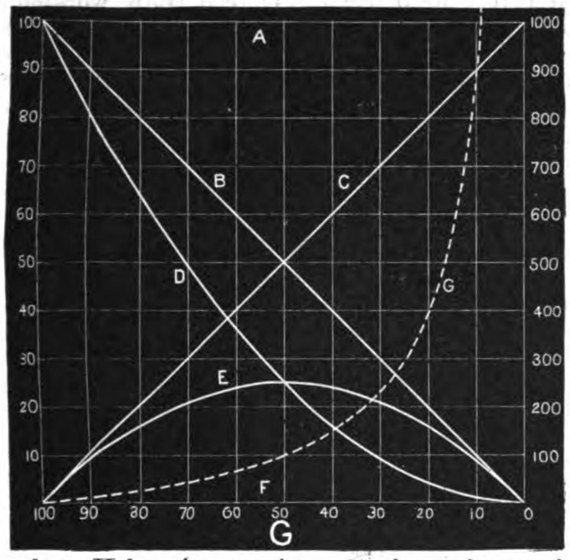
CASE VIII.—CONSTANT SPEED. (DIAGRAM G.)

e is represented in terms of its ratio to E by line F.
E and S are represented by line A.
$E^1 = E - e$ is " " C.
S being constant, e varies as F, therefore,

$F = e$ is represented by line B.

$C = F$	is represented by line B.		
$W = E \times C$	"	"	B.
$w = e \times C$	"	"	D.
$M = \frac{w}{W}$	"	"	B.
$H = E^1 \times C$	"	"	E.
$R = \frac{E^1}{C}$	"	"	G.
$T = \frac{w}{S}$	"	"	D.

The speed is maintained constant, under varying load, by regulating the resistance of the circuit. The field and torque increase and decrease together but not in direct ratio.



Note that H has its maximum value when e is 50 per cent. of E, and that when e is greater than 50 per cent. of E, H diminishes as the load increases.

e cannot equal E because R must equal zero. e cannot equal zero because R must be infinite.

CASE IX.—CONSTANT RESISTANCE. (DIAGRAM H.)

e is represented in terms of its ratio to E by line F.

E and R are represented by line A.

$E^1 = E - e$ is " " C.

R being constant, C and therefore F will vary as E^1, therefore $C = F = E^1$, and C and F are represented by line C.

$W = E \times C$ is represented by line C.

$w = e \times C$ " " E.

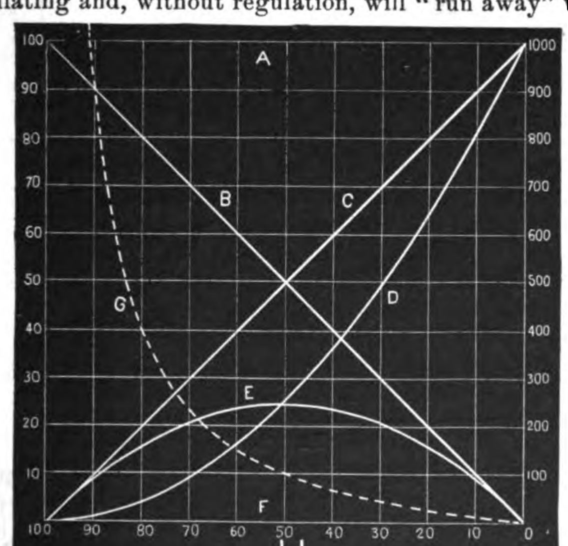
$M = \frac{w}{W}$ " " B.

$H = E^1 \times C$ " " D.

$T = F \times C$ " " D.

$S = \frac{w}{T}$ " " G.

Note that with constant resistance the speed becomes infinite when load equals zero. A series motor is not self-regulating and, without regulation, will "run away" without load. e cannot equal E, because T must equal zero. e will equal zero when the armature is just on the point of stopping.



CASE X.—CONSTANT FIELD.

If E is constant, C must be constant. It necessarily follows that all other factors will be constant. This is based upon the assumption already made that F varies as C.

If S and T, S and R, or T and R are constant in series motors, all other factors will be constant.

If the field magnets of series motors are saturated so that it may be assumed that the inductive value of the field is constant for all variations in the strength of current, then cases vii., viii., and ix. are represented by cases vi., iv. and i., respectively, omitting, of course, any consideration of the factors r, c, h.

SIX YEARS' PRACTICAL EXPERIENCE WITH THE EDISON CHEMICAL METER.[1]

BY W. J. JENKS.

"MEASURE FOR MEASURE" has ever been the underlying principle of the trade of the world. The mess of pottage for which Esau bartered his birthright was as truly in his eyes a recompense for the distinction and the patrimony with which he parted, as the property and the necessaries of life which we acquire are in our view an equivalent for the gold and silver which we pass from hand to hand in every-day exchange.

If we start out in life with the notion, so fondly cherished some time or other by every human heart, of getting something for nothing, we shall speedily realize the truth of what somebody has happily expressed in verse :—

> The motto of the world is "give and take,"
> It gives you favors, out of sheer good will;
> But unless speedy recompense you make,
> You'll find yourself presented with its bill.

We are not in business matters long contented with any system of guess-work as to what the amount of this bill ought to be. Where values cannot be measured, we demand averages based upon long experience. Where it is possible to measure goods delivered, the ingenuity of man is untiring until some means is found adapted to the uses of all the traders of the world. It is only so far as we can draw from nature's limitless supply of necessaries and blessings "without money and without price" that we fail to find in these days a meter check upon our consumption. As long as people live in civilized communities, water and artificial light will represent somebody's labor, and as they come to be more and more generally used, they must be more and more accurately measured.

Perhaps it has never occurred to many of us that about the only system of measurement that has ever quite satisfied mankind is the method or device by which we reckon the passage of time, which doesn't cost us anything. We look with suspicion on the scales of the butcher, and we don't believe the milkman's quart is more than two-thirds as large as it was years ago, though the price has advanced several per cent. When we buy dry goods we speculate on whether it isn't best to redetermine the length of a pendulum that will beat seconds at the level of the sea, or establish a new yard on the metric basis, after we measure the distance from the equator to the poles again. We know by the ticking of the water-meter that it is away off any standard, and last and oftenest we anathematize the gas meter and the man that reads it as being alike unsanctified.

Now the electric current meter is a baby yet, but it is very likely to be considered by the great majority of mankind as a direct descendant of the gas meter—"a chip of the old block." Unfortunately we cannot record directly the light or power really delivered from any source, and an approximation to such a record through the measurement of the quantity of energy supplied, is our only practical alternative. The method which we shall examine to-night,

1. Read before the American Institute of Electrical Engineers, New York, December 18th, 1888.

is thus far the only commercially successful means of measuring the energy delivered to electric lamps or motors. It is doubtless the first-born of a large family which will share in the stigma which the tribe of meters of all kinds has always borne. To show how far the stigma in this case is undeserved, and how much more accurately we can measure the mysterious intangible something, which we only know as a manifestation of energy and which we call electricity, than we can measure the palpable forms of matter which are apparent to all the senses, is the purpose of this paper.

In the approximation which we make to the measurement of the light, heat or power secured from gas, we have three variables: quality of gas, rate of flow, and form of burner or method of consumption. In electrical work we eliminate at once the first and one of the most uncertain of these variable factors, for there is no difference, so far as we can discover, in the quality or commercial value of electrical energy from different sources, unless we change the method or the rate of its delivery (as, for instance, send it out in intermittent or alternating impulses).

So in order to arrive at a price at which we may profitably sell light or power, we must know the electrical horse-power demanded by the translating device for a given result, that is the efficiency of the lamp or motor and the energy actually delivered, during the time of consumption. The work done or heat generated, which bears a definite relation (in a given type of lamp or motor) to the light or power produced, is expressed in three factors—pressure, current flow, and time; and the product of these, joules, or units of work accomplished in a given period, is what we desire to measure. In the Edison system the light of the lamp and the speed of the motor are based upon the supply at their terminals of a constant pressure, and as the Edison meter is in its relation to the resistance of the circuit practically at the lamp or the motor, it may for all commercial purposes be regarded as always acted upon by the constant standard of E. M. F. applied to the device which transforms the electricity to the useful energy of light or motion. Hence we really make this a joule meter, even while we drop the pressure which is a constant, and make it a measurer of current and time, or a coulomb meter. Its construction is based upon the fact that a given ampere flow will deposit a given weight of metal per second, and so knowing the weight of zinc deposited on a plate, it is easy to calculate the number of ampere seconds. In practice we take the hourly deposit (1224 milligrammes of zinc by one ampere), and knowing the fraction of an ampere required for the standard lamp, we can readily arrive at the lamp hours for which the customer should be charged. It is now becoming common to charge so much for an ampere hour, and sometimes the price is the same whether supplied to lamps or motors, which are thus often included within the registration of one meter.

It is in a comprehensive system of house to house supply, where every unit of light or power is made separately controllable, that the necessity for such a meter appears most vital.

The records of the patent offices of almost all the civilized countries of the world bear witness to the fact that the method of connecting lamps, motors or similar translating devices in multiple arc (the only commercial method of attaining this individual control of current actuated by safe potentials) was original with Mr. Edison. But beyond this there is no question that we owe to him the first comprehensive conception of that form of multiple arc distribution which by combining a low resistance armature, a feeder system of transmission, and a high resistance lamp and motor, has made it possible for us to secure at all lamps and motors a marvellously close approximation to uniformity of pressure, and the expenditure of the largest economical percentage of the initial pressure in overcoming the resistance of the carbon filament, or the counter-electro motive force of the motor armature, and thereby producing the greatest amount of useful work.

To Mr. Edison's view each detail of such a complete system appeared full of importance, and so we find him, almost before he had a commercial lamp, working on a meter by which each customer's consumption could be accurately determined, and which could be placed on his premises and inspected at such intervals as experience had shown were reasonable in the supply of the other measurable quantities, gas and water. He foresaw that it must not only be accurate, but cheap and durable. In his study of the subject he applied several principles of motion and registration, tried a great number of experiments with each, and secured several patents. Among them are the following:—

Fundamental electric motor meter.—Patent 242,901. Application filed March 3d, 1881. Figure 1 shows an old example of a large class of meter inventions in which some kind of an electric motor driven either by part or all

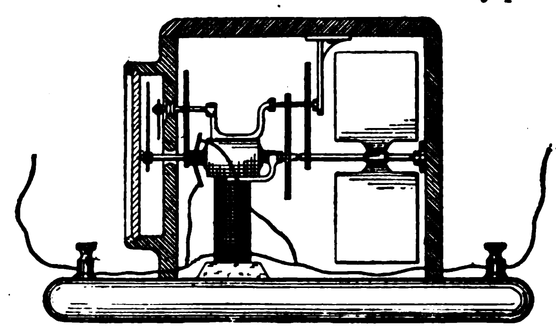


FIG. 1.

of the current to be measured, is employed to overcome a fluid friction, but the claims cover broadly the combination of a circuit, motor, fan, or other definite loading, and registering apparatus.

Figure 2 shows another form of electric motor meter. Patent No. 370,123. Applied for April 17th, 1883. The form of motor used is a development of "Sturgeon's wheel," the wheel being transformed into a cylinder surrounding one pole of the magnet, itself being surrounded by the other pole. In this meter the indefinite friction is reduced to a very small factor, brushes are replaced by mercury contacts, and a very compact and simple form is possible. Probably if mercury did not have such a

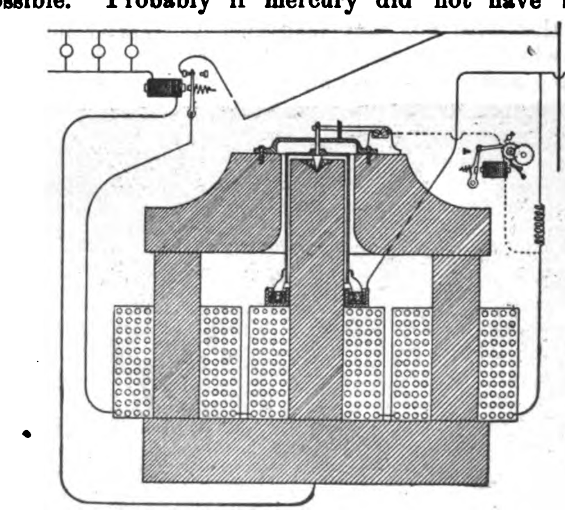

FIG. 2.

chronic disability to behave itself in practical continuous work, and if it really possessed the ideal character of a liquid which it commonly gets credit for, we would have seen this meter put into practical use by some one of the many inventors who have given it attention. This patent covers, among other things, the placing of the inductive portion in the direct circuit and the fields in multiple arc

therewith. A magnet in the main circuit closes the field circuit whenever the first lamp is attached, thus stopping the motor whenever the current flow is arrested.

Galvanometer recorder.—Patent 307,030. Application filed Oct. 10th, 1883. Figure 3. This covers broadly a multiple arc circuit, a galvanometer in the main line, a circuit

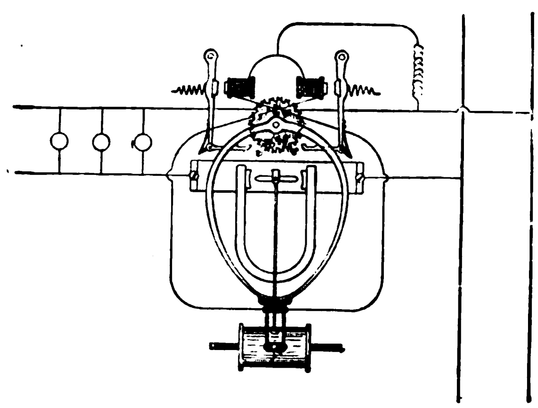

FIG. 3.

controlled by the needle, electrically operated apparatus in this circuit, and indicating or registering devices. Preference is given to a stylus recorder, the diagram made to be measured by a planimeter.

Recording electro-mechanical meter.—No. 293,435. Applied for August 14th, 1882. Figure 4 shows a pivoted beam oscillated by electro-magnetic coils in the main or a

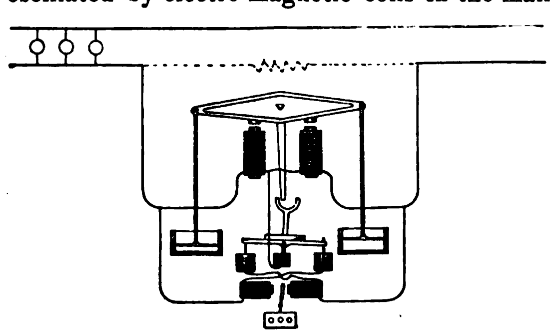

FIG. 4.

shunt circuit, the rapidity of motion (regulated by air dash-pots of large surface) being practically proportional to the strength of the current. The recording mechanism actuated by a local circuit operated by mercury contacts.

Fundamental electrolytic meter patent.—No. 251,545. Application filed March 20th, 1880. Figure 5 shows the electrolytic meter according to the first Edison patent. An electro-magnetic cutout is shown and claimed as part

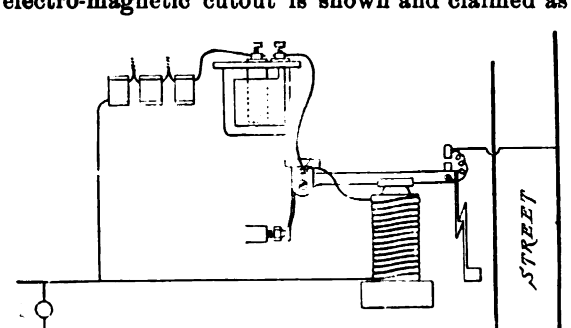

FIG. 5.

of the meter. The principal claim covers the use of an electrolytic cell placed in a shunt circuit, the resistances being so proportioned that a definite fraction of the current passes through the cell.

Recording electrolytic meter.—No. 304,082. Application filed August 14th, 1882. Figure 6. At the time of the Paris Exposition of 1881 the Edison meter was exhibited in the form of an automatically recording apparatus, two electrolytic cells being used, one plate of each suspended from the beam of a sensitive balance, the circuits being so arranged that one cell only is in circuit at a time and the direction of current in that cell is such that the electrolytic action will throw the balance out of equilibrium, cause the beam to "kick" and by that action throw the current to the other cell and register one on the counter. Whether this form was seriously intended for general use may be doubted,

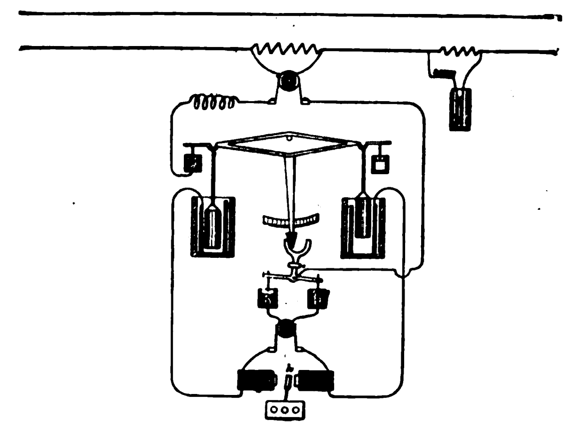

FIG. 6.

but it was very carefully worked up, several different forms patented, and it attracted a great deal of attention and well deserved admiration in its time. Figure 6 shows plainly the general form and the connections. The counter is operated electrically by the motion of the index of the balance; contacts are made in mercury cups; dash-pots regulate the motion; reversing commutators, operated by hand once a month, keep the transfer of copper from plate to plate from going always in one direction. A simple electrolytic cell is used as a check. This is probably significant of the inventor's lack of faith in mechanical meters, and is particularly interesting to look back upon, in the light of subsequent progress.

Revolving recording electrolytic meter.—(Still pending in the patent office.) Figure 7 shows an interesting modification of an integrating electrolytic meter, in which between two electrodes immersed in the electrolyte is placed a wheel or cylinder of the same metal, free to re-

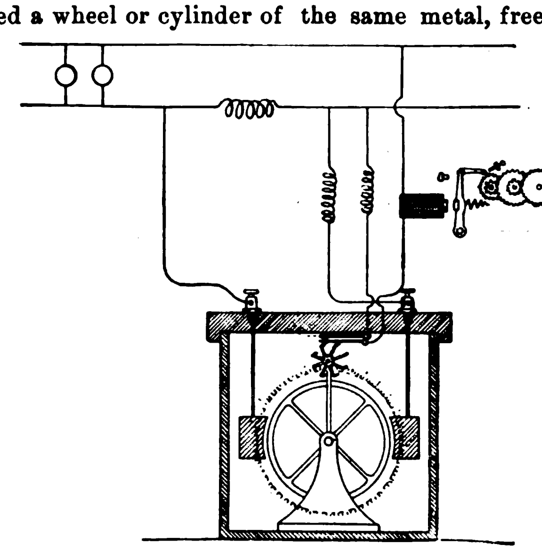

FIG. 7.

volve on its axis. It is apparent that if the wheel were perfectly balanced and delicately poised, the passage of a current would alter the balance, and it would revolve at a speed depending almost entirely on the friction of its bear-

ings. But if it were first caused to revolve at a definite rate for one-half a revolution, the lower limb moving in the same direction as the current, there would be a deposit and loss on opposite halves of the periphery, causing a variation of position of the centre of gravity around the point of support, causing the revolution to continue at the same rate for the same current or at a rate proportional to the current.

The diagram shows a dial scale for reading fractions of a turn and an electric counter recording complete revolutions.

Floating electrolytic cell.—Patent 248,565. Application filed December 15th, 1880. Figure 8 shows a eudiometer intended to decompose water, collect the mixed gases in a bell-glass, and when a definite quantity is evolved by the raising of the glass automatically cause recomposition (and consequent falling of the glass) by closing a circuit through a platinum coil which becomes heated thereby. This operation is to be repeated continuously

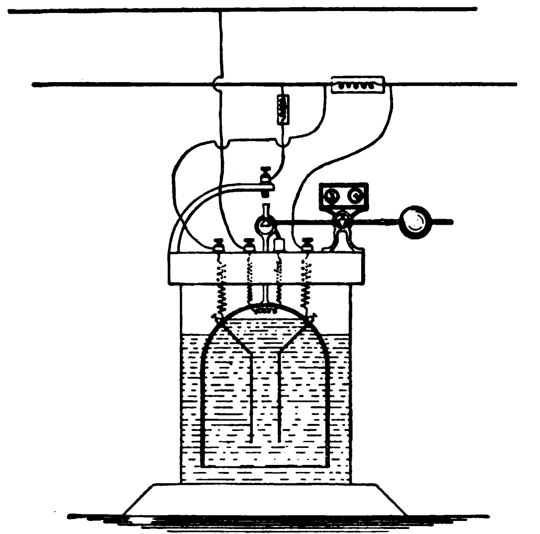

FIG. 8.

while the current is passing, a counter giving a record of the number of charges of gas exploded.

Among the difficulties of using such an apparatus are the comparatively high E. M. F. required, the energy wasted, and possibly like the nitro-glycerine engine, "the necessity of providing a new machine after each explosion." A very similar apparatus has been recently proposed as a laboratory standard for current measurement.

Automatic temperature regulator.—No. 251,558. Filed August 30th, 1881. This patent, illustrated in figure 9, covers important features of the Edison meter of to-day. Briefly, these are: (1) the resistance E acting as a

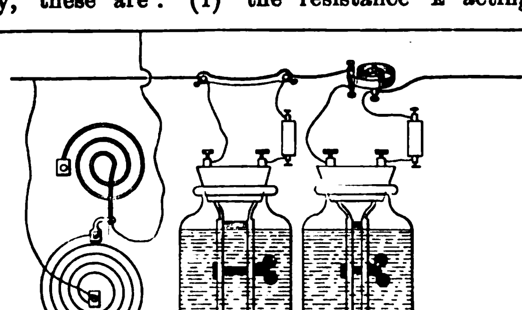

FIG. 9.

source of heat to prevent freezing of the liquid in the bottles; (2) the thermostat G completing circuit through E at the proper degree of temperature; (3) distance pieces for holding the electrodes a fixed distance apart.

Fundamental temperature regulation patent.—No. 265,-774. Application filed November 11th, 1881. Figure 10 illustrates a method of generating heat by the action of a thermostat energizing an electro-magnet controlling a valve, which being opened permits water to flow upon quick lime. This is one of the methods illustrative of the broad idea of "causing a fall in the temperature to set in action agencies for generating heat," and thus maintaining automatic temperature regulation in an electrolytic cell.

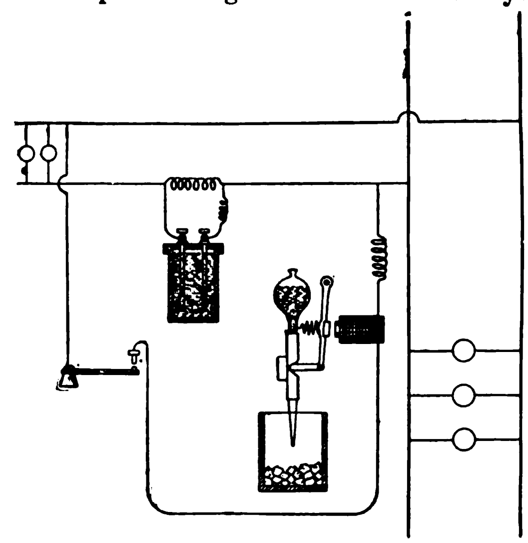

FIG. 10.

Another method here described is the one now practiced, the closing of "a circuit to an electric lamp placed in proximity to the cell." On the same date of this application Mr. Edison filed Patent No. 281,352, describing one of the most vital features of the practical apparatus, namely, amalgamated zinc electrodes in a solution of sulphate of zinc. This overcame the disadvantages of copper plates, which had formerly discouraged the inventor.

Compensating coils in electrolytic meters.—No. 251,557. Applied for May 27th, 1881. Figure 11 illustrates certain minor claims of details, some of which apply to the Edison meter of to-day, and one feature without which probably no electrolytic meter would be practical, the "compensating spool" having a + temperature coefficient to balance the — coefficient of the bottle resistance. This patent

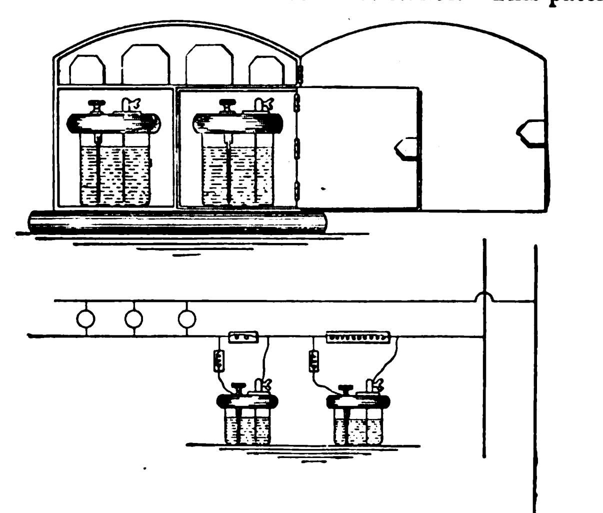

FIG. 11.

rlso covers the use of two cells, depositing with unequal rapidity.

The original plan involves, of course, only a two-wire meter. This was first made with a separate resistance for each bottle, one of them being intended to register a

month's consumption, the other three months. It was also proposed that the two compartments have separate keys, the inspector of the three months bottle thus having a private check on the three readings taken in the same time from the other side. It was soon found preferable to weigh both sets of plates together, particularly as inexperience in the manipulation gave rise to errors against which the duplicate records formed a check of great usefulness. This duplication has been found unnecessary in the smaller sizes.

The student of the meter question may find interesting modifications of these general principles in patents 240,678, 281,352, and others.

These sketches and the patents enumerated convey a faint idea of the months of patient analysis, the multitude of experiments and the scores of models and drawings which may be found described in Mr. Edison's note books, many a page written by his own hand years before the electrical fraternity conceived of the importance of these devices for which the world now loudly calls. The electrolytic principle was finally determined upon, the details perfected, and more than six years ago the first devices were placed in the offices and stores of the first customers of the Pearl st. station in this city, the first station in the world to distribute current for incandescent lamps by a comprehensive system of conductors buried underground like gas pipes. The experiments thus made were so exhaustive and thorough in their character, that the meter then designed is substantially the one in use to-day in

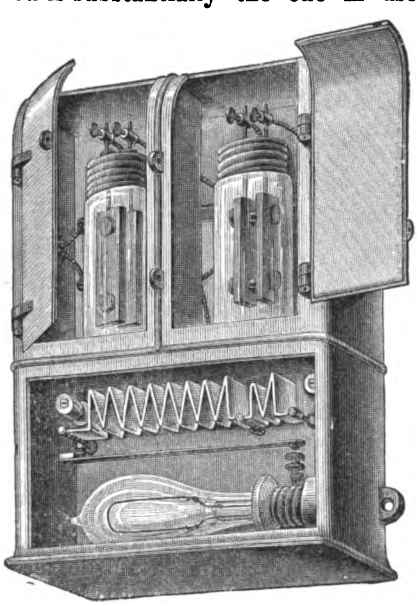

FIG. 12.—Old form of two-wire meter.

numerous stations throughout the United States and several stations in foreign countries. The Edison company has tested every form of direct current meter thus far found in any degree practicable without discussing (as vital) the question of economy either in first cost or operation, and has no knowledge of any other form which has been found to be as accurate under all working conditions, and as reliable when submitted to that tribunal before which so many carefully constructed electrical devices fail,—the test of time. The Edison meter is also cheap, but this is of less vital importance. All other forms appear to be commercially impracticable. Some have inherent de fects, caused by variations of permanent magnetism. Some are too large to be of any value for commercial use, and they are almost, without exception, too costly and delicate for practical service, or too wasteful of the energy they demand for their operation. We have abundant evidence of the justice of these statements when we remember that out of the many meters thus far proposed, there is not another which has come into anything like extended use.

The record which we can quote is therefore the only one from which any conclusions can be drawn as to future practice in this direction.

We shall be better prepared to appreciate the results obtained after glancing at the distinctive features of the meter as at present constructed.

Figure 12 shows, in an iron case, the form of meter placed at the time of starting the first district station, September 4th, 1882. The division in the german-silver shunt resistance for the long and short period bottles has given place to a method of connecting both to the same terminals. The flexible connections have been superseded by the spring clips, and in the three-wire meters two shunt resistances are placed, as in figure 13.

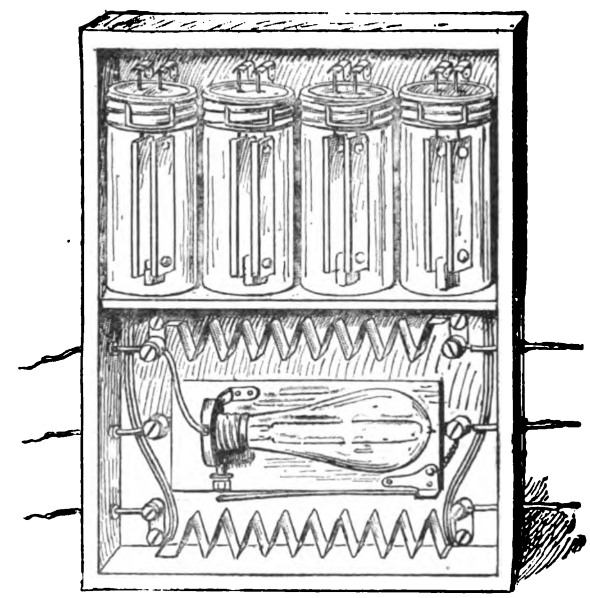

FIG. 13.—Three-wire meter, open.

Stripped of all complications, the connections of these types are clearly shown in the diagram, figure 14.

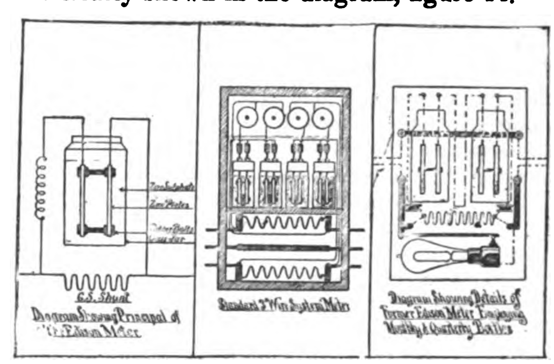

FIG. 14.

The meter case is made of well-seasoned hard wood specially prepared to expel air and prevent warping, and to maintain high insulation ; the door of heavy sheet iron properly lettered and numbered. This is held closed by a metallic button turning upon a small post, both passing through a vertical opening. The wire of a lead seal is passed through the button.

The conductors enter and leave the meters through holes in the side or bottom, about two or three inches apart.

The thermostat is required for all meters situated in locations where the solution is likely to freeze. It is furnished as an extra attachment and may be inserted in any size meter, and to it is attached a small contact point connected with a lamp socket. Into this socket is screwed a lamp, and when the temperature in the meter falls below a certain point it will cause the thermo strip to curve up, bringing the two contact points together, closing a circuit

through the lamp and heating the interior space. As the temperature returns to normal the strip straightens and the lamp is cut out. The adjusting screw in one complete revolution changes the elevation of the contact point $\frac{1}{16}$th of an inch, and being made with a six-sided head (numbered), $\frac{1}{6}$th of a turn will change the absolute temperature standard of contact about two degrees Fahrenheit. Thus the adjustment may be made sufficiently close.

The cells are partially filled with a 10 per cent. zinc sulphate solution, no special effort being made to render them air-tight, except so far as to prevent evaporation. In these the zinc plates are supported by ebonite distance pieces, screws and nuts, and connected by copper rods with spring clips fixed in the top of the space.

The resistance in the main circuit is of german silver, of the quality used by Elliot in his bridges, and so proportioned as to allow $\frac{1}{975}$th of the current to pass through the cell and its compensating spool.

The small portion of current passing through the bottle removes from one plate and deposits upon the other metallic zinc, which when its weight is ascertained determines the current transmitted.

The two-wire meters authorized to be used with the three-wire system, are of two sizes only, five and ten amperes capacity, respectively. Anything larger than five amperes may be preferably divided to balance the two sides and hence they are made of five amperes each side; capacity, 20 of the present 16 c. p. lamps; 10 amperes, 40 lamps; 20 amperes, 80 lamps; 40 amperes, 160 lamps; 80 amperes, 320 lamps.

This will be made more clear by a

TABLE OF SIZE AND CAPACITY OF METERS.

Meter No.	Maximum ampere capacity.	
0	5	2-wire meter for 5 amperes.
½	10	" " " 10 "
1	10	3-wire meter for 5 amp. on each side.
2	20	" " " 10 " "
4	40	" " " 20 " "
8	80	" " " 40 " "
16	160	" " " 80 " "

In selecting the proper size of meters for certain customers it is borne in mind that a meter plate has, like a storage battery, a somewhat definite maximum capacity in ampere-hours per month. The standard found most desirable is 150 milligrammes deposit per month per ampere of nominal capacity.

The normal capability is therefore understood to be restricted to an average work of one or two hours per day at this maximum load, which corresponds with practical work. If steady work is to be done for an average of three to four hours daily, the load should be about 20 per cent. less; if from five to six hours, about 25 per cent. farther reduction should be made to determine the proper limit for a given plate.

The meter is, in practice, placed in all sorts of positions. The general instructions simply provide that it shall be kept clean and dry, inside the service fusible cut-out, and easy of access.

The initial preparation of plates consists simply in thorough cleaning, covering the top and about an inch of the rod with a coat of asphalt varnish, amalgamating and drying (three coats when new), weighing and tagging of the positive plate, and placing in the solution.

When removed the plate is re-weighed, and where two bottles are used their weights are compared by the meter man and his record sent to the book-keeper or superintendent.

The loss in milligrammes sustained by the positive plates is then multiplied by the meter constant which gives the bill in dollars and cents. This constant is found as follows:—

Let \$ equal price of one standard lamp hour.

C equal ampere capacity of standard lamp.

Then current through the bottle equals $\frac{C}{975}$

As 1224 milligrammes (of zinc) is represented by one ampere-hour, one standard lamp hour is equivalent to $\frac{1224\ C}{975}$ milligrammes, at the price \$. Hence the price for current which has removed one milligramme of zinc will be :—

$$\frac{\$}{\frac{1224\ C}{975}} \text{ equals } \frac{\$ \times 975}{1224\ C} \text{ equals constant.}$$

Each consumer has a meter upon his own premises, and his bill is made out and payment required upon what the meter shows. To measure the current by means of a meter, and to do so with sufficient exactness to support a bill, the payment of which was to be insisted upon, at first seemed to many of the customers of our various companies an impossibility, and they accordingly resorted to various devices for the purpose of testing the accuracy of the measurements themselves. The most noteworthy of these, for the reason that it affords a simple and effective check, was to keep a record of the hours each lamp was in use, and by multiplying this number by the given rate of a sixteen-candle lamp per hour, to determine what the amount of the bill ought to be. There have been many instances where, in order to satisfy customers that the meters were reliable, we have taken their record at the end of a given time, during which the customer has kept an account of his lamp hours, and have presented bills upon what the meters showed, that the customer might check the amount of his bill by this simple rule.

It has been argued that the Edison chemical meter, in its best estate, is open to several very serious objections :—

1. The necessity of the expense attending the removal and replacement of the bottles, usually at monthly intervals, and the complete disconnecting and weighing of their plates. So far from being a detriment, this is seen to be in the light of practice a positive advantage. A gas meter is adjusted once for all, and once placed is inspected only at long intervals, or when strongly suspected of inaccuracy, while the Edison meter receives thorough inspection and radical readjustment every month. The sources of error lie almost entirely within the bottle, and are thus speedily corrected.

2. The necessity of employing what objectors are pleased to term a "chemist" as a meter man. In the early history of any art, until the conditions of practice become thumb rules, the manipulator of an important device should be a man of intelligence and some originality of ideas. After a time the work becomes simply a matter of routine, and the occasional oversight of the manager or other official will detect any irregularities. Thus it has been with this branch of our work. The most of our meter men are young, and receive only moderate pay, as the statement of cost of operation elsewhere given, conclusively shows. Accuracy and caretaking in matters of detail are the prime requirements. The work has been greatly simplified by arrangements with Mr. Edison, by which electrolytic zinc plates, standard zinc sulphate solution in carboys (or salt, if preferred), distilled mercury and four simple reagents, for the testing of water for solution by such companies as prefer to prepare it themselves, as a matter of convenience or economy. These reagents are :—

(1) Ammonia water.
(2) Ammonia sulphide.
(3) Nitrate of silver, and
(4) Sulph. cyanide of potash,

a few drops or a small crystal of each, as the case may be, to be added to separate portions of water. Any meter

man can thus make the four simple tests, which, by a precipitate or by cloudy coloration, will show the water to be unfit for use.

Ordinarily, ice water is available, and where this fails, a simple apparatus for condensing and distilling, costing $25, is sometimes desirable.

Sources of error.—This brings us to the consideration of the real importance of the sources of error. Nothing that man has made is free from some of these drawbacks to accuracy, but when we except those mechanical imperfections common to all electro-mechanical devices, it is surprising how few appear which play any important part in the result, and how far these few are neutralized. In order to point the application of the few facts and diagrams to be shown, let us refer briefly to the criticisms made on this much-misrepresented but important friend of the Edison manager.

From the English *Electrician* of December 16, 1887 :—

"Edison calculates the total consumption of current by passing a known (or supposed known), fraction of the total current through the meter, and the energy supplied is calculated on the assumption that the difference of potential is constant throughout the circuit. This assumption is, of course, only approximately correct."

From the same journal, December 30, 1887 :—

"In the third edition of Sir David Salomons' work on the 'Management of Accumulators,' the author (on page 105), gives the following definition of Edison's meter : 'A thing of the past, depending upon the deposit of some metal.' We are, unfortunately, a little doubtful as to the immediate accuracy of the first part of this description, inasmuch as we are under the impression that this apparatus is still extensively employed by the Edison company of the United States; but in the light of the statements alluded to above, there can be but little doubt that Sir David's description will, sooner or later, be perfectly accurate. As to the 'deposit of some metal,' which appears at present somewhat erratic, we suppose the balance is made up on the settlement of the account. But if these accounts have any foundation, it is perfectly clear that the error is entirely against the company. As we recently had occasion to remark in our articles on the Brighton installation, the Edison plan, by which a fraction only of the current supplied is measured, can be accepted as little better than a makeshift at the best."

One more quotation (from the *Electrical World*, of a little more than a year ago—Oct. 22, 1887,) of some remarks made at one of the meetings of this Institute. It is especially desirable to bear them in mind, as an illustration of the idea that a little knowledge and a great deal of theory on any subject is a dangerous thing in the light of actual experience :—

"There has been already a great deal of time and a large amount of money spent on electric meters for direct currents, and I do not think we have had any current meters of any value whatever.

"The electro-chemical system, in use by a very prominent company here, was put out with a great deal of confidence with the results to be obtained from it. I think any one looking at the principles involved would condemn it from the start. You are to take a small fraction of the total current, and a very small fraction indeed, and pass it through an electrolytic cell, the character of which varies from time to time, so that the resistance is never fixed, and pass the bulk of the current around a resistance which is practically fixed. The change in the resistance of the metal would be but a small proportion of the change in the resistance of the electrolyte. Now in such an instance as that you are measuring a very small fraction of the current passing, and whatever error you have are multiplying that error by the fraction. If you are measuring 1-1000 you are multiplying your error by 1000. Any one who has had much to do with electro-metallurgy knows that the cells are constantly changing; that to keep the deposit regular and uniform, to keep the resistance of the solution uniform, they must be constantly attended to. There is not an electro-plater in the country who does not once in a while go in and stir up his baths. Such an instrument is of no real value. We may, therefore, dismiss those instruments entirely from consideration, I think.

"If any one will take the record of the patent office on electric meters, he will see that there has been no small amount of time and thought and money spent on that question. Practically, we are in the same position we were before. We had nothing except the electro-chemical meter, which, as I say, I consider entirely worthless."

The lack of information on this subject, thus illustrated, will be seen more clearly by an analysis of the actual value of the sources of error.

Oxidation.—In the hands of an inexperienced person almost any method or device, good and reliable in itself, may be misapplied so as to gain an unenviable reputation. An Edison meter cell may be so manipulated as to measure almost any resistance and vary between wide limits. A few practical rules have, however, been applied, and the bugbear which has so disturbed the visions of those who have looked at the matter from a theoretical standpoint only has disappeared. In other words, we are able to reduce practically to nothing this error, and it therefore appears in the results only as a slightly disturbing element at the lower end of the deposit curve, and always against the company.

The german-silver shunt.—The extract I have read specifies quite distinctly the slight error introduced by the change of resistance of the german-silver shunt with temperature variations. For each 25 degrees Centigrade or 45 degrees Fahrenheit this variation is but 1 per cent. Within a range of 40 degrees it is 0.0249 per cent. for each degree (Fahrenheit). A shunt having 0.01 ohm at 60 degrees Fahrenheit, would be at −2 degrees Fahrenheit 0.00984 and at 100 degrees Fahrenheit 0.01009 ohms. The maximum error which can ever occur is about 2 per cent., due to a change from freezing to 120 degrees Fahrenheit, the maximum reached in any of the meters at full load. As a matter of practice, meters are so placed as to vary not over 30 or 40 degrees, on the average, either from atmospheric changes or the heating of the current.

Counter electromotive force.—Figure 15. It is plain that the change due to a rise of current in the meter here

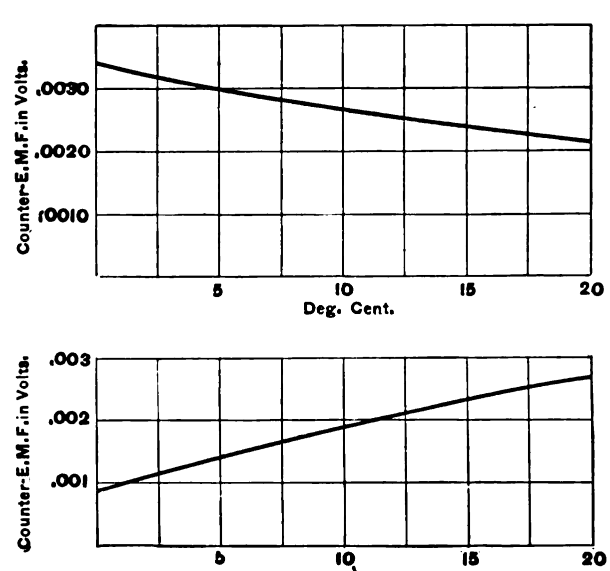

FIG. 15.

illustrated, from 0 to full load or 20 amperes, is 0.0017 volt. As this counter E. M. F. appears in practice as a factor of

resistance, its effect is shown in the current resistance curve.

It is also clear that the error due to the rise in temperature from 0 degrees to 20 degrees Centigrade is 0.0012 volt. This is one of the factors in the temperature resistance curve and is there expressed in ohms.

Bottle resistance and current.—The two errors, increase of counter E. M. F. and consequent rise in potential difference, and decrease of absolute resistance and consequent drop in

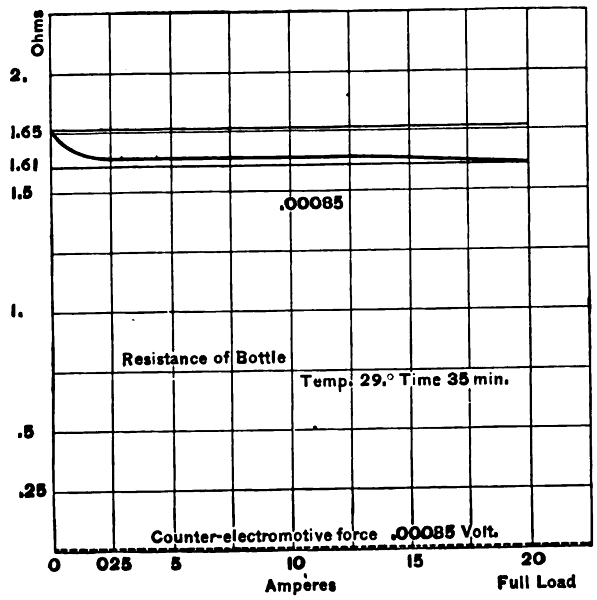

Fig. 16.

potential difference, jointly resulting from an increase of amperes, about balance each other, forming a beautiful compensation which makes this curve almost a straight line. Figure 16.

Temperature compensation.—Figure 17. Considering the bottle resistance by itself, the fall in counter E. M. F.

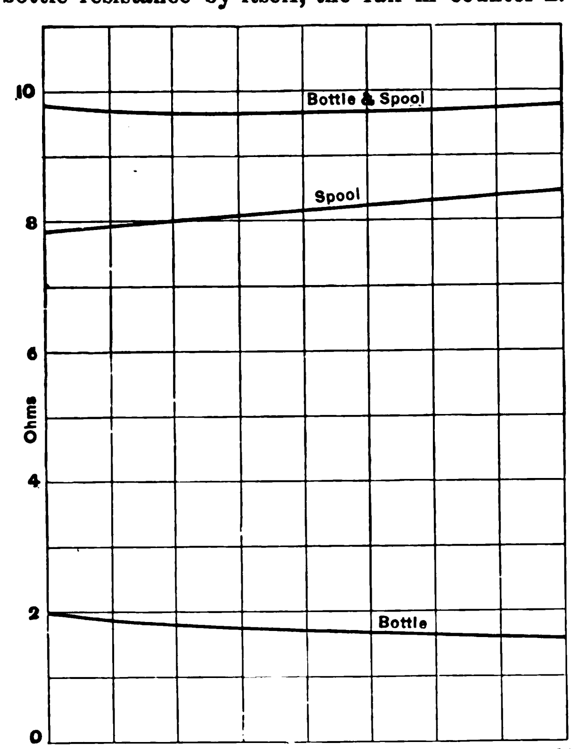

Fig. 17.

and consequent drop in potential difference with a rise in temperature, adds slightly to the drop attending the fall in resistance. These two factors are together opposed by the influence of the spool, whose copper wire increases in resistance so as to make a perfect compensation at 10° and 30° Centigrade with a slight bend in the curve at intermediate points.

Rate of deposit and current.—Figure 18. This curve, the result of the combination of the sources of error shown by the others in detail, is so close an approximation to an absolutely straight line that it is difficult to detect any material departure excepting the slight bend at the minimum load. Into the depth and sharpness of this bend the element of time enters, but after passing this point the curve runs almost absolutely straight to a maximum load.

It is especially noticeable that the curve begins at absolute zero, while with Mr. Edison's early meter of the electric motor type, and others that have followed this principle, the theoretical curve is as shown by the dotted lines. No curves deduced as are the above from long practical work have ever, so far as we can learn, been formulated of the performance of any other meter.

It is proper to say in this connection that the percentage of error from these causes is practically constant for all sizes of the Edison meter.

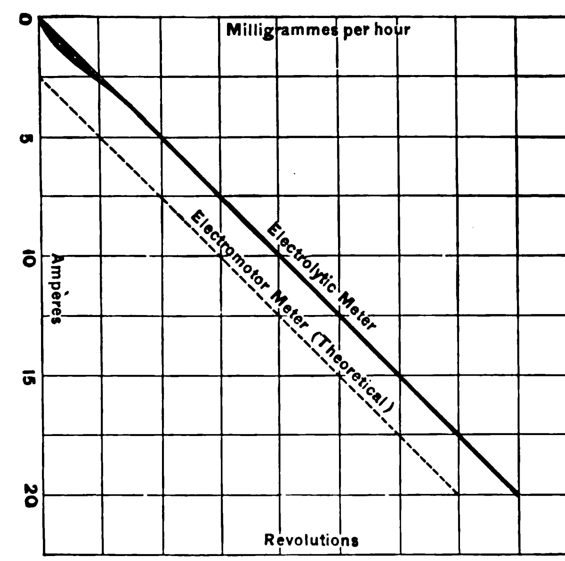

Fig. 18.

Some months ago a very careful test, covering five months, was made by the engineering department. Six Edison meters were connected in series with the meter of the Edison Electric Illuminating Company from the station by which the current is supplied to the offices occupied by the parent company. At the close of this test it was found that all of these meters registered within 1½ per cent. of each other.

An elaborate test was conducted at New Brunswick, N. J., by Mr. W. S. Howell, with seven meters put in series with ten lamps. The readings showed a variation of only one and one-half cents in the amount of the bill charged, while four of them were alike to a cent. The advantage of such accuracy is manifest not only to the illuminating company, but must also be satisfactory to the most exacting customer. One of our most experienced and successful managers testifies that in the use of about two hundred meters he found the poorest record to be very close, and sums up his experience by declaring that "without the meter they would be swamped."

But the only real criterion is that of practical success.

In order to discover what the practical men in the busines think of the meter, a circular was recently addressed to the 26 stations in the country now operating the meter system, asking for their experience and opinions. To this we have up to this time received 22 replies. That you may judge of the convictions which they express I will read the more important queries, and summarize the answers.

Question :—"Have you used meters from the starting of your station?"

Answers :—"Yes, 18 ; No, 5."

Question:—"From your experience what reasons would you quote for a change from the contract to the meter system?"

All replies to this question indicate the unanimity of the opinion that the meter is far preferable. Some of the expressions are as follows :—

(1) "There is no argument about lamp breakage. It is square dealing on both sides."

(2) "They are always superior, even to the best contract."

(3) "Less unnecessary burning ; income in more fixed ratio to expenses. Customers are able to regulate their light bills. An accurate basis instead of guess work, to estimate schedule price. Life of lamps should be much longer by use of meter, by the stopping of unnecessary burning."

(4) "We should take in a great deal more money than we do now."

(5) "There are a few exceptional cases where we are getting a little more out of contracts than we would from a meter, but as we run by night only, this difference is made possible. I refer to early closing stores. If we ran by day these would use light by day on contract, while they would rarely do so if the current were measured. I find generally that dwellings on contract are constantly fully illuminated, but the day a meter is put in they find one lamp generally suffices. I believe our income would be slightly larger if everything were on contract but our expenses would be out of all proportion. Immediately after taking charge of this station I looked up the last ten-minute record made by outgoing current, dated December 23d and 24th. It is possibly a little unfair to take a day or night so near Christmas, as more light is used at that time than at any other. The nearest aggregate I could get out of 75 tests in money value was, at one cent per hour per ten candle lamp (and the company charged at that time 1¼ cents per hour), and after deducting station and street lighting, $2,868.90, while the income of the company for that month from all sources was about $1,100. Of course during the winter months the contract consumer gets more than he pays for, and is reckless in the summer, because he thinks he gets less than he pays for."

(6) "By all means were I to build and manage a new station I would start it on a meter basis, and carry it as far as possible."

(7) "Our object was to decrease the unpaid consumption and increase the revenue."

(8) "We believe, from our experience, we can supply more on meters with the same power and get a better return from current used."

(9) "The contract gives a regular income to the company throughout the year, nevertheless in a majority of cases it is a system of robbery ; electricity should be sold like merchandise—by measurement."

(10) "The principal reason for a change to a meter system was the impossibility of making contracts which were fair to the company. Customers will burn more light than they contract for, and though under a contract system it may be easier to collect bills, at the same time the income per lamp hour will not average much more than half that of the meter system."

(11) "It prevents people from consuming an excess of current, thus unnecessarily overloading the station."

(12) "Under a contract consumers abuse the use of the light, which abuse while doing the customer no benefit, (the light not being necessarily used), increases the cost of operating and lamp breakage to the company very largely. In other words, you cannot trust customers to cut their own cloth."

(13) "More satisfactory to the consumer if he is economical."

(14) "Maximum revenue for maximum power."

(15) "Consumers can gauge the quantity of light for which they pay, to suit the business requirements."

Question :—"Do you keep meters on contract installations for your own information?" Some of the replies are as follows :—

"We have, and find a contract consumer is using about double what he pays for. Some customers have left us on this account but almost always return."

"Yes ; on all motors also.

"We run them in this way at intervals for our own satisfaction."

One of the largest of the stations keeps a meter on each contract motor.

Question:—"Have you evidence of any serious error aside from accidents? If so, please state explicitly what it is."

Eight stations, embracing the large ones at New Orleans, Rochester, La Crosse, Cincinnati and New York, reply to this question—"No."

One of the most experienced station managers makes this reply.

"We have none. In my judgment the greatest amount of complaints come from places where a notable lack of care is shown in properly preparing plates, weighing and handling ; also where leaks and grounds are most numerous. The meter has in past years located many faults for me."

Question :—"Is the feeling of your customers generally one of confidence in the accuracy of the Edison meter?"

Most of the stations reply without other remark than emphatically "Yes." Some of the answers are worthy of being quoted literally.

"In some cases our customers keep count of the hours. All such customers say the meters are correct."

"Remarkably few objections by consumers to the results obtained."

"The general feeling is one of confidence."

"The confidence is fully as great as in gas meters ; we have no difficulties on this account."

"Complaints are very few from consumers."

"The meter to our customers is a blank. While we can persuade them that the meter is correct if properly manipulated, it becomes a matter of confidence in the meter man."

"One month ago one of my customers began keeping a record of the hours his lamps were burning. When his bill was presented it was four cents in his favor ; so it is with a great many. The meter has given us good results."

"This question is rather a difficult one to answer. I have no doubt that the majority of our customers if they were asked the question would say that they did not believe in a meter. This is not due in a great many cases to any inaccuracy they have ever discovered, but merely to the general idea that meters are not worth anything, judged by the gas and water meter standards. We have had a number of customers test our meters, and in addition to this have given us strong letters of recommendation, and I have never seen the test where we had to recede from our position that the meter was correct."

"They have as much confidence in the Edison meter as in the gas meter, and probably a little more."

"Those consumers who keep a careful lamp account for a few months have faith in the meter."

Question :—"From the results of your experience with the meter system do you feel that you can endorse our recommendation to new companies that they adopt it as the most satisfactory method of serving the public?"

"Yes. I have already advised several new companies to adopt it. Contracts are bad. They soon get the best of you."

"We believe that it is the only way to sell light. We only have contracts to satisfy certain customers."

"Yes, where practicable, which however is not always the case in starting stations in small towns."

"I do not believe in the contract basis at all. I feel

that the meter is a good thing, and particularly because my economical customers never raise any questions and we never have any trouble with them."

"Yes, most decidedly for large stations. The desirability of putting in a meter system depends on the size of the plant. I do not consider that any plant of over 500 lights can afford to get along without it."

"Yes, but would offer contracts as well. Give them what they want, and if one does not prove satisfactory, give them something else."

THE EDISON ELECTRIC ILLUMINATING CO. OF NEW YORK,
16 and 18 Broad Street.

Spencer Trask, President.
John I. Beggs, Vice-President and General Manager.
J. B. Skehan, Secretary and Treasurer.

NEW YORK, December 27th, 1887.

E. H. JOHNSON, ESQ.,
President Edison Electric Light Co.,

Dear Sir—Replying to your inquiry as to the accuracy and degree of reliance placed upon the Edison meter in the commercial transactions between this company and its customers, it affords me pleasure to state that our experience has established confidence in the meter, not only on our part, but also on the part of our customers, in consideration of which I offer you the following facts:

The Pearl street station was started September 4th, 1882, and, with the exception of but two hours during the first year, has continued uninterruptedly to date.

The station is at present supplying current for 15,000 incandescent lamps and 150 h. p. of Sprague electric motors to 647 customers through a like number of meters.

Our bills are paid cheerfully with but an occasional exception, in which instances a verification of the meter is had, and the customer thereby thoroughly convinced of its accuracy.

Repeated tests of the meter, comparative and otherwise, made by ourselves, show a maximum variation of not greater than 2 per cent. and a variation from accuracy of not more than 1 per cent. These tests, combined with the practical results of five years' actual use of several hundred meters, have demonstrated conclusively to the company and its customers the efficacy of the apparatus for the purpose intended.

Yours truly,
THE EDISON ELECTRIC ILLUMINATING CO. OF NEW YORK,
By JOHN I. BEGGS,
Vice-President and General Manager.

The following, it is hardly necessary to say, was penned in the bracing air of the Rocky Mountains, and has the ring of Western enterprise:—

"I can endorse the meter for two reasons. It is the friend of the poor man as well as the company for the following reasons: It gets action on the horny-handed son of toil this way. Our contract price for lighting houses for five lights is $4.25 per month or $51.00 a year. Now there are lots of customers who cannot afford to pay that but can afford to have five lights installed and use the meter, which will probably not average over $2.50 per month or $30.00 for the year. At the same time, if they should contract for $4.25 per month, and then run till 12 o'clock for a month, they would consume $13.50 per month (if measured by the meter), but we would only get $4.25. If all did this our load would overrun our capacity, but thanks to the little box—she holds her down. It produces the same effect with business houses. Our contract price with this class is $1.50 per month (all my figures are based on 16-candle lamps). Houses having 25 lights would be $37.50 monthly; by meter we would realize $29.10 average for year, our lighting being 6 till 9. You see we get $29.10 for 3 hours light, while with contract they could burn till 12 for $37.50 or six hours light. The meter holds the load down for families when they use only one or two lights a night, but if contracted they would 'turn her loose, Murphy,' in order to play even. It is our experience that the people always manifest a desire to play even with a light company if possible, and if they can't get action one way they will another.

"Our meters here are a great deal of labor owing to the number we have in use, but still we can't get along without them and really think they are reliable if conditions are equal. My tests here have been very flattering, have had them within 1-10 of one per cent. of bill and the highest out was 2 5-8 per cent. high.

"For customers using a large amount of light it is cheaper for them to contract here, but for small customers the meter is the correct thing, and with us produces satisfaction and good results among the customers. In the summer bills are small, but the winter months balance them and run higher; when expenses increase, so do the meter bills, but with contracts it would be the same."

The reports referred to, represent the following aggregates and averages:—

Total number of lamps of all powers in 23 stations		117,501
" " " " on meters		87,856
" " " " on contracts		29,305
" " " motors		350
" horse-power of motors		1,000
" number of meters of all capacities		5,187
" " " two-wire meters		4,531
" " " three-wire meters		660
Average number of lamps per station, meters and con'cts		5,109
" " " " on meters, 23 stations		3,820
" " " " on contracts, 20 stations		1,465
" horse-power of motors		8
" number of meters per station		226
" " " lamps per meter		17
Total cost of meter operation, 16 stations	$16,235.00	
Average annual cost of operation per meter	4.03	
" " " " " " lamp	0.22	

It is also of interest to note that of the twenty-three stations equipped with meters for the measurement of seventy-five per cent. of their entire lamp capacity, and relying upon these meters for the amounts of their bills to consumers, four are earning upwards of fifteen per cent. on their capital stock; three others between ten and fifteen per cent.; three others between eight and ten per cent., and eight more between five and eight per cent. on their capital stock. Others have been operating for too short a time to yield definite results.

The following extract from a letter from Mr. J. W. Lieb, Milan, Italy, written under date of November 2d, 1888, demonstrates clearly how satisfactory the action of the meter may be made, even when the urgent cares of a rapidly growing business, forbid the one engineer of the station who is thoroughly informed on this subject, from giving the details of its operation any considerable personal attention. Mr. Lieb has labored under the additional disadvantage of being at a great distance from the birthplace of the system, and the scenes of its widest usefulness.

"We have at present actually in use in Milan some 360 meters of various types (all Edison meters), the smallest for 350 ampere-hours per month, and the largest 30,000 ampere-hours with a respective maximum capacity from four to 400 amperes.

"All the current from the mains is paid for by the ampere-hour according to the sliding scale of charges herein enclosed.

"The temperature to which the meters are exposed varies between 5 degrees centigrade and 35 degrees centigrade. We have never had occasion to apply thermostats to the meters. The results of our experiments and our general experience with the meter have given us confidence that, if carefully treated, its indications are fairly reliable, the maximum error (low reading), occurring with light loads.

"While we have some consumers whose consumption of current is comparatively uniform throughout the year, the majority (among whom many apartments) consume little or no current during the summer months, some consumers closing their apartments and making the meters inaccessible for four or five months.

"Our consumers are as a rule very close, a number keeping careful account of their lamp hours (ampere-hours), from month to month, the larger ones having clerks specially delegated for that purpose.

"This fact, coupled with the unfavorable conditions of

supply above noted, makes it necessary to apply all precautions to avoid contestations, and I am glad to say we have been fairly successful in meeting the difficulties.

"We keep a careful half-hourly register of the indications of the main station ammeters and the feeder ammeters and find them to agree with each other, and their sums with the ampere-hours given monthly by the meters within a small percentage of error which we have observed is a maximum during the summer months, the sum of the meter indications being slightly low."

Such abuses of the contract system as are shown by the foregoing expressions are so manifest to many contract stations from which we have asked for no letters, that some of them are already changing to a meter basis, and it is evidently only a matter of a short time when others will be compelled to do likewise.

At every meeting of the Association of Edison Illuminating Companies there has been a full and impartial discussion of the relative merits of the two methods. The result may be briefly and forcibly summed up in the following, unanimously passed at the meeting of the Association held at Chicago, Illinois, February 9th, 1888:—

"*Resolved*, That after a full discussion of the relative merits of the meter and contract systems in the numerous meetings of this Association, that it is the sense of the Association that the Edison meter is accurate, that the system is not too expensive for stations above 1,000 lights, and that the best financial results are invariably secured in a station selling by meter."

Recent improvements.—Nearly a year ago a series of exhaustive tests was undertaken at the laboratory of Mr. Edison, to determine whether in the light of years of experience since the initial experiments upon which the first methods were based, advantageous changes could be made.

The first result of these tests was the perfection of the general details of the three-wire meter, then being offered to the Edison stations. The present form of connecting spring clip was at once introduced. A diagonal arrangement of terminals, making it easy to connect from either side or from below, followed after. Then the production of pure chemicals by the Edison laboratory, and the elimination of the error due to oxidation (already referred to) by proper treatment of the solution.

At a meeting of the Standardizing Bureau, held December 17, 1888, it was voted to authorize the discontinuance of the two largest sizes of plates (40 and 80 amperes), and use in their places the 20 ampere plate with a proper change in the compensating spool in each case. It was found perfectly feasible to measure the shunt resistances and weigh the plates more accurately than heretofore, thereby effecting a substantial saving in cost and care of large plates. As an illustration, a 200-light plate only needs to be weighed to one-sixteenth of the exactness in units of what is necessary in a 12-light plate to secure the same percentage of accuracy.

It was also decided to authorize the use of one bottle in place of two for the three smaller capacities, which, as appears by the average figures given, constitute a large majority of the total number in use. This will probably be followed by a change in all sizes as soon as confidence in the feasibility of this plan becomes general. One-bottle meters for two-wire uses, and two-bottle meters for three-wire, will therefore be immediately produced.

These important changes, which it will be observed simply follow as a natural result of the confidence established by experience, will probably be supplemented by others, none of which will, however, modify any essential features of practice, but simply apply processes which add nothing to the expense but tend to eliminate the already small sources of error. Among those indicated as likely to be recommended are a reduction in the size and change in the form of the bottles and method of closing; a slight change in the specific gravity of the solution, and a modification of the treatment of the plates by which the active surfaces shall be limited to those placed directly opposite each other in the cell.

These minor changes will aid still farther toward the result which Mr. A. E. Kennelly (under whose personal supervision the present tests are being made) predicted in a recent lecture would be realized, namely: that "The Edison electrolytic meter will in the future be recognized as the simplest and most accurate apparatus of its kind in commercial use."

An interesting application of this Edison meter principle has been made in England, and is described as follows in the *Electrician* article already quoted, relative to a multiple-series installation at Brighton:—

"The objections to the electrolytic method are absent, when it is employed in connection with a constant current distribution. In the first place, we have now to measure the 'volt-hours' across the terminals of the house connections, so that the meter is a shunt to the whole installation. By placing a high resistance in circuit with the meter in order to reduce the current in the shunt circuit, no error is introduced. Secondly, by integrating the E. M. F. and assuming constant current, we are introducing no non-existent factor; in fact, the current at Brighton is actually maintained constant within one per cent."

This suggests interesting possibilities in measurement of energy supplied to customers of series circuit systems.

I have not taken your time this evening to prove by aggregation of testimony simply that a meter basis is the proper principle, or that the electrical fraternity needs it and should be educated to its use. This is self-evident. My aim is to show by the incontestable logic of facts that it is entirely practical and economical to accomplish all that is required by a method which is widely applied, and to emphasize by varied but singularly harmonious quotations from the experience of men who are by its help earning dividends, the result of "Six Years' Practical Experience with the Edison Chemical Meter," which is the topic of my paper.

A SKETCH OF THE HISTORY, DEVELOPMENT AND PRACTICAL APPLICATIONS OF THE ELECTRICAL CONDENSER.

BY WM. MAVER, JR.

PART I.

IT can safely be said, I think, that while there may be instruments of more importance in the applications of electricity than the condenser, there is none which has more varied and interesting uses in practical as well as experimental work than that instrument.

This was particularly brought to my attention during researches into the history of the condenser and its applications in telegraphy in connection with an important patent suit brought a few years ago by the Western Union Telegraph Company against the Baltimore and Ohio Telegraph Company, to restrain the latter company from using the condenser as a "static compensator" in duplex telegraphy.

A number of items concerning the history and applications of the condenser I noted at the time for future reference, and while I do not pretend that, as elaborated in this article, those notes will exhaust the subject, yet I venture to hope that they may be read with more or less interest by some whose duties or studies have not made them acquainted with the history and various applications of the condenser.

It will be apparent, from a comparison of the following quotations and illustrations from the works of prominent writers on electrical subjects at different periods, that the apparatus generally known to-day as the condenser is quite a different instrument, both as regards its form and function, from that to which the same name was originally applied.

Clark and Sabine's Electrical Tables and Formulæ, 1871.—"Accumulators, or as they are commonly called, condensers, are used for comparing the electrostatic capacities of cables, the electromotive force of batteries, for joint testing, and for preventing earth currents in submerged cables."

Preece and Silverwright's Telegraphy, 1876.—"A condenser or accumulator is a term applied to an apparatus composed of alternate layers of tin-foil and paraffined paper (or mica) so arranged as to form a flat Leyden jar of large surface, and constructed to give us whatever capacity we require."

Kempe's Electrical Testing, 1887.—"A condenser is merely a Leyden jar exposing a large surface within a small space."

Stewart and Gee, Electricity and Magnetism, 1887.—"A condenser for the purpose of this chapter may be considered as consisting of sheets of an insulating material, arranged alternately with sheets of a conducting material, &c."

S. P. Thompson's Electricity and Magnetism, 1881.—"Their general form (microfarad condensers) is shown in figure 1, which represents a ⅓ microfarad condenser."

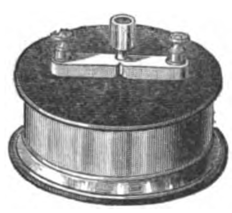

FIG. 1.

Prescott's Electricity and the Electric Telegraph, 1888.—"The condenser is an apparatus by means of which a large quantity of electricity can be gathered on a small surface.

Cavallo, in his Philosophy, 1803, thus describes a condenser and its action: "If there be a source of electricity which, when communicated to an electrometer, is too weak to affect it, let an ample insulated plate communicate with the body which furnishes the weak electricity, and the plate so situated will acquire a considerable quantity which, whilst this plate is opposed to the other, will not affect the electrometer; but if afterwards the receiving plate be removed from the vicinity of the other plate, its capacity for containing electricity will be diminished, and of course the absorbed electricity will appear much stronger upon its surface," etc. Such a receiving plate was called a *condenser* by Volta. Dr. Lardner observes concerning the condenser: "In the estimation of small quantities of electricity it is analogous to the microscope in the examination of visible objects, and it stands in the same relation to the electroscope as the compound microscope holds to the micrometer screw and vernier in astronomical instruments."

Noad's Manual of Electricity, 1855.—part i., p. 61—Referring to condensers,—"instruments contrived for the purpose of rendering evident very minute traces of electricity.

Sir Wm. Snow Harris, Frictional Electricity, 1867, p. 90—"The object of the condenser is to render sensible to the electroscope minute quantities of electricity, which, without its aid, would be inappreciable."

The original condenser as used by Volta was constructed as represented in figure 2, and is thus described in Noad's Manual of Electricity, 1855. "It consists of two circular metallic discs, the surfaces of which were covered with a thin and uniform coating of amber varnish; the lower disc B was supported on a metallic stand D, the upper disc, A, called the collector, was provided with an insulating handle, C, and a short wire terminating in a metallic ball, E. The body, the electricity of which was to be investigated, was brought into contact with E, the electricity thus communicated to A acting by induction, through the thin non-conductor on B, confined the electricity of the opposite kind repelling its similar electricity; at the same time B, being in perfect electrical communication with the earth, had a constant supply of neutral electricity conveyed to it

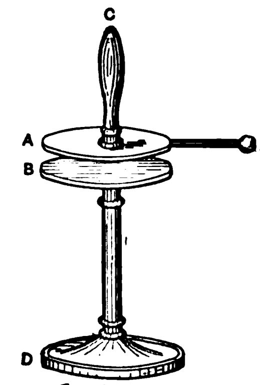

FIG. 2.

which in its turn underwent a similar decomposition. This process lasted until the *condenser* had received the full charge answering to its surface. The collector A being suddenly raised by its glass handle, taking care to keep it parallel to its base, the electricity accumulated upon it could be transferred to an electroscope for examination."

It was usual, however, to attach the condenser directly to the gold leaf electroscope, as in figure 3. In this case one of the plates of the condenser is mounted on a joint that is movable at the bottom so that it may be moved to and away from the other as shown in the figure. "By the induction of electricity on the surface of the movable disc several times and by its reaction on the electrometer (electroscope) an accumulation of the electric force is affected by which means the presence of otherwise inappreciably small quantities of electricity is detected."

The Franklin plates as described in Franklin's letters, and alluded to by Priestly as a modified Leyden jar, in the quotation below, constitute perhaps the earliest description of an instrument to which the modern condenser most nearly corresponds.

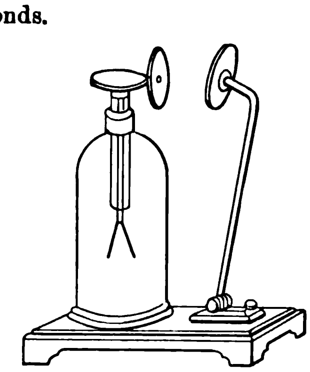

FIG. 3.

"Dr. Franklin constructed an electrical battery consisting of 11 panes of large sash glass coated on each side and so connected that charging one of them would charge them all. Then having a contrivance to bring the giving sides in contact with one wire, and all the receiving sides with another, he united the force of all the plates and discharged them all at once."

Akin to this also is the Franklin "pane," shown in figure 4, which consisted of a pane of glass coated on both sides and supplied with suitable connections for charging and discharging.

The invention of the electrical condenser as defined by Cavallo, Noad and Harris, is attributed by Noad, Bakewell, S. P. Thompson, and others, to Aepinus or to Aepinus and Wilcke. But Noad credits Volta with having brought it into the service of electrical science.

Sir Wm. Snow Harris, however, in the preface to "Frictional Electricity" takes up the defense of Volta as the inventor of that instrument, and incidentally states that "M. Biot in his life of Volta seeks continually to disparage the quality of mind of that truly great man, upon the ground that his researches and discoveries had not a rigor-

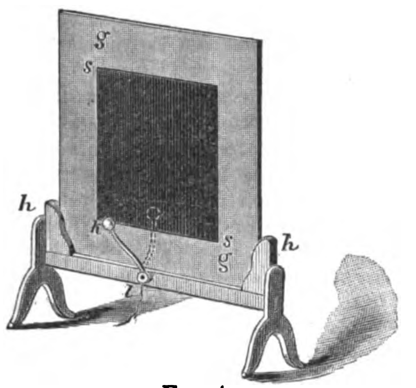

FIG. 4.

ous mathematical basis, etc., and is hence led, although constrained to admit the vast genius of Volta, to refer nearly all Volta effected to previous principles mathematically deduced by Aepinus, although no one ever heard of the condenser or the electrophorus before Volta. Still we are informed that the principles were foreseen and their theory given twenty years before by Aepinus."

The evolution of the Aepinus induction plates into the form of apparatus known to-day almost universally as the electrical condenser had begun to take shape prior to 1840, but the manner in which the instrument is referred to by different writers seems to indicate that it had not yet received a definite name and further that it was classed neither with the Leyden jar nor with the Volta condenser. Indeed it may be noticed that both prior and subsequent to 1840 various writers carefully avoid applying either the term condenser or Leyden jar to the instrument, and instead refer to it as a "reservoir," "extended, insulated, metallic surface, etc." For example, Sturgeon in his Annals of Electricity, 1836, refers to what has since been termed by others, a card-board condenser, as follows: "These boards answer exceedingly well as a *reservoir* for low intensities. They may be coated to within an inch of the edge all round and placed upon their edges either on a piece of glass or on a board properly prepared and arranged to any extent required, like the plates of a voltaic battery, but when considerable intensity is desired it is better to use thin glass."

Again referring to an arrangement, which he says is a modification of his card-board reservoir, used in connection with an electro-magnetic machine of Rainey's in the same year, Sturgeon writes, "about three yards of varnished silk cloth were coated on both sides by broad strips of tin-foil and coiled around a cylindrical nucleus of wood, an intervening ply of silk preventing the two coatings from touching."

Again, in Silliman's Journal, 1838, Professor Page, in describing a series of very striking results from the secondary current of a new magneto-electric machine, states, "It caused the gold leaves of the electroscope to diverge strongly without the aid of a Leyden jar or extended insulated metallic surface."

Still later, in Bakewell's Manual of Electricity, edition 1857, is found the following: "At the recommendation of M. Fizeau a large conducting surface consisting of several square feet of tin-foil pasted on each side of varnished silk, is connected with each of the wires through which the voltaic current is passed."

In 1854 C. F. Varley, in British patent No. 2,555, for "Improving and applying Dynamic Electricity," describes a form of condenser practically similar in construction to those in use to-day, which he termed "induction plates" and describes as follows, with a diagram here reproduced as figure 5, (which is virtually the present conventional manner of graphically representing the condenser.) "Figure 5 is an end view of a series of induction plates, which are to be laid close to each other, but here they are separated to show them. A pile of these form a Leyden battery. They may be put together in various ways * * * the sheets (induction plates) are of tin or other metallic foil (separated by) sheets of oiled silk, gutta-percha or other non-conducting surface * * * the gutta-percha (or insulating) sheet being larger in every way (than the metallic foil) prevents the opposite foils touching each other."

In his British patent 1,509, 1859, Mr. C. F. Varley still adheres to the term "induction plates" in referring to condensers.

Of course it is not meant to imply that these writers were not aware that the electrical law or laws governing the action of the Leyden jar, Franklin's plate, etc., were similar to those governing the Volta condenser, but rather to show that they were so familiar with the specific function of the condenser as then understood that the use of that term would not have properly defined, to their minds, the new arrangement and construction of the plates to which they had reference.

Some subsequent writers, however, perhaps losing sight of the earlier specific function of the condenser, have had no hesitation in defining the term; as, for instance, in Beechey's Electro Telegraphy, page 95, it is said, "* * * This is the condenser, the original type of which is known as the Leyden jar, which was a glass jar with a coating of tin-foil pasted carefully inside and out," etc.

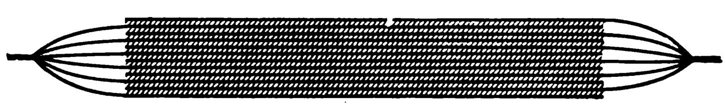

FIG 5.

In Gordon's Electricity and Magnetism, vol. 1, page 67, it is stated, "A Leyden jar is sometimes called a condenser because it was formerly supposed that the strong electrical effects observed were due to the condensation of an electrical fluid or fluids."

The term condenser as applied to the Leyden jar has been more frequently used within the past twenty years than, so far as I have been able to discover, at the time when its effects were supposed to be due to the condensation of an electrical fluid or fluids.

The changed meaning of the term "condenser" has been thus briefly traced as another instance of the gradual manner in which a name or term applied to an instrument having originally a specific function may be transferred to an instrument not necessarily having that function, and the original function be practically lost sight of. In this particular case the original object or use of the electrical condenser is already omitted from some modern text books of electricity.

There is but little doubt that the term condenser will now adhere to the instrument at present bearing that title. There was at one time a disposition to designate it *accumulator*, but that word has since been applied almost exclusively to storage batteries.

The meagre descriptions of the "induction plates" of Sturgeon and of Fizeau, already quoted, show a very crude form of condenser. These were vastly improved upon by Mr. C. F. Varley, yet we find him saying in his British

patent No. 206, 1860, "Induction plates being bulky and expensive I use in most instances plates or wires of platina. Two of these plates are placed in each cell containing sulphuric acid and water, a number of these cells are connected together like a voltaic battery, consisting of plates of the same metal, instead of dissimilar metals; when so many of these are used that the battery cannot decompose the water they become induction plates of great inductive capacity, and a few inches of surface give as great inductive capacity as many miles of submarine cable."

Again, in patent No. 3,453, 1862, Mr. Varley states, "To save expense the resistance of this test circuit may be increased say 10-fold when the induction plates are reduced in size in like proportion, etc. * * * Having found difficulty in constructing large induction plates with certainty I have been led to try, amongst many other insulators, paraffine, and I find that paper saturated with it forms an excellent insulator for this purpose."

Even in 1867, it would appear from a report of a committee of the British Association on the determination of a unit of capacity (B. A. proceedings for that year) that not much advance had been made in the construction of condensers. This report is of so much interest as detailing the state of the art as regards condensers at that time that it is given here almost in full.

"The determination of a unit of capacity has occupied the sub-committee during the past two years. Very considerable difficulties have been encountered and are not yet wholly overcome. The methods by which electro-static and electro-magnetic units can be determined are sufficiently simple in theory, but they assume that the condensers or Leyden jars compared have a definite capacity, and that with a given E. M. F. between the surfaces a definite quantity of electricity will be contained in the jar or condenser. This is very far from true with condensers of the ordinary form. Whether the dielectric separating the plates be glass, mica, gutta-percha, paraffine, ebonite, or any other known solid insulator, an absorption of electricity takes place. The longer the plates are charged the more electricity the condenser will contain, and conversely it will continue to discharge itself for a long period after the inner and outer armatures have been joined. With some of the best insulation the effect will continue for hours if not days. Condensers made with these solid dielectrics have therefore no definite measurable capacities. This capacity will differ according to the time during which they have been charged, and it may vary also with extreme variation in the electromotive forces employed, although this latter change has not been detected when the differences of potential are such as between one Daniell cell and two hundred. Only gaseous dielectrics appear free from this embarrassing peculiarity, called absorption, polarization or residual charge. One object of the sub-committee has been to construct condensers in which air alone separates the induction plates. But new difficulties arose in carrying this idea into practice. Some support for each plate was necessary, and then leakage occurred from one plate to another over the surface of any small insulating supports employed, such as glass balls or vulcanite stems. It was possible by great care in drying the air occasionally to make condensers of this type, which would remain insulated for a short time or even for some months; but long experience has shown that an artificially dried atmosphere cannot be conveniently maintained in any instrument which is not hermetically sealed. Dust also accumulated between the plates of the trial condensers; this altered their capacity and increased the leakage from plate to plate. Even a single filament of dust by springing up and down between the two electrified surfaces would occasionally bring them to the same potential with great rapidity, neutralizing the charge. Moreover, a condenser of this type could not be taken to pieces and cleaned, for no mechanical contrivance would insure that the parts after cleaning would return to their original position so exactly as to constitute a condenser of the same capacity before and after cleaning. It is therefore clear that an air condenser can only be constructed in a hermetically sealed can containing an artificially dried atmosphere; and even with those conditions, excluding the graduated and adjustable condensers which were first tried, the air condenser is not easily constructed. For large capacities which are alone useful in connection with practical telegraphy the plates require to be so numerous and large as to make the expense great and the bulk very inconvenient.

"But meanwhile practical men have introduced condensers of a more convenient form, overlooking the disadvantages which they all possess of ill-defined capacity. These condensers consist of sheets of tin-foil separated by paraffine and paper, a preparation of gutta-percha, or mica, three plans adopted by Mr. Varley, Mr. Willoughby Smith and Mr. Clark, respectively.

"Mr. Jenkin has adjusted a mica condenser approximately equal to 10^{-14} absolute electro-magnetic units. The capacity of this condenser is assumed as that which it possesses after electrification for one minute, and is measured by the discharge through a galvanometer in manner usually practiced when testing the charge of a submarine cable. * * * While, therefore, the new provisional unit of capacity has no claims to a high scientific accuracy, it will supply a practical want, and introduce a unit based on the principles adopted by the committee, in place of the random measures supplied by a knot of Persian Gulf or Atlantic cable."

This knot of cable as a unit of capacity, although perhaps somewhat crude, was a decided advance in what may be called the unit of capacity of a Leyden jar in the early days of the history of that instrument, which was determined by the length of wire which its discharge was able to fuse. It appears (Nicholson's *Journal of Natural Philosophy*) that the highest charge of a battery belonging to Dr. Van Marum, and containing 135 square feet of coated surface, could just fuse 180 inches of iron wire $\frac{1}{150}$ of an inch in diameter, or six inches of iron wire $\frac{1}{40}$ of an inch in diameter. Another battery belonging to the same person, and containing 225 square feet of coated surface, could melt, with its highest charge, 300 inches of the first mentioned wire, or 10 inches of the last. Also, the highest charge of a third battery, which contained 550 square feet of coated surface, could fuse 25 inches of the latter wire." Cavallo, on this point, says: "The force which is required to melt wires of the same metal must be greater or less, according to the length and thickness of the wire; but it is far from bearing any direct proportion to the quantity of metal. For if a wire of a certain length and diameter be barely melted by a large battery (Leyden jars), a wire of equal length and twice the substance cannot perhaps be melted by less than ten such batteries," which is interesting as showing that Professor Cavallo was here in a fair way to discover the actual heating action of the current, which, as is now so well known, varies as $C^2 R$.

Within the last few years there has been a decided improvement in the construction of condensers both as regards stability of the insulation and the retention of charge, two qualities that go together. Standard condensers of one-third microfarad capacity, made in Europe, have shown an insulation resistance of over 20,000 megohms, and much higher insulation can doubtless be furnished. Standard condensers of similar capacity made in this country have shown a resistance of over 28,000 megohms, and a still higher insulation can be obtained if desired. But for ordinary testing and experimental purposes this insulation is found sufficient.

Tests made of paraffine paper condensers designed for practical application in telegraphy and particular electric lighting purposes, have demonstrated the capability of such condensers to withstand being placed between the poles of a 1,000 volt alternating current dynamo for twenty-four hours without injury, and hundreds of similar instruments are in use in this country, in telegraphy and telephony,

under conditions which virtually subject them to the strain of lightning arresters, also without injury. These condensers are of American manufacture, and in view of the fact that at least one system of telegraphy in Europe has been in some instances abandoned, partly, at least, on account of difficulties thrown in by the failure, from lightning, of the condensers employed in its operation, while another system in this country has been more or less seriously injured by the use of an inferior quality of condensers, and as others may be deterred from developing apparatus or systems requiring the employment of this useful instrument on the assumption that reliable condensers cannot be manufactured at commercial rates, no apology, need, I think, be offered for introducing the foregoing information as to the high merit of American condensers.

PRACTICAL NOTES CONCERNING THE CONSTRUCTION, USE AND MANAGEMENT OF STORAGE BATTERIES.[1]

BY A. RECKENZAUN.

(Concluded from page 480, volume vii.)

WITH this issue we bring the series of "Notes" to a conclusion. The subject has by no means been exhausted —indeed, it has received but a general treatment; and the original object—viz., that of publishing a few important experiments and observations—had to be kept in view. Great strides have been made in the manufacture of storage batteries since the commencement of these "Notes," but the principles enunciated therein from time to time still hold good within the limits of their treatment. By far the greatest portion of these articles related to results of experiments made by the author, and these were limited to storage batteries of the most popular kind, composed of lead and oxides of lead. Up to a recent date these were the only commercially successful ones. Mr. Howell's new storage battery, which is now being introduced by Messrs. Crompton & Co., appears full of promise, but little is as yet known concerning its general properties. Mr. Howell's plates consist of spongy lead slabs produced by a peculiar process, the essential feature of which is kept secret. Contrary to popular notions, these plates are made to give considerable storage capacity, when compared with their weight, and the process of "forming" is said to occupy not more than two or three weeks, and without frequent reversals, differing therefore from the ordinary metallic lead or Planté types. Mr. Howell informed the author that a sample cell, containing 17 plates, weighing together 35 pounds, and each plate measuring 6 by 6 inches, gave a capacity of 185 ampere hours, at an average rate of 30 amperes, and that for the space of 10 minutes a discharge rate of 600 amperes had been maintained. According to this statement we have the very interesting fact that spongy lead plates can be made to yield 5.28 ampere hours per pound of metal at a considerable rate of discharge. Although no mention is made as to the durability and cost of these plates, we are assured that these items will be found satisfactory.

Copper as an element in secondary batteries.—About seven years ago Mr. Sutton invented a storage battery composed of a lead plate to be peroxidized, and a copper plate to be alternately dissolved and deposited from the solution of sulphate of copper. This battery has not found any industrial application for obvious reasons: the action in a cell with metallic solutions is not constant, the layer of liquid in contact with the metal changes, and eventually refuses to act. In charging, soon after the first action there is no metallic salt present to decompose, but merely acid, which gives off gas, and then the metal deposit becomes non-adherent. In discharging, the metal salt forms too rapidly to dissolve and crystallizes on the plate. These crystals form "trees," and eventually short-circuit the plates. It is for this reason, also, that the zinc-lead accumulator remains still within the precincts of the laboratory.

Messrs. Commelin, Desmazures and Bailhache in May, 1887, brought out a new accumulator, in which copper plays an important part. For the description of this we are indebted to M. Reynier's work, "L'accumulateur voltaïque."

The positive electrodes of this battery are made of porous plates, obtained from finely-divided copper under a pressure of 600 kilogrammes per square centimeter. Electrolytically reduced copper, free from oxides, is used.

The negative electrodes are of tinned iron plates; these are amalgamated. The tin has to hold the mercury which does not adhere to the bare iron. The receptacle is made of tinned sheet steel; the negative electrode rests at the bottom of the box, and it is in contact with it. The electrolyte consists of water, zinc and potash in the following proportions:—

Water	1,000
Zinc	144.67
Potash in solution	209.82
" free	313.72

The positive electrodes are enveloped in parchment paper, and insulated from the negatives by means of glass rods. The parchment is stitched on, and although the seam is not watertight at first, it becomes so through the action of the liquid, which causes the paper to stick fast. The parchment undergoes a change through the action of the alkali; it swells and becomes brittle, but it appears to hold on a considerable time without breaking, if no mechanical disturbance takes place.

Without the parchment the action is irregular; the oxydation of the positive electrode is not complete, and deposits of zinc are mixed with copper; hence want of adherence and local actions or short-circuits through the formation of "trees," as in other batteries where metallic deposition takes place. These envelopes, therefore, play a very important part.

M. Finot, the chemist who examined this invention, gives the reactions during the discharge thus:—

$$\mathrm{Zn + KO, HO, Aq + Cu_2\,O = Zn\,O, KO, Aq + 2\,Cu + HO},$$

but there appears to be a doubt as to whether this is the correct rendering of the equation, and it requires confirmation; curiously, there are hardly two authorities who agree on the subject of chemical reactions in secondary batteries.

M. Finot ventures another theory in the *Bulletin de la Societé Internationale d' Electriciens*, where he states that during the charging of a copper accumulator one observes a curious phenomenon, which tends to show that oxygen does not combine with the copper, but that it may be occluded, and this occlusion may be due to peculiar properties of the porous plates.

When the apparatus is being charged one may observe that from the commencement of charging the level of the liquid rises and continues to rise until the charge is discontinued. On the other hand, during the discharge the reverse takes place; the liquid falls gradually, and does not resume its original level until the battery is entirely discharged. If, says M. Finot, the oxygen did combine with the copper, no rise in the level of the liquid would manifest itself until all the copper had entered into combination. Thus the oxygen fills the pores of the plates, displaces the liquid, and causes the increase in volume.

During the discharge again, oxygen should disappear immediately, and the liquid resume its normal level a few minutes after closing the circuit, but this is not actually the case.

M. Reynier thinks that these observations do not appear sufficient to demonstrate that occlusion of oxygen takes place in the positive plates, and he asks whether the rise of

1. From the *Telegraphic Journal and Electrical Review* (London).

level in the liquid is not due to changes of volume in the plates, one of which is oxydized and the other covered with zinc? In order to decide this question the densities of the liquid as well as of the positive plates should be ascertained after the charge; from this may be deduced the total volume of the electrodes and of the liquid. By this method it could easily be determined whether the hypothesis regarding the occlusion of oxygen is correct.

The following weights and dimensions were given by M. Commelin, and they refer to an accumulator which has been constructed for the purpose of propelling a small torpedo boat. The storage capacity of the cell has been ascertained in the laboratory by the inventors :—

Weight of cell in working order	22.046 lbs.
" " 5 positive plates	4.25 "
" " 6 negative "	2.32 "
Height " positive plate	11.02 inches.
Width " " "	4.92 "
Height " negative "	11.81 "
Width " " "	4.92 "
Surface of positive "	54.22 square inches.
" " negative "	58.1 " "
Receptacle, length	5.905 inches.
" width	8.346 "
" height	15.75 "
" weight	2.204 lbs.
Electrolyte (1.55 S. G.) weight	13.224 "
Useful E. M. F.	.75 volt.
Current, charging	15 amperes.
" discharging	48 "
Time of charging	30 hours.
" " discharging	9½ "
Useful capacity	413 ampere hours.
" "	.42 h. p. hour.
Capacity per pound of cell	18.72 ampere hours.
" " "	14.12 watt hours.
Weight per h. p. hour	52.47 lbs.

According to a note (communicated in March, 1888) by M. Krebs to the Académie des Sciences on "L'Essai d'un moteur électrique alimenté par des accumulateur destinés à un bateau sous-marin," the total weight of a Commelin-Desmazures battery to give 1 h. p. hour was found to be 37 kilogrammes, or 81.55 pounds.

This is not a very great advance upon what has been accomplished with certain lead storage batteries, weight for weight. The volume, or dimensions of the copper storage battery are smaller than those made of lead, whilst the efficiency may be alike in both.

With regard to cost one may infer that lead and dilute sulphuric acid must be cheaper than copper and potash; and as to other points of interest we have to ask whether it is necessary to amalgamate the negative plates frequently? How long will the parchment envelope last? What changes take place with the electrolyte in the course of time? No doubt positive plates made of copper are more durable than those made of lead, but the general item, *depreciation*, has yet to be ascertained; if it turns out to be a very small quantity then we may ignore the question of first cost, and then we can congratulate Messrs. Commelin, Desmazures and Bailhache, as well as those in search of a novel storage battery, for an achievement, the beneficial results of which cannot easily be over-estimated.

ABSTRACTS AND EXTRACTS.

ELECTRIC LIGHT FOR MILITARY PURPOSES.

THE following account of experimental firing at night by electric light in Germany is quoted by the *Electrical Review*, of London, from the *Elektrotechnisches Echo*.

WE have just had occasion to witness some nocturnal experiments in rifle shooting by the aid of the electric light in a large garrison, and we may say that all the participators in the trials were exceedingly well satisfied with the result. Last year some similar trials were made by the artillery at Jüterbogk, when the bursting of shells could be distinctly seen at a distance of 2,700 meters. On the present occasion the light was found also to serve well for rifle shooting. The night was dark, a few stars only being visible. At a distance of 400 meters figures and circular discs were fixed as targets. The electrical apparatus was posted 200 meters behind the firing party, and consisted of a wagon carrying a steam engine, a dynamo-electrical machine, and a reflector. The engine was of 18 h. p., and the lamp an arc lamp. The light was perfectly steady without the least flickering. When working with 7 h. p. the machine threw a beam of light to a distance of 4,000 meters, and at that distance pencil writing could be read.

When the trials began we placed ourselves next to the machine, whence we were able to see distinctly the targets, so that it would have been impossible for anyone to have approached within the focus of the light or got near the machine unseen. This would have been the more impossible, as the micrometer action of the reflector enabled the operator to sweep the horizon.

The shooting trials were carried out in the following manner :—The soldiers lay partly in the focus of the light itself so that the sights were sharply illuminated, and these men hit the circular targets at man's height nine times out of ten. Another squad of men lay in darkness firing at the illuminated targets, and their firing was hardly inferior to that of the former.

However, preference must beyond doubt be given to the former method in war, as it is utterly impossible for the enemy to see their opponents when lying in the dazzling light. But if the men lie in darkness the enemy will easily discover them through the flash of their guns.

As regards the electrical apparatus it can only be rendered unserviceable by a bullet hitting the bar to which both carbon points are fixed, as even if a bullet break the glass in the reflector the light will not be affected in the least. The only moment of danger to the apparatus, is when the carbon points are being changed, when, if the force be too great, the apparatus may cease to act. If so, the otherwise intensely white light assumes a violet hue, and in a few seconds the reflector ceases to act, and the disc looks like the moon rising when full, shining with a dull red lustre. At that moment the enemy may destroy the apparatus with the greatest ease by throwing shells at it. It must, therefore, be the chief task of the electrical engineers to take care that the apparatus is kept working steadily and evenly.

THE DURATION OF LIGHTING FLASHES.

IT is well known that the lighting flash, or the spark between the terminals of an influence machine, exists for so short an interval of time as to be beyond measurement by any ordinary means. But notwithstanding the acceptance of this knowledge, the peculiarities of some of the flashes photographed have been supposed to be due to the camera,

or the sensitive plate, being at the time in a state of vibration. To test this line of thought, Mr. James Wimshurst has made a dark slide for his camera, in which is fitted a train of clockwork carrying a disc, upon which is an arrangement for holding the sensitive plate. When all is complete for photographing a flash, the clockwork is wound up, the sensitive plate then rapidly acquires great velocity, which at the maximum reaches 2,500 revolutions per minute, and with the plate rotating at this speed the spark is photographed. The annexed engraving is from a photograph taken under these circumstances; as will be seen, it in no way indicates movement in the sensitive plate, for

the photograph throughout its length is as sharp and as clear as though the plate had been at rest. The experiment is interesting, for it not only shows the infinitely short existence of the spark, but it also shows that chemical change in the sensitive film takes place in an equally minute interval of time.—*Engineering.*

ELECTRO-PHYSIOLOGY.

On the 6th of November, at Owens College, Manchester, Professor Stirling delivered a lecture on the electrical properties of the tissues, but especially of those composing the nervous system. There are about fifty species of fishes which are known to have specially modified organs for the generation and discharge of electricity. These organs when at rest do not discharge their electricity; but if the animal be irritated electrical shocks are discharged, which in some fishes are very powerful indeed. By means of electrical discharges these animals not only stun their prey, but they ward off the attacks of their enemies. The animal may discharge its batteries voluntarily, but after having done so for a considerable number of times the electrical organs become fatigued, just as muscles after severe exercise are fatigued. At first sight it might seem remarkable that certain animals are provided with structures which evolve powerful discharges of electricity. This however, is not by any means the most remarkable fact. When we know that the whole of the body of the animal is traversed by the electrical current at the moment it is discharged, it does seem far more wonderful that the tissues of the animal itself are not thereby affected; not even a muscle is caused to contract, although the discharge must necessarily traverse the nervous system as well as the muscles. The animals, therefore, have an immunity from the effects of their own shocks. Darwin admitted that the presence of these organs in a limited number of fishes was a fact not easily explained on the evolution hypothesis. Recent researches, however, have shown that the electrical organs are really modified muscular organs, or the terminations of nervous structures in muscles. This fact greatly simplifies the problem. Muscles and nerve, however, evolve electricity in the living condition; and a variation of the electrical conditions of a muscle, a nerve, or even of protoplasm generally is one of the best signs of the vital activity of these structures. With Galvani's experiments on the twitchings of the limbs of frogs, there commenced the investigation of electrical phenomena, which have led to such splendid results, not only in physiology, but to the development of new means of producing electricity and its numerous applications in the arts. The lecturer demonstrated the classical experiments of Galvani, Volta, Noboli, Du Bois Raymond, and others, showing historically on what lines our present knowledge of animal electricity had been reached.—*The Electrician* (London).

A TEN-THOUSAND VOLT TRANSFORMER.

The usual tests of insulation consisting only of a measurement of the insulation resistance afford very little guarantee, especially in the case of electric light cables, for the working strength of the insulation, seeing that the test is usually made by means of laboratory batteries having a comparatively low E. M. F.

At the "Menier" electric cable works in Paris-Grenelle an alternating current transformer, made by Messrs. Ganz & Co., of Budapest, has been used since March, 1888, for the purpose of testing cable insulation as well as any dielectric. This transformer is constructed with a primary coil for 100 volts and 70 amperes, and a secondary for 10,000 volts and 0.07 amperes, the ratio of transformation being 1 : 100.

The secondary coil is divided into 10 divisions, the ends of which are led to metal contact pieces with conical holes. By means of two plugs and two flexible leads, the di-electric to be tested can be subjected to a difference of potential of from 1,000 up to 10,000 volts, and its behavior observed.

In the primary circuit there is, as well as the generator, a double pole switch, in order to cut off the primary circuit entirely before altering the secondary difference of potential by shifting plugs. A Cardew voltmeter indicates for the control of the primary potential.

Concerning the construction of the transformer, it may be mentioned that the primary and secondary coils, as well as the divisions of the secondary, are carefully insulated from one another with ebonite. The metal pieces forming the terminalsof the secondary divisions are mounted on high ebonite supports, the metal plugs being also furnished with long handles of the same material.

The transformer, together with the terminals, are mounted on a strong base board, on which there is also a double pole switch with porcelain base and handle.

This method of testing the insulation of cables affords a far better guarantee for their safe working in actual use than that of testing by measuring the insulation resistance with a comparatively low E. M. F.—*Electrical Review* (London).

THE GEYER-BRISTOL METER.

The Geyer-Bristol meter, which is described on a later page, presents several features of interest. Every one will be struck with the ingenuity and simplicity of the idea, and we are inclined to think that it will prove of some considerable practical value, though it is to be expected that the indications will be somewhat sluggish. As an ammeter, at any rate, its advantages are obvious. It is also satisfactory to know that, according to the recent investigations of C. Cranz, the differences in the heating power of continuous and alternating currents (of the same mean value) are too small to affect the reading of industrial instruments, although, as a matter of fact, the alternating current has a slightly greater effect. This is a result which we venture to think might have been foreseen, since the heat generated when the current wave is at a maximum must take time to reach the surface of the wire, and we imagine, therefore, that the higher the thermal conductivity of the metal the more nearly identical will be the effects.—*The Electrician* (London).

INAUGURATION OF THE STATUE OF AMPERE.

ADDRESS BY M. CORNU.

We find in the history of science names whose lustre increases year by year as succeeding generations appreciate more fully the grandeur and the fecundity of the work with which such names are identified. Such is the name of André Marie Ampere.

Born at Lyons, on January 22d, 1775, your illustrious fellow citizen early displayed a wonderful intelligence joined to a prodigious memory; he learned everything spontaneously.

His father whose doom it had been to perish as a victim of the blood-thirsty passions of the day, had discovered his thirst for knowledge and sought to satisfy it. "As for my son (he wrote the evening before his death) there is nothing which I do not expect from him."

The future justified this paternal forecast. Young Ampere first turned his attention to transcendental mathematics. His first work "Considerations on the mathematical theory of gaming," which contains the solution of a difficult problem in the theory of probabilities, bears the mark of a vigorous and profound spirit. He wrote it in the midst of the most trying pre-occupations at Bourg, at the Central School of the Department of L'Ain, where he was professor of physics and chemistry in 1802 and 1803.

This first work attracted the attention of Delambre, who along with Villar was commissioned to recruit the teaching staff of the lyceums then in course of creation. A second work, "The application of the calculus of variations to mechanics," earned for him the patronage of Delambre, and enabled him to leave the unpleasant position which he occupied at Bourg. He was nominated professor of mathematics at the Lyceum of Lyons.

He was thus enabled to return to his young son, Jean Jacques Ampere, who became subsequently an eminent academician, and to his wife, who was in declining health.

On her death, residence at Lyons became insupportable to him. Fortunately his patrons, Lalande, Delambre, and Laplace, called him to Paris as "repitituer" of analysis at the "Ecole Polytechnique." There, sharing his time between the philosophers and the mathematicians, he was again able to enjoy his studies, and soon won the esteem of the learned world by the profundity of his views and the variety of his conceptions.

In 1808, he was nominated inspector-general of the University, and in 1809, professor of the courses of analysis and of mechanics at the Ecole Polytechnique. Finally, in 1814, he was elected a member of the Academy of Sciences in the mathematical section.

Further memoirs touching problems in the loftiest fields of mathematics raised him to the highest rank in that science. But these researches were merely the prelude to more important discoveries. From being a great mathematician he became a still greater physicist, and it is in this character that he will be most honored by posterity.

In the beginning of September, 1820, the Academy of Sciences heard of the discovery of Oersted, that the wire connecting the poles of a galvanic battery acted upon the magnetic needle.

A few days later Ampere completed this great discovery by giving precision to all the conditions of the experiment. He was the first who defined the electric current, giving it a direction, and summing up the phenomena in the celebrated rule that "the south pole is deflected to the left hand of the current."

He detected in the movements of Oersted's needle the solution of a great problem, which had for more than a century hovered before the physicists of all countries. These movements of the needle are signals which may represent letters, and the connecting wire, if prolonged, must transmit them immediately to any distance. Electric telegraphy, in principle, was thus invented.

Ampere afterwards applied all the power of his mind to the study of electro-magnetism. At every meeting of the academy he brought forward new discoveries. Step by step he announced the reciprocity of the action of magnets upon currents, the direction of a movable current by terrestrial magnetism, the reciprocal action of currents, creating thus a new branch of science, *electro-dynamics*, and finally identifying currents and magnets.

Thus, in a few weeks, there was effected a true revolution in physics. Magnetism, which had formerly been separated from electricity, ceased to be a distinct agent. The magnetic properties, regarded as peculiar attributes of iron and steel, became a general phenomenon, common to conductors of all kinds. Ampere discovered at the same time the proper form to be given to conductors in order to reproduce most exactly the properties of magnets;—this is the electro-dynamic cylinder, or solenoid, which is made by folding a metallic wire into a helix and traversing it by a current. The helix presents at its two extremities opposite poles. If suspended freely, it shows the north like a compass, and so long as it is traversed by the current, nothing distinguishes it from a real magnet.

There only remained one step to arrive at a discovery, which involves the most extraordinary consequences in science and industry. This step was taken by Ampere and Arago in the memorable experiment in which the two illustrious friends conceived the idea of introducing a bar of soft iron into the electro-dynamic coil. The electro-magnet was invented.

When Arago, wishing to express his admiration for the work of his friend, exclaimed before the Academy of Sciences: "We say the laws of Kepler, and we shall say the laws of Ampere," he foresaw the judgment of posterity.

But the supreme testimony of admiration comes to him from abroad, from the country of Davy and Faraday. Maxwell, an illustrious English savant, ventured to say: "Ampere is the Newton of electricity."

The name of our great physicist finally acquired its great renown on the day when, by a delicate homage to the memory of the great men who have contributed most to the progress of electrical science, Volta, Ohm, Ampere, Faraday, Coulomb, the electricians of all countries, assembled in congress, determined that these names should serve to designate the various electrical units. Since that day, over the entire world, the name of Ampere, a synonym for the unit of current, is pronounced by thousands of lips in the laboratories of savants, as well as in the most modest workshops.—*La Lumière Électrique.*

REMINISCENCES OF AMPERE.

THE city of Lyons is about to erect a statue in honor of the *savant* who discovered electro-magnetism. Professor Cornu, of the Academy of Sciences, will show at the inauguration how greatly dynamic electricity is indebted to him. We will here merely give, from *Le Figaro*, a few facts concerning his private life.

André Marie Ampere was born at Lyons, in the parish of Saint Nizier, on January 22d, 1775. His father was Jean Jacques Ampere, and his mother Jeanne Antoinette Sarcey de Sutières. Fifty-two years after his death Lyons has resolved upon raising a statue to its most illustrious son, who in his life time was less honored than he deserved.

The inauguration of the monument will take place in presence of the president of the Republic. M. Carnot, an old student of the Ecole Polytechnique, will thus render homage to the most eminent of its professors.

The childhood of Ampere was passed at Polymieux les Mont d'Or, near Lyons. Here, even before he knew figures, he made long calculations by means of pebbles and beans. He early displayed a wonderful memory and a prodigious power of assimilation. He devoted himself with equal and simultaneous ardor to botany and the study of Latin poetry. As he was also by nature a mathematician, we find him combining three distinct mental types. One of his earliest researches was the application of mathematics to games of chance. He proved rigorously that the professional gamester runs to certain ruin. This investigation of Ampere's, however, has probably not cured a single person suffering from the gambling mania.

His finest and most fruitful discoveries were made in physics. In 1802, the First Consul Napoleon, offered a prize of 60,000 francs to anyone who should effect a similar advance in electricity or galvanism to that due to Franklin or to Volta.

Ampere was then engaged in researches which immortalized his name by leading him to the electro-dynamic theory. In a memoir communicated to the Academy of Sciences, in 1812, he already indicated the principle of electric telegraphy. In 1819, Oersted, of Copenhagen, discovered the action of an electric current upon a magnetic needle. This result became in the starting point of one of the most beautiful inventions of the age. In eight days he conceived and realized the entire theory of electro-dynamics, and submitted his results to the Academy on September 18th, 1820.

The duties of an inspector-general of the University compelled Ampere to traverse France in all directions, and he had the curious habit of naming his theories from the places where they dawned upon his mind.

Great, however, as were Ampere's services to science, they would, doubtless, have been far greater if he could have kept himself from metaphysics. We know that in middle life Liebig bitterly regretted the time which he had devoted to such studies in his youth. Ampere, on the contrary, became more metaphysical as he grew older. He declined to answer a letter on physical and chemical topics which he had received from Davy, having, as he said, "no longer the courage to fix his ideas upon such troublesome things." He actually kept up a correspondence with Maine de Biron from 1805 to 1815, and he regretted that many of his friends did not care for metaphysics.

He was a believer in so-called animal magnetism, and admitted that in certain conditions of nervous excitement a man might see without eyes, and read a letter with his elbow. His mind was

active only when standing. If seated at a table, pen in hand, his ideas vanished.

Ampere was exceedingly short-sighted, and, in addition, absent minded.

Of the consequences of this defect some amusing instances are on record. On his appointment to a professorship at the Ecole Polytechnique he made his first appearance in the lecture room in an old, ill-made coat, which became a standing joke among succesive series of students.

Some of these young men pretended to be short-sighted, and by degrees persuaded the kind hearted professor to write figures of such a size that the largest black-board would scarcely suffice.

One day, when absorbed in the development of a difficult theory, he mistook a duster, covered with chalk, for his handkerchief, and wiped his face with it accordingly.

Ampere was an intimate friend of Chevreul. They dined together weekly in the Rue de Babylone, with an American geologist, in company of La Reveillére-Lepeaux and Volney. Here was formulated the law of the simultaneous contrast of colors. In M. Chevreul's garden Ampere strayed at will, pursuing an idea, solving a connundrum, or catching butterflies.

Ampere was married in 1779, but had the misfortune to lose his wife as early as 1805, a calamity from which he never recovered. He passed entire days on the banks of the stream where he had first met her, and spent the time in making little mounds of sand. His death took place on June 10th, 1836, at the College of Marseilles.

The statue about to be inaugurated is said to recall very vaguely the features of Ampere. When questioned on this subject, the sculptor declared that this deviation from truth was intentional. The object was to ornament a beautiful square, and he therefore represented a handsome young man, an Apollo, which Ampere never was.—*Telegraphic Journal and Electrical Review* (London).

ON THE MAGNETIZATION OF IRON AND OTHER MAGNETIC METALS IN VERY STRONG FIELDS.[1]

BY J. A. EWING, B. Sc., F. R. S., Professor of Engineering in University College, Dundee, and WILLIAM LOW.

EARLY in 1887, the authors communicated to the Royal Society the results of experiments made by subjecting iron to strong magnetic force by placing the sample, in the form of a bobbin with a short narrow neck and conical ends, between the pole-pieces of an electro-magnet.[2] The experiments have been continued and extended by using much stronger magnetic forces and by testing samples of nickel, cobalt, and various steels, as well as wrought iron and cast iron. The large magnet of the Edinburgh University Laboratory, kindly lent by Professor Tait, was used throughout the experiments, and allowed the authors to effect a high concentration of the magnetic force by using bobbins, the necks of which had a cross-sectional area of (in some cases) only $\frac{1}{1800}$ of the cross-sectional area of the magnet cores By this means the induction $\mathfrak{B}$, was raised to the following extreme values:—

In wrought iron	45,350	C. G. S.
" cast iron	31,760	"
" Bessemer steel	39,880	"
" Vickers' tool steel	35,820	"
" Hadfield's manganese steel	14,790	"
" nickel	21,070	"
" cobalt	30,210	"

The induction was measured by means of a coil consisting of a single layer of very fine wire wound upon the central neck of the bobbin. Outside of this coil, at a definite distance from it, a second coil was wound, and the magnetic force was determined in the annular space between the two. In a paper communicated to the Manchester meeting of the British Association, the authors showed that if the force so measured could be proved to have the same value as the magnetic force within the metal neck itself, it would follow that the intensity of magnetism, $\mathfrak{I}$, had begun to diminish under the action of excessively strong fields, in the manner which Maxwell's extension of the Weber-Ampere theory of molecular magnets anticipates. In the present paper the authors discuss at some length the question of how far the magnetic force within the metal is fairly measurable by the magnetic force in the ring of surrounding air, and they show that with the form of cones originally used the force within the metal must have been less than the force outside, by an amount probably sufficient to explain the apparent decrease of $\mathfrak{I}$. The form of cone suited to give a uniform field of force with sensibly the same value in the metal neck and round it is investigated; and experiments are described in which the condition necessary for a uniform field was satisfied. The results of these experiments are conclusive in showing that no considerable change takes place in the value of $\mathfrak{I}$ (in wrought iron) when the magnetic force is varied from about 2,000 to 20,000 C. G. S. units. Throughout this range of force, the intensity of magnetism has a sensibly constant value of about 1,700 C. G. S. units, which is to be accepted as the saturation value for wrought iron. The term saturation may be properly applied in speaking of the intensity of magnetism, but there appears to be no limit to the degree to which the magnetic induction may be raised.

To produce the greatest concentration of force upon the central neck the converging pole faces should have the form of cones, with a common vertex in the middle of the neck, and with a semi-vertical angle of 54° 44′. This form, however, does not give a uniform field in the neighborhood of the vertex. To secure that the condition is that d^2F/dx^2, d^2F/dy^2, and d^2F/dz^2 shall vanish, F being the magnetic force at the vertex, which is due mainly to the free magnetism distributed over the pole faces. The condition for a uniform field is satisfiod when the cones have a semi-vertical angle of 39° 14′. When this form is given to the cones, the magnetic force in the air immediately surrounding the central neck may be taken as sensibly equal to the force within the neck, and it therefore becomes practicable to measure the relation of the induction to the force producing it—that is to say, the magnetic permeability.

The greatest attainable concentration may be calculated by assuming the pole faces to be saturated, when the cones are such as to have maximum concentrative power (semi-vertical angle = 54° 44′). Under these circumstances the magnetic force at the vertex due to the free magnetism on the conical faces is—

$$18{,}930 \log_{10} \frac{b}{a},$$

where b is the diameter of the poles at the base of the cones, and a the diameter of the central neck.

The following are probable values of the intensity of magnetism when saturation is reached in the particular metals examined:—

	Saturation value of $\mathfrak{I}$.
Wrought iron	1,700
Cast iron	1,240
Nickel (with 0.75 per cent. of iron)	515
Nickel (with 0.56 per cent. of iron)	400
Cobalt (with 1.66 per cent. of iron)	1,300

Experiments were also made with specimens of Vickers' tool steel and other crucible steels, Whitworth's fluid compressed steel, Bessemer steel, Siemens' steel, and Hadfield's manganese steel. This last material, which is noted for its extraordinary impermeability to magnetic induction, was found to have a constant permeability of about 1.4 throughout the range of forces applied to it—namely, from 2,000 to nearly 10,000 C. G. S.

The results are exhibited graphically by curves drawn in Rowland's manner, to show the relation of the permeability to the magnetic induction. In the highest field examined the permeability of wrought iron had fallen to about two.

POINTERS.

.... WE now know the steam engine is really a heat engine. —*Sir Frederick Bramwell.*

.... LET us accept as an undoubted fact that a general distribution of power would enable the wants of civilized life to be better satisfied, and therefore would greatly benefit industry.—*Professor Ayrton.*

.... FOND Father:—"My son, which would you rather be, Shakespeare or Edison?"
Bright Boy (promptly) "Edison."
Father :—" Why?"
Son :—"'Cause *he* is'nt dead."—*Daily Paper.*

.... HE who wishes to keep abreast with the march of science to-day must leave the college and go to the workshop and into the dark corners of private laboratories, for investigators rarely have time to write, so that text-books are years behind the science itself.—*Professor Gray.*

.... IN America the electric light wires overhead are classed as dead or alive according to the result that happens on touching them. If you handle a wire and are alive after it, the wire is dead; if *you* are dead, the wire is alive. The wires are arranged within easy reach of an ordinary umbrella for testing purposes. and as a rule they are very much alive.—*Electric Plant* (London).

.... INSTEAD of frittering away his magnetism, Pacinotti showed how it could be concentrated, and thus he led the way to dynamos and motors becoming commercial machines. Pacinotti's science, engineered by Gramme, not only made electric lighting commercially possible. but led to electricity being used as a valuable motive power. It was in their work that the electric transmission of power in its modern sense sprang into existence.—*Professor Ayrton.*

OBITUARY.

Lucien Gaulard.

M. LUCIEN GAULARD, whose name is so widely and justly associated with the distribution of electricity by alternating currents and transformers, died on the 26th of November, at the St. Ann Insane Asylum, in Paris. M. Gaulard was born in 1850. His thermo-electric battery, exhibited in 1881 at Paris, first brought him into notice as an electrician. He gave much attention to the development of aniline products, and was the patentee of a process for tanning leather by electricity. But the significant feature in the work of his short life was the faith and energy which he devoted to demonstrating that electric energy can be transmitted over long distances by means of alternating currents and transformers. In England, the scene of his operations, it is admitted that, "from a practical point of view, the development of alternate current distribution was mainly due to his perseverance, energy, and enthusiastic belief in the capabilities of the system with which his name must ever be associated." Together with Mr. J. D. Gibbs, he began to develop his system, shortly after the Paris electrical exhibition. In his early proposals and undertakings he met not only opposition but ridicule at the hands of electricians. The recent complete success of distribution by alternating currents has completely justified his enthusiastic belief in the essential feature of his system; but it must be said that he persisted for a long time in a radically unsound method of applying it, viz., the joining up of an indefinite number of transformers in series. He did not take into account the counter electromotive force developed in each secondary generator. Experience was not lost upon M. Gaulard, and he was eventually convinced of his mistake.

Of the discourtesy, not to say disdain, heaped upon him in English electrical circles, let an English journal speak.—*Industries* says: "Many eminent electricians, who at that time ridiculed his ideas as almost akin to an attempt at producing perpetual motion, will now feel sorry that they did not take the trouble to investigate more closely the merits of his suggestions. Had they done so, they would easily have been able to divest his system from what was fallacious, and assist him to bring it to practical perfection. It is easy to find fault with a new and untried idea, and now that our conception of the dynamical principle involved in alternate current distribution has become clear, it is easy to point out at what particular point the early worker in this field erred; but six years ago the theory of transformers was not so well understood as it is now, and many electricians who ridiculed M. Gaulard's proposals at that time, could certainly not have helped him to carry them into practice, even had they been so disposed. Gradually, however, he succeeded in making converts. His exhibition at the Aquarium, and especially the trial at the Metropolitan railway, when a long circuit was worked from a central station at Edgeware road, caused electricians, to whom hitherto Ohm's law had been the beginning and end of their science, to think that after all there might be something in this new idea; and when M. Gaulard received the great prize at the Turin Exhibition of 1884, and was decorated by the King of Italy, the scientific world began to recognize his merit."

M. Gaulard's general plan of alternate current distribution has been taken up by many electricians and inventors in both Europe and America, and wrought out to complete success. The defeat of the Gaulard and Gibbs' patent in England, and the consequent loss of fundamental control of the new method of distribution, is said to have preyed heavily upon M. Gaulard's mind. It is, perhaps, to be regretted that he did not come to America where he won his greatest technical and financial success, and where the disappointments of his European career might have been assuaged by observation of the practical and commercial success that has attended the introduction of alternating current distribution by the American assignees of the Gaulard and Gibbs' invention.

.... THE engineer says distinctly: "Electricity is a form of energy—it is not a form of matter; it obeys the two great developments of the present generation—the mechanical theory of heat and the doctrine of the conservation of energy."—*W. H. Preece.*

.... IT only wants to be able to generate waves of any desired length in order to entirely revolutionize our present best systems of obtaining artificial light by help of steam engines and dynamos, which is a most wasteful and empirical process.—*Professor Ayrton.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

Annual Meeting of the Medico-Legal Society.—The Julien Cars on Fourth Avenue.—Another Trial of the Daft Motor on the Elevated Road.—Surface Street Railroads Making Examination of Electric Traction Systems.—Suit Against the Holmes' Electric Protective Co.—Proposed Electric Road to Coney Island.—The City of Newark Investigating Police Patrol Systems.—The Daft Company in Newark.—The New Jersey and Perth Amboy Electric Light Co.—Mr. C. O. Mailloux.—A New Electrical Paper.

AT the annual meeting of the Medico-Legal Society, held at the Fifth Avenue Hotel on December 12th, a paper was read by Mr. Henry Guy Carleton (who writes funny articles for the *Sunday World*) upon the "Best Method of Executing Criminals by Electricity." The committee's report, recommending an alternating current of 3,000 volts, was finally adopted.

An electric locomotive designed for regular railroad service, weighing 15 tons and shaped like the ordinary steam railroad engine, is being built at the New York Locomotive Works at Rome, N. Y. The inventor is W. H. Darling, of Brooklyn, N. Y.

A marked advance has been made in the use of accumulators by the Julien Electric Traction Co. on the Fourth avenue line. The cars now make three round trips without change of batteries. The cost per car per mile is stated to be 2¼ cents.

Another trial of the Daft Electric Motor Car, "Benjamin Franklin," was held on December 5th. A train of eight empty cars was taken up a grade of nearly two per cent. at a speed of 7½ miles an hour. On two occasions a speed of 30 miles an hour has been maintained with three empty cars, without the slightest difficulty. The regular trains on the Ninth avenue line run at a speed of 13 miles per hour with four cars. The Daft Co. has maintained a speed of 15¼ miles per hour with four cars, and carrying a load of over half of the seating capacity of the cars.

While the increase of traffic on the elevated roads has been very heavy during the past year the surface roads, with one exception, show a decrease. This fact has made plain to the executive officers of several of the surface roads that an increase in earnings must be brought about by a decrease in operating expenses, and a quiet but searching investigation is being made into the various electric motor systems. It is rumored that several of the stockholders of the Sixth avenue line favor the adoption of the Julien system.

A suit for $25,000 has been brought against the Holmes' Electric Protective Co., by Mr. Geo. H. Holt, of 24 East 58th St., who alleges that he contracted with the Holmes' company for watchman's and burglar-alarm service, and that during his absence from the city last summer his house was robbed of jewelry, bric-a-brac, dresses, and other valuables.

An electric street railroad from Brooklyn to Coney Island is being agitated. General James Jourdan, president of the Kings County Elevated Railroad is said to be identified with the enterprise, and is looking into the various systems.

An explosion of gas in a conduit at the intersection of Maiden Lane and Nassau st., shortly after midnight, December 20th, has provoked the inquiry by the daily papers. "Is New York on a volcano?" An eye witness thus reports the accident:—

"The heavy iron cap of the man-hole was blown into fragments, which went hurling high into the air, followed instantly by a fountain of flame, spurting up ten or fifteen feet. This was followed by a suffocating belch of foul gases. Fully forty feet from the man-hole I picked up a piece of the iron cap that would weigh at least four pounds."

A sensational report has been passed about among the trade journals to the effect that Mr. Henry Villard had secured $10,000,000 from German capitalists for the extension of the central station business of the Edison company. It is not known that any officer of the Edison company has asserted this to be a fact. There is little if any doubt, however, that Mr. Villard has secured a large sum from a Berlin syndicate and has purchased large quantities of stock in the several Edison companies.

The *Herald* of December 21st claims to have foundation for asserting that the Villard syndicate have formulated a plan for the consolidation of the Edison and Westinghouse companies, and that interested parties are now in conference. Secretary Hastings, of the Edison company, is reported as saying that the Westinghouse people had been haunting Mr. Villard's office for a week past, offering to consolidate on terms which have not yet been agreed to. Mr. Geo. Westinghouse, Jr. was found in conference with several mysterious gentlemen at his branch office in this city. He is reported as saying: "We have more business than we can attend to, and that ought to satisfy any set of men possessed of reason."

The *Herald* asserts that the capital of the consolidated company is to be $80,000,000; $40,000,000 of the same to be good, ordinary, everyday water. A very pretty story.

Telegraphic communication with the Island of Hayti, now the scene of revolution and with which questions of state have arisen, has been entirely severed. Investigation reveals a fierce war between the French cable company, whose cable is the only one touching at Haytian ports, and the various other cable companies in the West Indies.

The new lines of the French company run from Santiago de Cuba to Mole St. Nicholas in Hayti, then along the Haytian coast to Puerta Plata, St. Domingo, thence by land to the City of St. Domingo. A cable is laid from there under the Caribbean Sea to Curacoa Venezuela, and from there to La Guayra. The company depends for an outlet to the United States and Europe on the West Indian and Panama Cable Co., whose lines extend from Santiago de Cuba to Kingston, Jamaica.

The Cuban Submarine Co. own a line from Santiago to Havana via Cienfuegos, Cuba. The International Telegraph and Ocean Co. own the cables from Havana to Key West and Punta Rassa, Fla., and control the one from Kingston to Porto Rico and running along the Windward Islands to Trinidad. The Panama company, however, operates both of these lines. This company, which is granted a subsidy of £2,000 per year by the Jamaica government, claims the exclusive right to land its cables on Cuban soil, and hence refuses to transmit messages to or from the French company.

Dr. Norvin Green, president of the Western Union, lays the blame upon the Spanish authorities, who refused to allow the French company to land its cables in Cuba.

President Geo. W. Plympton, of the electrical subway commission, Brooklyn, has handed in his, report for the year ending November 30th, 1888

These are the main points presented in the report. "The aggregate length of underground conductors has been increased from 1,433 miles to 2,928. There are still 5,111 miles of aerial conductors. Those of the various district telegraph companies and of the Gold and Stock Telegraph Co. are on housetops, and not poles, and the board has continued to permit them to operate above ground. Of the 4,402 miles of telegraph and telephone wires, more immediately the subject of the operations of this board, it is reasonable to expect that nearly all of the 236 miles of telegraph wires now carried on poles will be removed. Of the remaining 4,176 miles of telephone wires, a considerable proportion is required for terminal distribution in connection with the subway system; another large part will be removed from poles within the next few months, and much, if not the greater part, of the remainder is so distributed that it is not practicable at present to combine the separated wires in cables.

"The elements both of advantage and of difficulty vary so widely in different cities that comparisons based on wire mileage alone are too superficial to be either just or useful. This board does not claim, therefore, special credit for the fact that the actual increase of underground mileage has been considerably greater in Brooklyn during the past year, than in any other city.

"There have been removed 225 poles, carrying over fifty miles of wire. This includes all the poles on Broadway, and nearly all those on Fulton and Myrtle avenues, from which the few poles now remaining will shortly be removed. There are about eighty miles of overhead electric light wires remaining, and more than half of these will be transferred to the elevated railroads at an early day. When this shall have been done four-fifths of the poles and wires of this class will have been removed.

"But satisfactory as this result may be, and great as is the relief thus afforded to business streets, the problem of electric arc light distribution will not thereby be solved for the future. For the most serious features of the situation, as all who have undertaken to deal with it have been compelled to admit, is the immense rapidity with which the use of electricity, particularly as transmitted in the form of currents of high tension, is extending. The perfecting of a practicable and safe subway system is still called for, though at the present moment the need of such a system is more imperative in other cities than in Brooklyn.

"The electric lighting companies have during the past year leased the right to place their wires upon the elevated railroad structures of the city; and, since these structures occupy the principal business streets, such as Fulton and Myrtle avenues and Broadway, where the larger part of the electric arc lighting is done, the arrangement has proved specially favorable for the rapid removal of poles and aerial conductors of this class."

The New York aldermen have finally granted permission to the Fourth avenue road to use electric motors. The only argument brought to bear against the ordinance, was that the street railway company would not consent to pay into the city treasury a certain percentage of its gross receipts as the Fulton street company agreed to do, while it was claimed a very large decrease in operating expenses would be effected. New cars are now being built by Messrs. Brill, of Philadelphia, and will take the place of the horse cars as fast as equipped.

The work of laying the Bentley-Knight conduit on Fulton street has already begun, and attracts throngs of people daily.

The patrons of the Casino theatre on Christmas Eve were surprised by noticing boxes attached to the backs of the new opera chairs, upon which an announcement could be read that by dropping a quarter in the slot, a pair of opera glasses would be furnished for the evening's entertainment. An electric device gives notice on an annunciator of the removal and the return of the glasses. This system will soon be placed in the Fifth Avenue, and other theatres.

The police commissioners of Newark, N. J., are investigating police patrol signaling devices, with a view to the adoption of a system for that city.

The Essex Passenger R. R., of Newark, has received permission to erect poles and wires in order to give the Daft Co. an op portunity to demonstrate the advantages of its system.

The New Jersey and Perth Amboy Electric Light Co. was organized some months ago by Messrs. Seabury and Johnson, of No. 18 Cortlandt st., and construction has already begun for an arc and incandescent system.

Mr. C. O. Mailloux, the well-known electrical engineer, has taken charge of the electric power department of "*Power-Steam*," a monthly steam engineering paper.

Mr. Ralph W. Pope, secretary of the American Institute of Electrical Engineers, and Mr. George H. Stockbridge, formerly manager of the patent department of the "*Electrical World*," announce the publication of a new electrical journal devoted to the electric power interests.

NEW YORK, December 29, 1888

PHILADELPHIA.

A Suit Against the Consolidated Electric Light Company.—The Keystone Company's Franchise.—Lights for the New City Hall.—General Permission to Run Electric Service Pipes.—The New Western Union Office in the Rotunda of the Post-Office.—Extension of Electric Street Lighting.

Walter and Stuart Wood, of this city, have secured judgment in the United States Circuit Court in New York for $18,550 against the Consolidated Electric Light Co., being the principal and interest on $17,500 worth of bonds held in the defendant company. The complaint was that interest had not been paid.

When judgment was entered the company answered that forged and fraudulent bonds had been issued, and that to secure bondholders a new issue had been made, exchangeable for the original bonds, and that the complainants had not exchanged their bonds. The complainants entered a demurrer to the sufficiency of the answer, and were supported by Judge Wallace.

The electrical sub-committee of councils having under advisement the granting to the Keystone Electric Light and Power Co. the privilege to lay conduits and wires in certain streets, reported to the committee proper that they had decided to report favorably. The city solicitor, who was asked his opinion, said that the board of highway supervisors, the company and himself were satisfied with the provisions of the supplemental ordinance granting these privileges, and there was to him no apparent objection to giving the right. The ordinance, like all others granting privileges to electric light companies, provides that the company shall give the city, for municipal purposes, the use of one duct or three working wires. The bill will be reported favorably to councils.

An ordinance for an appropriation to put lights around the new city hall was referred to the finance committee.

Councils have authorized all electric light and power companies to introduce electric service pipe into stores, dwellings and all kinds of public buildings between December 1, 1888, and March 1, 1889, upon the payment by the companies of $5 for each permit to open streets during the period named.

The Western Union Telegraph Co. have opened a new office in the rotunda of the post-office here with thirty-eight wires in full operation. A full district messenger service has been organized, and the office will be open night and day. Every convenience has been provided. By a signal the wires of the main office can be switched on, and all parts of the country reached. The wires at the post-office are all underground.

Diamond street, from Broad west to the park, is to be lighted by electricity. Diamond street is a splendid thoroughfare, and with the electric lights in operation will present a very handsome appearance. The distance to be lighted is about two miles.

PHILADELPHIA, December 18, 1888.

BOSTON.

Sulphureted Hydrogen in the Conduits.—The Underground Franchise.—Damage to the Nantucket Cable.—The Long-Distance Telephone System.—The Telephone Suit.—Mr. Leonidas Le C. Hamilton's Course of Lectures.—The West End Street Railway Co.: A Part of the Electric System Tested.—The Monthly Statement of the American Bell Telephone Co.—New Corporations.

STRANGE to say, putting the electrical wires underground does not put them out of mind. It was thought by some of our good citizens that when the wires were all buried peace would prevails

but they find that even then they "will not down."

Scollay square, Brattle street and Cornhill have for a long time been afflicted with an obnoxious odor, and a petition signed by the business men has been addressed to the Board of Health, setting forth that, through the operations of an electric company, in pumping a foreign substance into the conduits, the premises of the petitioners have become seriously infected and the health of many persons endangered. To prevent the destruction of the lead pipes enclosing the wires, by the action of the acetic acid in the creosote, with which the conduits have been treated, the company have pumped sulphureted hydrogen into the wooden ducts.

The general impression is, that the corporation who have obtained rights for underground conduits in this city, over the opinion of the city solicitor and the vetoes of the mayor, will not do much business other than selling stock, for some time to come. In fact there does not seem to be much room for such a corporation to do work, as the telephone company and the Edison people have their wires down, and the arc light companies are not being forced underground anywhere, so far as known.

Lieutenant Wright, of the Signal Service, who has investigated the damage to the Nantucket cable, says that the seas that came in on the southern portion of the island were the most dangerous of very many years. They washed away about 200 yards of the beach and cliffs three miles below the Surfside life saving station, and carried away the cable box in which the connection was made with the cable and land line. The cable comes in at that point from Martha's Vineyard, and the link in the system is a vital one. Not only did the sea take possession of the cable box, but it washed down two of the poles carrying the land line. The sand was being deposited over the cable bed to the amount of thousands of tons, and Lieutenant Wright saw that a great loss of property would occur if he did not lift up the end of the cable at once. He sent a gang of men off shore a third of a mile, where the line was, who grappled for it. It was raised, and is now buoyed there, so that when the work of restoring the connection is begun, the inshore end will probably be raised without much difficulty. When a similar mishap occurred at Block Island some time ago, it took 16 yoke of oxen to pull the heavy wire out of the sand into which it had become imbedded. The work is hazardous, on account of the tremendous undertow that exists there, and to prevent any loss of life, the Surfside life savers have agreed to remain on shore close by the end of the cable, ready with a Hunt gun to lend assistance if it should happen to be needed.

Every innovation, whether in the modes of conducting business or in other respects, is progressive in this age, and no novel device has been more marked for rapidity of improvement than the telephone. From short-distance communication, which was at first considered a marvel, audible conversation can now be carried on with ease over wires hundreds of miles long. New York, Buffalo and intermediate points were opened up to representatives of the press yesterday, not as an experiment, but to show the practicability and usefulness to the business and social public of a system that has been for some months in successful operation. It has been brought to a positive certainty by auxiliary appliances that have borne severe tests. The American Telephone and Telegraph Co. has its lines in perfect order. The main office is situated at 53 Devonshire street. In a little closet at one end of the room is a table from which projects a steel arm, having upon its end what appears to be a common speaking tube. In talking, one must hold his mouth well into the transmitter, instead of a short distance away, as in the ordinary machine. After talking with Providence, New York and other distant places, the operating room at 215 Franklin street was visited. Here four operatives are engaged in making connections with the different points. All the connections are kept upon slips, which are turned into the central office every night. Upon these slips are put the time of connection, time consumed in talking, and the number or name of the person sending the message. The first public station is at 42 Summer street. The telephones are in closets, which are built double to prevent sound entering. The upper part is of two thicknesses of plate-glass, over which curtains are hung. The inside is lined with embossed leather, which gives the room a very handsome appearance. At the Adams House is another station. Here are two "booths." The attendants are in uniform. Another station is at No. 50 Pearl street, which is largely used by the business men of that section.

The popularity of the long-distance telephone is rapidly increasing, and more stations will doubtless soon be needed.

United States District Attorney Galvin, on the 10th inst., filed in the United States Circuit Court an amendment to the bill in the suit of the United States *vs.* the Bell Telephone Co. The amendment sets up the Drawbaugh patent. The case was brought up in the Circuit Court on the 12th inst., and it was stated by Judge Colt that the United States Supreme Court had overruled the defendant's demurrer; therefore he ordered the defendant to plead or answer the complaint, or do both, within 60 days.

Mr. Leonidas Le Cenci Hamilton has been delivering a course of lectures in Horticultural Hall, upon "Electricity and Magnetism" and kindred subjects, illustrating his theories concerning the nature of all forces.

Before the board of aldermen, on the 26th ult., an order was passed granting the West End Street Railway Co. the right to lay down tracks on Harvard Bridge, beginning at the line which separates the city of Cambridge from the city of Boston on Harvard bridge, thence on the bridge and West Chester Park to Beacon street, to connect with tracks on Beacon street.

The same company was authorized to maintain the electric system of motive power in the operation of its cars, by the overhead system, between West Boston bridge and Bowdoin square. A letter was received from Mr. Henry M. Whitney, president of the company, agreeing that if the conduit system proves successful he will substitute a conduit for the overhead system.

A part of the West End Brighton line of railroad which has been fitted for overhead electric propulsion of cars, was tested on the forenoon of the 4th inst. The engine in the power house at Allston was started up, and five minutes afterward the car left the Oak square stable with five persons aboard. The climb up the hill was made easily, and from there to Harvard street, Allston, the run was made without event, the car reaching a speed of 16 miles an hour. On Harvard street, near the Hawthorne turnout, the track was covered with dirt, and it was almost impossible to move the car, as no connection could be made through the rail which is a necessity. While experimenting here with one motor, something went wrong which caused the burning out of a switch box. But this did not delay the car, as it is so arranged that it can be run from either end. On the return trip, near the corner of Cambridge street, the car in taking a switch jumped the track, all four wheels leaving the rail. It was but the work of a few minutes to run it on the rail again, and this without apparent effort. Twelve cars are already fitted up ready to run. They were built by the Newburyport Manufacturing Co., are lighted by electricity and painted a robin's egg blue. They are lettered "Beacon Street, Brookline," and "Brighton via Boylston street and West Chester Park."

The output of telephones by the American Bell company for the month ended November 20, and the year to date, with comparisons, is reported as follows :—

November--	1888.	1887.	
Gross output	3,861	4,330	Dec. 469
Returned..........	2,452	2,667	Dec. 215
Net output..........	1,409	1,663	Dec. 254
Dec. 21 to Nov. 20—			
Gross output....................	49,661	48,670	Inc. 991
Returned	21,399	24,695	Dec. 3,296
Ne. output.	28,262	23,975	Inc. 4,287

Lenox Gas and Electric Co., capital $30,000. W. R. Plunkett, president; C. E. Merrill, treasurer; W. R. Plunkett, Alex. Kennedy, T. T. Robinson and R. D. Wilson, directors.

Lee Electric Co., capital $15,000. Wellington Smith, president; David Dresser, treasurer; the same and T. T. Robinson, directors.

The Dedham Electric Light Co. has been incorporated, with a capital of $25,000; John A. Bullard, president, Ferdinand F. Favor, treasurer. Also the J. W. Bailey & Sons' Co. of Boston; capital $20,000; Edward S. Bailey, president, Willard L. Bailey, treasurer.

BOSTON, December 17, 1888.

CHICAGO.

Effect of the Victory of the St. Louis Telephone Company.—Further Stages of the Controversy in Chicago.—Hundreds of Business Men Protest Against the Unsettled Condition of the Affair.—A Bitter Contest for the Street Lighting Contract at Elgin, Ill.—Annual Reception of Railway Telegraphers.—Installation of a 10 h. p. Sprague Motor.—The Coming Electric Light Convention; Extensive Preparations for Exhibits.—The Inter-State Telephone Company Summarily Enjoined.—Street Railway Notes.—A Phonograph Company.—Personal Mention.—Trade Notes.—The City Lighting Plant Started Christmas Day.—Detroit Storage Batteries in Professor Gray's Laboratory.—The Chicago Electric Club.

THE decision in the St. Louis telephone case was received with the greatest interest in Chicago, and the officers of the telephone company were in a mood that was almost hilarious. Had the decision been against the St. Louis company it would have been considered a precedent. The Chicago city council in all probability would alone have imitated the St. Louis aldermen. The telephone officers claim the decision will practically put a stop to the movement in Chicago, which was aimed at securing a reduction of rates, and they were eager to talk of the situation. F. H. Winston, attorney for the company, who has conducted the proceedings in the controversy here, said: "We do not anticipate any further trouble in this city. I consider the whole question settled. The City of Chicago will not attempt to re-open a fight without any ground upon which it can stand."

"But suppose the city secures the power to regulate rates from the legislature?"

"Then we shall probably follow the course pursued in Indiana. You know that we ceased operations there. We will do the same

thing here and leave Chicago without telephones. If the people of this city want to be unreasonable they shall be obliged to take the consequences. No other telephones can be operated. That too has been decided. We have the situation in our own hands. We are willing to do what is just and reasonable, but we shall demand the same treatment at the hands of the city."

Judge Green, the corporation counsel, was deeply interested in the result. It will be seen that the position assumed by him has been sustained in every respect. He is, of course, naturally elated over this fact. When questioned as to the probable course of the city in the matter, the legal adviser of the city hesitated a moment, and then said: "Well, I don't know exactly what we can do just now." The tone of his voice indicated that he shared the feeling of the city council and members of the anti-telephone committee that the company had won a great victory and was in a firm position. That is the general impression, and conservative business men think the best thing the council can do is to come to an understanding with the company.

The progress of the controversy is noted in the following brief report of meetings of the city council and its finance committee. In the early part of the month when the finance committee of the council commenced anew their attempt to solve the telephone problem, they found their way blocked. The committee rather expected to recommend an ordinance reducing subscribers' rentals in imitation of the St. Louis act, but an opinion of corporation counsel Green was received stating that this right did not vest in the council; that an appeal to the legislature for a grant of the desired authority must be made. At the next meeting of the committee, a proposition was made on behalf of the telephone company, offering by way of compromise the free use of instruments for municipal offices, for fire department and police department sets at nominal figures, and 2½ per cent. of its gross receipts. In return, the company asked for the right to extend its wires and to operate its system without threats of vexatious litigation. Representatives of the druggists, liverymen's, and undertakers' associations were present, and protested against the acceptance of any ordinance which did not provide for the reduction of charges to subscribers. On the day following, the company served on the mayor notice, that in the future applications would be made in the name of the Bell Telephone Co., to which a franchise had originally been granted, but which the council holds is void on account of non-use.

At the next meeting of the council, a resolution was adopted instructing the commissioner of public works to refuse all applications asked for in the name of the Bell company.

At the council meeting, December 15th, four hundred business men were present to protest against further delay in settling the question, but no action was taken.

An unusually bitter fight has been waged over the contract for lighting the streets of Elgin, Ill. Charges of bribery and corruption have been numerous, and have been made against both the aldermen and representatives of electric light companies. On December 8th, the contract was awarded to the Jenny Electric Co., of Indianapolis. The action was not legal on account of technicalities, and it was decided to re-advertise for bids.

The Railway Telegraphers of Chicago, gave their annual reception December 6th.

The Sprague Motor Co.'s western office has installed a motor in the rooms of the gold and stock department of the Western Union Telegraph Co. It is of 10 h. p. capacity. The motor runs two Edison dynamos, the current of which is utilized in running the tickers and for lights. Current for the motor is supplied by the Edison circuit.

The executive committee of the National Electric Light Association proposes to make the Chicago convention notable in the way of exhibits. A large hall will be hired for the purpose of displaying inventions of all kinds.

Judge Blodgett, in the United States Circuit Court, has refused to give the Inter-State Telephone Co. further time to prepare its defense to the charge of infringement preferred by the Bell company, and has issued an injunction restraining it from further operation.

The Topeka Electric Road, which the Thomson-Houston company is equipping, will be 16½ miles in length. The same company has taken a contract for extending the electric road at Wichita, Kans.

The Illinois & Indiana Phonograph Co., of Chicago, has been incorporated by Green B. Raum, Frank Z. Maguire and Joseph Kirkland. The company will operate in Indiana and Illinois, having secured the exclusive license to rent graphophones and phonographs in these two states. The company exhibited for several days the instruments in a hotel parlor where they attracted no little attention.

Mr. E. M. Barton, president of the Western Electric Co., left Chicago for Europe some weeks ago and will pass the holidays with his family in Berlin. Mr. Charles S. Scribner, electrician of the same corporation, is in Antwerp, at the headquarters of the Western Electric Co. in that city.

Mr. B. E. Sunny, the president of the Chicago Arc Light & Power Co., has taken a position in the Chicago office of the Thomson-Houston Co. He still retains the presidency of the former corporation. C. H. Wilmerding has been appointed superintendent of the Chicago Arc Light & Power Co.

Conant & Hood will hereafter represent the New York Accumulator Co. in Chicago. They have succeeded to the business of the Northwestern Accumulator Co.

The city electric light plant was put into operation for the first time on Christmas Eve, and for the first time in the history of Chicago the central part of the city was brilliantly illuminated. The principal streets in the business district on the south side are lighted, and on the west side the lights illuminate Madison street for two miles. The central station is located on Jefferson street, near Van Buren. The dynamo room contains 16 Western Electric 35-light generators. Power is supplied by a 400 h. p. Wright engine. Only 300 lights are utilized at present. The system will be extended from time to time. The fact particularly insisted upon by city electrician Barrett, and Chicagoans in general, is that this system is the largest underground plant owned by any city in the world. The cables end in a Western Electric switch-board, so arranged that any dynamo can be connected on any circuit in a few seconds. The dynamos are not connected in series, but each supplies its own circuit. The circuits are so laid out that the potential can not be higher than 1,000 volts. The system has given thorough satisfaction, and there are already plans suggested for extending it considerably. There is talk of employing the tax which the aldermen hope to obtain from the telephone company in extending the system.

At Professor Gray's laboratory in Highland Park, there is a new installation of Detroit storage batteries. They are charged by current from a 40-light United States company's dynamo. The accumulators supply current for lighting the professor's house and in illuminating the laboratory when the generator is not in operation. It is proposed also to light the Presbyterian church in the same way. The batteries are considered the reserve force of the laboratory. If the engine should break down the dynamo can be employed as a motor deriving its supply of current from the cells. Professor Gray says his telautograph will be put into commercial use in the spring.

At the next meeting of the Electric Club, January 7th, the members will discuss the subject of insulation. At the last meeting Dr. George W. Whitefield presented a paper treating of the evil results attending the use of dissimilar metals as filling material in the mouth. He demonstrated by a galvanometer that the employment of amalgam and gold filling would cause the generation of an electric current, the effect of which would be destructive.

CHICAGO, December 22, 1888.

MONTREAL.

The Lachine Rapids to be Utilized.—Proposals for Lighting the City.—The Police Ambulance System.—The Suit of the Royal Electric Co. vs. Edison Company.—Recent Sales of Lighting Apparatus.

YOUR readers, doubtless, have heard of the Lachine Rapids, and many may have had the pleasure of a trip down its raging waters. Only by such a trip can one fully appreciate its force.

Several years ago a charter was obtained with power to develop the natural force now uselessly expending itself at the rapids; but only recently has there been any active preparation toward a utilization of the magnificent power obtainable there.

A syndicate has, however, purchased the Isle au Heron, situated at the head of the rapids, and through which there is a natural channel. This company propose to deepen the island channel and build breakwaters, thus directing a large volume of water through the works from which, it is estimated, 250,000 h. p. can be obtained. The island is some distance from the main land, and about seven miles from Montreal. The power developed will probably be transmitted to Montreal by the electric method and there converted into light and power.

The proposal that the city do its own lighting, mentioned a month ago, has led to an animated discussion, both in the council and public prints. The Royal Electric Co. have a contract with the city with three years to run. They propose to terminate the contract and make a new one for ten years at 42½ cents per lamp. They are at present paid 60 cents per lamp. The Edison company made a counter proposal of about 32 cents per lamp. The Canadian Electric Light Co., who propose to operate from the Rapids, have made a proposal of 30 cents per lamp, less than either of the former proposals.

The Royal company now come forward with a proposal of 40 cents per lamp under limitations; as the Royal contract is exclusive, they will probably do the lighting.

The Toronto Electric Light Co. have recently proposed to terminate a contract with two years to run, and to light the city of Toronto at 35 cents per lamp per night.

The ambulance system is now so universal an adjunct to a complete Police system it creates considerable astonishment to have a Canadian city lay claim to having first inaugurated it. However, chief Davidson, of Sherbrooke, says his system was in operation August 12, 1882.

The hearing of the Royal Electric Co., Sawyer-Man, and others, *vs.* the Edison company, before the Commissioner of Patents, for the annulling of the Edison patents, has been finished. The commissioner, however, reserves his decision.

The Sherbrooke Gas and Water Co. have purchased two Royal and two Ball arc machines, and will do electric lighting in addition to gas lighting.

The Edison company report Chatham, N. B. central station, 300 lights; Gazette Printing Co., Montreal, 1,050 lights; Cornwall M'f'g. Co., 450 lights; C. P. Ry. Steamer New, 225 lights; C. P. Ry., Alberta and Athabaska, increase 60 lamps each. Brandon, Manitoba central station, 450 lamps; Moody and Sans Terrebonne, Que., 150, and Connell Bros., Woodstock, 300 lamps; Intercolonial Ry., Moncton, N. B., 450; Pembroke Electric Light Co., central station, 1,000 lights.

The Royal company report 25 arcs, River du Loupe, Que.; Cumberland Coal and Ry. Co., 15 arcs; St. Catherines, increase of 35 arcs; Geo. T. Davis, Levis, Que., 15 arcs; Winer, McKichnie & Co., Granby, Que., 50 incandescents; Vancouver Foundry and Mach. Works, 50 incandescents. Their alternating system is in operation, and among other installations are 500 incandescents in the City Hall.

The Edison company report in addition to the large sales made by them, the sale of an electric road (Sprague system) 5½ miles of track, 5 cars, at Vancouver, B. C.

MONTREAL, Que., December 19, 1888.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall street, New York city.*

AN UNARMORED SUBMARINE CABLE.

[101.]—I have read with interest the letters of Mr. David Brooks and "W. M. C." in your November and December issues upon underground and submarine cables. In connection therewith it may interest your readers to know the details of the manufacture of a submarine cable now being made in this city by the Bishop Gutta Percha Company, said cable being made according to specifications furnished by Capt. Samuel Trott, of the repairship *Minia*, and Professor F. B. Hamilton, electrician of the Anglo-American and Direct Cable companies.

The stranded copper conductor is first insulated with gutta-percha, then sewed with soft hempen yarn saturated with tar, then with an armor of harder twisted hempen yarn. In order to give the cable weight and stability the interstices between the threads of hempen yarn, as also between the two layers are filled with a compound of mineral pitch and silica, and a heavier coat of the same compound is put upon the outside by running the cable through dies prepared for that purpose. The silica compound serves to "weight" the cable and protect it from the attacks of the teredo.

The usual iron armor is entirely dispensed with. In all of the deep sea cables the iron covering has been found to be badly deteriorated, while in cables which have been under water for more than twenty years there has been no appreciable change in the tarred hemp bedding or the gutta-percha insulation.

Experiments recently made show that the iron armor is unnecessary, and that cables can be made lighter, cheaper and more durable without it.

The cable we are now making ,forty miles in length; will connect the Islands of the Sandwich group in the Pacific Ocean, and we understand that an English company has decided to lay the same kind of cable from Vancouver, British Columbia, to the Sandwich Islands, thence to New Zealand, thus completing the electrical circuit of the world.

HENRY A. REED.

DR. ATKINSON'S "ELEMENTS OF ELECTRIC LIGHTING."

[102.]—I am informed by the publisher of my recent work, "The Elements of Electric Lighting," that various English publishers propose to prohibit its sale in England, on the ground that it contains matter appropriated from English electric works published by them.

As I have always had such contempt for plagiarism, that I seldom even quote from another writer, preferring to use my own phraseology when adopting the ideas of others, I was much surprised to learn that such a charge had been made, and must infer that it is not possible that any of these gentlemen can have carefully read or examined my book. A charge of theft, literary or otherwise, "cannot be sustained till the property is found in possession of the thief and identified," and the burden of proof rests upon those bringing the charge. My work is before the public, and no one can show a single line which I have appropriated from any other writer except in my summary of installation rules, pages, 254 and 255, which I do not claim as my own. I found these rules given in common by different writers and modified them to suit my purpose.

In my chapter on the storage battery I adopted the theory of Gladstone and Tribe, using my own phraseology, and giving them full credit, both in my introduction and on page 218.

As stated in my introduction, I consulted the works of several different writers, mentioned my name, and embodied in my own language, modified by my own ideas, such matter as I found adapted to my use. This I understand to be the privilege of every writer. No scientific writer can claim to be wholly original; his writings are necessarily based on information derived from others whose ideas have become incorporated into his own body of thought. And as the object of a book like mine is to give the latest and most reliable information obtainable on the subject and not merely one's own peculiar views, I not only consulted other writers but made a thorough practical examination of the various kinds of apparatus described and the principles of their operation; visiting factories and inspecting machines and apparatus in the various stages of construction; conversing and corresponding with inventors and manufacturers; examining patents, and by every possible means seeking full and accurate information on every point.

My illustrations were obtained from various sources; some from books, pamphlets and periodicals, others from cuts lent me by patentees and manufacturers, and others from my own drawings; most of those from outside sources requiring modification to adapt them to my use. Some of these illustrations are the same as those found in English books, and yet even these are, in many instances, identical with those from cuts lent me by American manufacturers, while others are found in common in various electric works; so that I had no evidence that any of those copied from English works were from original drawings designed for any particular book; indeed the authors themselves acknowledge that their illustrations were in part obtained from outside sources; hence I have only followed the common practice of others by copying such illustrations as I found adapted to my use, for which, in my introduction, I have given full credit.

English electric books have had a large circulation in the United States, and common courtesy would seem to require that my book should have the same opportunity for circulation on its merits in England.

PHILIP ATKINSON,

LITERATURE.

REVIEWS.

Traite de Télégraphie Sous-Marine. Par E. WÜNSCHENDORFF, Ingénieur des Télégraphes, Directeur de Télégraphie Militaire (469 gravures dans le texte). Paris Librairie Polytechnique, BAUDRY ET CIE, Editeurs, 1888. Large octavo, paper, 556 pp.

FIRST NOTICE.

THIS treatise consists of the series of articles on submarine telegraphy, contributed by M. Wünschendorff to the pages of *la Lumiere Electrique*, during parts of 1887 and 1888, with slight rearrangement and a few additions, the latter intended to bring the work abreast with the latest developments in apparatus.

Although it is but thirty years since the first Atlantic cable, in its few weeks of use, demonstrated the possibility of realizing what the incredulous called the dreams of Frederic N. Gisborne and Cyrus W. Field—not to mention earlier believers and workers—and little over twenty years since commercial success was attained in establishing telegraphic communication between the old and new worlds,—although ocean telegraphy is of so recent date and has reached such enormous proportions as an industrial art—its familiar use and the diversion of popular interest to still more recent electrical developments, the telephone, electric lighting and transmission of power, have somewhat lessened its hold upon the attention of the public, and of electricians as well. Amidst, therefore, the whirl and din prevailing in electrical circles at present it is agreeable and restful to take up M. Wünschendorff's book, to read afresh the story of submarine telegraphy, from the suggestion of it which the author finds in Sœmmering's firing gunpowder at a distance at St. Petersburg, 1807–1808, and at Paris in 1813 through a submerged wire, through its gradual development in crossing the channels and seas of Europe up to the successful establishment of an Atlantic line, and the subsequent completion of the magnificent chain of cables connecting all the continents of the world.

Part i, some fifty pages, is devoted to the historical sketch above referred to. Parts ii, iii, iv and v treat, in their respective order, the composition and manufacture of submarine cables;

laying and repair; electrical testing, the discovery of faults; and the working of submarine lines. In its scope the volume reaches over the entire subject of submarine telegraphy, and so far justifies its title, "A Treatise." The work will be of interest and usefulness to general readers through its very full exposition of the processes and methods of so important an art as ocean telegraphy.

British names necessarily predominate in any general account of cable manufacture, promotion or operation; and the part which English genius and enterprise have played therein is exhibited in every part of M. Wünschendorff's book from the preliminary historical chapter to the end.

The work is copiously illustrated; the engravings are clear in their intention and fairly good, although not handsome.

In the chapter on signaling apparatus we miss any mention of Mr Charles Cuttriss's modification of the siphon recorder.

A CALENDAR WORTH HAVING.

CALENDARS of the complimentary-commercial variety, received in such abundance at this season, that it is impossible to mention or acknowledge them all, are usually handsome and often artistic in appearance, but seldom possess such valuable literary features as are found in the calender for 1889, just issued by the American Electrical Works, Providence, R. I. Heretofore, Mr. Phillips has often adorned his yearly reminder with dainty engravings of more or less (usually more) attractive objects; this year he goes a step further, giving on each weekly leaf of the calendar an apt quotation and a number of references to historical incidents the anniversaries of which fall within the week. The quotations are from writers of all periods, including some from the Hebrew scriptures, and relate either directly or indirectly to electrical science or the arts founded upon it. The historical memoranda, some 200 or more in number, include the dates of the notable events in the course of electrical development, from the earliest notices of the existence of the mysterious force to the modern applications of it in the arts of the world. Both quotations and notes have been prepared by a skillful hand directed by a nimble wit, and they are not less entertaining than useful. The compiler has made use of much out of the way information, and supplies many facts and dates not readily accessible to the general reader or student.

The calendar will doubtless be much sought for. It is well worth careful preservation for occasional reference.

NEWS AND NOTES.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF DECEMBER 18, 1888.

THE Institute of Electrical Engineers met at the College of the City of New York, Tuesday evening, December 18. The meeting was called to order by the secretary, Mr. Ralph W. Pope, and, on motion, Mr. Geo. M. Phelps was chosen as chairman for the evening.

As previously arranged and announced, the session was devoted to a paper by Mr. W. J. Jenks, member of the Institute, director of the standardizing bureau of the Edison Electric Light Co., on "Six Years Practical Experience with the Edison Chemical Meter." (For Mr. Jenks's paper, see page 7.)

DISCUSSION.

The Chairman—I am sure the Institute is to be congratulated on the lecture this evening, and that we should be very grateful to Mr. Jenks for the pains he has taken and the elaborate preparations he has made, and for having given us a great deal of information, which probably few, if any, of us had, as to the practical experience with these electrolytic meters. It seems a very good practice, promising well for the future, that men who actually know about these things, and can therefore tell us all about them, should come before us and tell just what has been found out about them through experience. The subject is now open for discussion.

Mr. Jenks—I would like to say a word just at this time. It certainly is a good practice to bring people who handle devices of this kind into such a position as will enable them to tell what they know about such devices; and my regret, to-night is, that for several years, I have not done anything in the way of practically handling the Edison meter. I am not a chemist; and have, in a measure, gotten out of the way of handling or remembering figures and exact quantities about which you might ask me a great many questions that I should not be able to answer off hand. I have undertaken to show the practical results attending the operation of the meter, and any question in that line, as well as in others, that I chance to know about, I shall be very glad to answer.

Mr. C. S. Bradley—I would like to call Mr. Jenks' attention to the fact that he did not fully summarize the smallness of the error due to the comparative resistance of the bottle and spool, combined with the shunt. The ratio being as 975 to 1, there is a very small error.

Mr. R. W. Pope—I feel that I may congratulate myself somewhat, on being responsible for bringing up this subject. It was originally my desire to have some one take up the whole meter question, and go through it exhaustively, showing the work of different inventors. When I made this suggestion, I had no idea of the practical perfection attained in the Edison meter, nor of the multitude of devices which the inventor had brought out before arriving at the perfected form now shown us. We have seen that Mr. Edison has utilized the various properties of the electric current in many different and very ingenious ways. Many of these experimental meters may not be practical; but I am sure they all tend to show remarkable fertility of invention.

It has been very interesting to compare the experience in electric meters with those used for other purposes which have had discredit thrown upon them (and I think—rather unjustly). I have had some experience with the gas meter, and I must say, that I have always found it very accurate. I used to read one in the Western Union building. True, it was not used very much in the summer, but it ran on for four or five months, and the bill would come in for perhaps 25 cents. Once in a while the bill would be larger than the average and upon investigation I would find that some one had been working at night. I have a meter in the Institute office, and frequently use gas on dark days. My bill for six months was $1.47—not very exorbitant. There is an important point about the electric meter. It is going into a field where there has been nothing of the kind before, and that is power service. All power service is now furnished under contract, so much a year, or so much a month per horse-power; but there is always a question whether a man gets 6 h. p. or 10 h. p., whatever the understanding may be, and many judge by the width of the belt, and the tightness of the belt, as to how much the customer is taking. Then again, a man may pay for 6 h.p. in one day and not use it at all. In printing offices the presses may be idle all day, but they have to pay for their power all the same. In this field a meter should prove a very desirable instrument, and relieve the minds of many consumers as to the amount of the bills they ought to pay. Then in domestic service, we can all see the benefit of using a meter. For a residence, the contract service will not answer at all. So far as I know, the contract price at which incandescent lamps are put out precludes their use in private families, where that light is most desirable.

I could not help thinking, when I saw the pictures thrown upon the screen, as they passed one after the other, what a long road Mr. Edison had traveled over, and how much trouble he might have saved, if he had only permitted himself to be guided by the experience of John Gilpin, who rode through Cheapside,

> And hung a bottle on each side
> To make his balance true.

Mr. Edison has got his meter down to two bottles, and we have been shown to night that the instrument is true.

Professor E. L. Roberts—I would just like, if Mr. Pope will allow me, to take one of his remarks as a text, for a moment. It was about the gas meter. We had an electric light company in Cheyenne, and I blackguarded the gas meter with all my power. Then, we bought up the gas company. I had to send bills to the gas people, and the customers remembered it, and it was a difficult thing to get out of. When I went to prove up the meters, one of them registered in favor of the company; nearly everyone was in favor of the consumer, about three per cent., and some considerably more than that. As the tendency of the electric companies is to buy up the gas companies, and not the gas companies to buy up the electric light companies, it is not advisable for any man to get into that fix, if he can possibly help it. I would like to ask the lecturer if there is any basis as to the length of time to weigh up and do all the registration necessary, say, on 100 meters—the time required to do the manipulation necessary to arrive at the figures.

Mr. Jenks—I think, perhaps, a fair approximation to that may be reached by the averages which were given on the number of meters per station, and the average expense. The number of meters per station on an average, in 18 stations being 225, the average expense being $4 per meter per year, it would make a 225 meter station cost $900 a year, in the man and chemicals, and everything else required. In other words, a station of that kind would represent just about that amount of running expense after the plant had once been installed. There are several records of one man attending to a great many meters; but I think, perhaps, experience has shown that men vary in their ability to do that sort of work just as they do in the trimming of arc lamps, or

anything which requires care, and at the same time, rapid manipulation. I should be very glad to bring out somewhat more definite data in reference to that.

Professor. Roberts—Who does that work, the bookkeeper?

Mr. Jenks—That depends to a considerable extent on the size of the station. In a very small station, say a 1,000 light station, the superintendent does his own meter work, and can do it without any difficulty. There are two or three superintendents now, some of the oldest men in the Edison business, who, with 2,000 lamps installed, take in the bottles and replace them themselves. When the station gets a little larger, a boy is employed to do that merely mechanical work. Then the time comes when the motor man, who should be an intelligent man, does simply the weighing, and all the other mechanical parts of the business are done by a large number of people. Then, instead of making out the bills himself, he simply sends the weights to the bookkeeper or the superintendent: so it comes that we have all the way from, we might say, one-half to 3 and 4 or 5 men employed in the motor business, according to the size of the station.

Dr. Schuyler S. Wheeler—Mr. Jenks, in describing the 3-wire meter, omitted to explain the way in which the two sets of bottles took care of the 3 wires. I would like to call his attention to that. The current, in going out on the positive wire, for instance, is registered in the positive bottle. It may return through the neutral wire, and it may return through the negative. In that case it is registered in the negative bottles. After returning on the neutral wire it is registered again. The passage of the current through this wire causes it to consume another 110 volts, so that it should be charged up twice.

Mr. Jenks—I neglected to make it plain that the neutral wire acted as a compensation for the meter, as well as for the line service.

Mr. F. B. Crocker—I would like to add a word or two to what Mr. Roberts said about the general accuracy of meters, and the particular accuracy of electric meters, or inaccuracy, if people prefer to put it that way. The meter is synonymous with fraud in the popular mind. But, I think, it is more a question of human nature than anything inherently bad in the meter. The gas meter, as Mr. Roberts said, would probably, if tested in New York, be found to be in favor of the customer in at least three cases out of four; and in the case of large errors, they would almost always be in favor of the customer, for the reason that the gas meter is a gas engine; it is worked by the gas, and the gas must flow through in order to work the meter. Now the gas may flow through and not work the meter, if the meter is stuck, or the friction is great, or there is any other fact about it that is antagonistic to the proper working of the meter. Now, something the same is true of this Edison meter (that the electric current operates the meter, therefore the current must flow in order that the meter shall record). On the other hand, the current may flow without fully recording its value. For instance, if the contacts are all in the meter circuit, why the friction of the current that should pass through the meter will not pass through the meter, and it is possible that no current at all will pass through it, and yet a large amount of current be used in the house. In fact, in any meter it is almost always the case that the current is much more apt to flow, or a commodity, whatever it may be, gas, water or electricity is much more apt to flow and not record than that a record can be made without any current passing. And I think that fact is forgotten when people condemn meters; because the very nature of the apparatus necessitates that whatever is measured shall pass through in order that it may be recorded. Now, as to whether the company simply reads one thing, and charges for another, of course, has nothing to do with the meters. It is entirely outside of the theory or practice of meters; it is merely a question of pen and ink. But I think the meter is as accurate as any other practical instrument, and I think that gas is measured as accurately as cloth or milk.

Mr. Pope—Or coal.

Mr. Crocker—Or coal, or any other commodity that is furnished to the public as measured. And the fraud, if it does occur, and I suppose it does in some cases, is a case of deliberate fraud where the method and apparatus for making the measurements may be perfectly correct; and it is after the meter has done its work that the bookkeeper puts the increment on to the people, which the meter has to take the discredit for. There are so many more people who talk against meters than are in favor of them, that I think a word said now and then on the other side is no more than fair.

The Chairman—Perhaps the gas companies will at last find some cause to be grateful to electricians in the way the veracity of meters in general has been maintained to-night.

Mr. Howell—There is one point in the criticism which Mr. Jenks quoted from the past proceedings, which, I think, ought to be mentioned. That criticism was about as follows:—You are measuring only a very small proportion of the current which you are selling, that is a 975th part, and any error in the measurement is multiplied by 1,000, practically. Well, that is true, and yet it is not true. Although we measure a 1,000th part of the current, and multiply by 1,000, any error in the measurement is not multiplied. If we measure 1-1,000th part of the current, and multiply by 1,000, any error in that measuring bottle or in the resistance of the circuit in which the measuring bottle is placed, is multiplied by 1,000; but the percentage of the error is always the same, and if we have an error of 10 per cent. in the circuit in which the bottle is it means an error of 10 per cent. only in the result. No matter what kind of meter it is, whether that bottle is in the main circuit or in the shunt circuit, a 2 per cent. error would be a 2 per cent. in every case, and it would not be multiplied by 1,000 in one case, as the criticism would lead you to believe. I have watched the introduction of the Edison meter, in one place especially, and I have watched its growth from the very beginning. When the Edison meter was first put into stations the first thing a man asked was, "Is the Edison meter accurate?" And, really, there was, for some time, a diversity of opinion among the Edison people as to whether it was really an accurate meter. But the experience of the users of the meter has been so gratifying, and it has been so much to the credit of the meter, that you very rarely hear the accuracy of the Edison meter questioned to-day; in fact, among the Edison electric light people it is not questioned at all. It is known that the experience of the people using it for the last 6 years has shown beyond question that the Edison meter is accurate. The station I spoke of is the station at New Brunswick, N. J., which started out not to use any meters. They would make a contract with the consumer, and give him such light as they thought he would burn at a fixed rate. The more they used that system the more they were convinced that they were only getting about one-third as much for their current as they supposed they would get. To overcome that they introduced the meter, and the result of changing from the contract to the meter has been a very much diminished output from the station, and a very much increased revenue. They get twice as much in return for a given output of electricity as they did before. The accuracy of the meter at New Brunswick has been checked several times by the customers counting their lamp hours. I have never heard of a case there in which the customer got the best of the meter; I mean in which the meter was found to be wrong. My belief, and the universal belief in the Edison meter, is the result of experience with it.

Mr. F. R. Upton—I would add a word from my own knowledge of the very long course of experimenting that Mr. Edison went through to obtain the results that we now have. In the early days at Menlo Park, these various forms that have been shown on the screen were made and tried. I realize very fully, the difficulties in making any mechanical meter, or any meter that will not stick at starting. I think that those who have given attention to the meter can hardly have failed to anticipate that trouble, except with a chemical meter. In meters that use the heating effect, as we have been shown, the sticking of the meter is an uncertain quantity, and is invariably against the company; those meters will never be used. If the error were in favor of the company, I have no doubt they would be largely used, but they are invariably against the company. The Edison meter is formed with the zinc plates instead of copper plates, which were first proposed. That represents a large amount of work at Menlo Park, and again at the Edison machine works, in Goerck street; and since then, Mr. Jenks has given an immense amount of time to it, so that it has to-day, been built up into an instrument of most thorough accuracy.

Mr. Edgar (of the Edison station, Boston)—We are using about 800 meters, and I have the utmost confidence in them. I have tested a great many, and I have had our customers test them for us. I have known of numbers of cases where they have proved within one per cent., and I never have known of a case where we had to retreat from the position that the meter was correct. We have a large number of meters, and are able to determine exactly the horse-power hours per month of each meter; thus being able to make a contract price in the next case, which would be more satisfactory than if we had not made those tests.

One gentleman asked a question to-night, as to the cost of meter service. We have 800 meters. In that department there are five men; three of them are, practically, boys who go around town collecting bottles. We extend over a territory nearly three miles from one extreme to the other. The fourth man does the weighing, and the fifth man makes out the bills and sends them up to the bookkeeper, ready to be mailed; so that we really do more in the meter department than is usually done in a department of that kind. It costs, perhaps, $2,500 a year to take care of the work of our 800 meters. A great many, as I have said, are on motors where we are experimenting, making changes once a week, so as to get at a fair average for different classes of work.

Mr. Howell—I suppose everyone here knows that there has been a great deal of inventive energy wasted on meters. The records of the patent office show an enormous number of mechanical meters, and I think the Edison company have had about as many presented to them as anybody has. The great point in favor of the Edison meter, as compared with any other, is its cheapness. If we want to equip a station with 800 meters, like Mr. Edgar's station, it makes a very great difference whether we have to pay for a complicated mechanical contrivance, which is necessarily expensive; or whether we have to buy a box with a couple of pieces of german silver and two bottles in it. The element of

first cost is a very significant factor in favor of the Edison meter. You can pay for your meters almost as much as you would for the station itself. A successful meter must have two qualities: it must be good, and it must be cheap; and I think, the Edison meter has those two qualities very preeminently.

Professor Roberts—As to mechanical meters, it is an open question whether we cannot some day arrive at a mechanical meter which will be satisfactory. So far as cheapness is concerned, certainly, a Waterbury watch is as cheap as these two bottles and two pieces of german silver, yet there is a great deal of mechanism in it. I wish to bring up one point showing how the customer, if he finds any expense kicking up against him, will want to economize. A station I know of has a 12″ by 36″ Corliss engine. The lamp renewals were paid for by the company, and the lighting done by contract price, and everything was running beautiful; the engine was supposed to be developing about 65 h. p. (the indicator card showed about 100 h. p.) from 6 o'clock in the evening to about 10; then it dropped down somewhat. The charge for a new lamp was about 75 cents; the customer expected it was to burn about 1,000 hours. As soon as he got a bill the indicator card showed that the engine was developing 75 h. p. instead of 100. Therefore, they saved over 25 per cent. of power just as soon as the customer felt that the lamp breakage alone was being charged against him. I do not doubt that the gentlemen who have employed both the contracting and the meter system can show even more remarkable figures than these.

Mr. Brown—Into the construction of this meter there entered one material on which there has been considerable discussion during the last year, namely, german silver. It, perhaps, will not be out of place to inquire whether they have any special standard of excellence for german silver at the Edison laboratory.

Mr. Jenks—As I said in general, in the description, the best german silver that can be obtained is used, that is to say, a quality equal to that employed in making bridges is used in the metal shunts. Of course, the standard, so far as the construction of each individual meter is concerned, comes in the resistance, and that resistance has to be determined to within a very minute fraction of an ohm in the placing of the strip in the box before it can be standardized.

Mr. Evirt—I happen to know that the german silver used in the Edison meter is 18 per cent. german silver, and it gives a little better temperature co-efficient than that quoted in books, I believe. It is said that some electric light men are very prone to mix what has been done with what is about to be done. I want to say that Mr. Jenks has been extremely conscientious in describing the Edison meter as it has been, and not as it is about to be. No changes of a radical nature have been made in it since it was first introduced. I may say that there has been practically concluded now a series of experiments on the meter, and the company are getting ready to offer a new meter which will be a great deal better in many respects, *i. e.*, in the cost of the meter, in the decreased cost of operating, and in the much less strain on the meter man's back. It appears to us that, given a spool with a piece of german silver, the Edison meter depends on the laws of electrolysis and chemical balance; and the chemical balance is probably the best and most reliable and most sensitive instrument known. So it appears to us that we do not need any large quantity of zinc to weigh or to carry about, and we propose to reduce it to one-half, in some instances to one-fourth, and in some instances to one-eighth, so that the box will be about half the size it is at present. The bottle will be half its present size. In place of two bottles there will be one bottle. We will call on the balance for the accuracy we can get out of it, and call upon the meter man for a little more pains.

The Chairman—Are there any other speakers? Although the hour has arrived and gone by when we usually adjourn, there is an opportunity for further remarks. The secretary has some announcement to make, I think.

The Secretary—I have to say that in view of the approaching International Exhibition at Paris, several engineering societies here have received invitations to participate in meetings held by various similar societies abroad, and the Institute has received two letters, one from the Institution of Civil Engineers, and one from the Society of Arts, in London. I wish to read these, and bring to your attention the arrangements which are being made by the Society of Mechanical Engineers for an excursion to Europe.

The secretary then read the communications referred to.

THE INSTITUTION OF CIVIL ENGINEERS,
Established 1818.—Incorporated by Royal Charter, 1828.
25 Great George St., Westminster, S. W.,
November 23d, 1888.

To the Secretary of the
American Institute of Electrical Engineers,
New York City, U. S.

Sir—It is reported that many engineers from the United States will probably visit Europe during the International Exhibition which is to be held in Paris in 1889.

In view of this, the council of the Institution of Civil Engineers, at the first meeting of the present session, directed an inquiry to be addressed to you to ask: 1st. Whether this report is correct, and, if so, whether your Institute can give any idea of the number of your members likely to come. 2d. Whether they will travel by way of England; and 3d. What may be expected to be the approximate date of their arrival, and the duration of their stay in this country.

The object of this inquiry is to enable the council to consider the possibility of making such arrangements as may best tend to further the objects which the visitors have in view, and to render their visit as useful and agreeable as possible

The council need hardly assure you of its good will toward its professional brethren in the United States, and of its desire to embrace this opportunity of manifesting its friendly feeling to the utmost of its power.

Of course, in any case, the facilities afforded by this Institution are always at the disposal of your members.

We are, yours faithfully,
GEORGE B. BRUCE, *President*,
WILLIAM POLE, *Hon. Secretary*,
JAMES FORREST, *Secretary*.

SOCIETY OF ARTS,
John Street, Adelphi,
London, W. C.,
December 8th, 1888.

Sir—The council of this society have been given to understand that a visit of American engineers to this country during the spring or summer of next year is in contemplation.

The council will be very glad if the Society of Arts can in any way facilitate the visit of your members to England, or render their stay here more pleasant. They will be glad to place the rooms of the society at their disposal; and if their visit should coincide with the society's annual conversazione in June, they will be very pleased to see as guests on that occasion such of your members as may be able to attend.

We have the honor to be, sir, your obedient servants,
ABERCORN, *Chairman of Council*,
H. TRUEMAN WOOD, *Secretary*.

The Secretary of the
American Institute of Electrical Engineers.

The secretary read also a circular issued by the American Society of Mechanical Engineers, announcing a projected excursion of engineering societies to Europe during the French Exhibition, including the following information :—

DATES.

Minimum absence, five weeks. From last week in May to first week in July.

COST.

Round trip passage by steamer, $110, going altogether in a body and returning individually at any time during the year, as may be convenient. Cost per day per person on shore from $4.00 upward, according to personal ideas.

The trip will begin soon after the adjournment of the Erie City Convention of the Mechanical Engineers.

The Inman Line will reserve for our party either the steamer City of Richmond or the City of Chester, giving us the entire first cabin for our exclusive use, provided we will guarantee 150 persons, including the ladies, at the above rates. By having our own steamer, the sailing day may be fixed to suit our convenience, to say nothing of the social advantage of being by ourselves and in control of the ship.

The secretary said further—About a week after the circulars of the Mechanical Engineers were issued by secretary Hutton, I was informed that they had already received affirmative responses from 75 members; so it appears probable that the arrangement for a special steamer can be carried out. I am in negotiation with Mr. Hutton now in regard to the preparation of our own circulars. I bring it up to-night in order to give you this information in advance, to guide you in arranging for your vacation, and to induce you to save your money meanwhile.

The next meeting of the Institute for the discussion of papers will be held on Tuesday, January 8th. The subject of the paper will be "Lightning Arresters, and the Photographic Study of Self-Induction," with numerous illustrations and experiments, by E. G. Acheson, member, electrician of the Standard Underground Cable Co.

RULES AND REGULATIONS FOR OVERHEAD CONDUCTORS FOR ELECTRIC LIGHT AND POWER.

Adopted November 13, 1888, and Promulgated by the Board of Electrical Control of New York.

I. No two lines of poles bearing conductors of a like class shall be erected on any street or avenue.

II. No two lines of poles shall be erected on the same side of any street or avenue.

III. Poles shall be set in the sidewalk twelve inches from the outside of the curb, and no pole shall be placed within ten feet of any lamp post or other pole, except at street corners where necessary in order to support wires running on the cross street.

IV. All poles now standing, or to be hereafter erected, shall be branded or stamped with the initials of the company owning them, at a point not less than five nor more than seven feet from the street surface; and when a pole is occupied by wires belonging to more than one company, each group of cross-arms, or where necessary the support of a single wire of different ownership, must be distinguished by some characteristic paint mark or fastening.

V. Electric light lamp-posts shall be in accordance with the plan adopted by the Board.

VI. All poles erected for the purpose of carrying lines of more than two electric light or power wires shall be at least forty-five feet high, uniform in size, straight and painted from top to bottom a very dark color from the sidewalk to a point eight feet high, and a dark green color above that.

VII. All poles for carrying not more than two electric light wires shall be twenty-five feet high, straight, uniform in size, and painted from top to bottom—a very dark color from the sidewalk to a point eight feet high, and a dark green color above that.

VIII. Cross-arms shall be uniform in length, strengthened by braces, and painted the same color as the poles; the cross-arms of each company being distinguished by some characteristic mark.

IX. Each line of poles must be run on one side of the street only, except when absolutely necessary to change to the other side; but this may only be done by the permission of the Board or of its engineer or expert.

X. Electric light conductors must not be placed upon fixtures erected or maintained for supporting wires of the other class, namely, those for signaling, except by permission of the Board.

XI. Poles shall be uniformly spaced, and about sixty to the mile. This requires on the short city blocks of two hundred and sixty feet, alternately three and two poles to the block.

XII. All conductors shall be secured to insulating fastenings, and covered with an insulation which is water-proof on the outside and not easily worn by abrasion. Whenever the insulation becomes impaired it must be renewed immediately.

XIII. No wire shall be stretched within four inches of any pole, building or other object, without being attached to it and insulated therefrom.

XIV. Every wire must be distinguished by a number plainly marked on each cross-arm under the insulator.

XV. No unused loops from electric light circuits shall be allowed to remain after lamps are taken away, except in cases where it is positively known that the lamp will be required again within three months, and where there is no underground conduit for that class of circuits.

XVI. All arc lamps must be so placed as to leave a space underneath of nine (9) feet clear between lamp and sidewalk.

XVII. All wires must be stretched tightly and fastened to glass or porcelain insulators, approved by the expert, with a strap of the same kind of wire.

XVIII. All connections with lines of electric light conductors shall be made at right angles to the same; and connections to buildings shall be run straight across to the building, and then down the front of the building.

XIX. All joints must be as well insulated as the conductors, and the insulation of joints must be maintained.

XX. Every line entering a building shall be controlled by a cut-off placed near the entrance, in sight, and easily accessible.

XXI. No wires shall hang within twenty feet of the pavement at the lowest point of sag between supports.

XXII. In the construction of lines the insulation to be used must be approved by the expert of the Board in writing, and the insulation resistance must be maintained in accordance with a standard to be not less than $\frac{1}{10}$ megohm per mile per hundred volts. And under no circumstances shall underwriters' wire be used.

XXIII. All circuits must be tested every hour, and when a ground comes on, effort must be made to remove it at once. Failing in this, the current must be discontinued until the insulation is restored.

XXIV. The insulation must be preserved throughout the entire circuit, and if any portion of a lamp or fixture is a part of the circuit and can be touched, it must be insulated.

XXV. All conductors shall have a resistance uniformly distributed of not more than 30 ohms per mile per ampere, and proportionately less for heavier currents.

XXVI. All existing regulations of the local authorities in regard to the placing of poles and stringing of wires are to continue in force, except when in conflict with these rules; and the rules and regulations of the New York Board of Fire Underwriters must be strictly observed.

XXVII. The violation of any of the rules and regulations of the Board shall operate *ipso facto* as a revocation of the permit held by the company or person guilty of such violation.

XXVIII. Whenever hereafter any company shall be permitted by this Board, or its successors, to erect posts or poles, or other fixtures bearing lamps or other devices, for the purpose of lighting by electricity the streets, avenues, highways, parks or public places of the city, the said permission shall be granted only subject to the following provisions, and the same is hereby expressly made a condition of said permits. At any time when, by action of the city authorities, the contract for lighting any such street or other public place shall be given to another company, the company erecting said lamp posts shall, on tender of the first cost thereof, yield possession and ownership of the same to the said other company obtaining the new contract, except in cases where the company owning the lamp posts prefers to remove them.

XXIX. All broken and "dead" wires, and all wires, poles and fixtures not actually in use—subject to rule XV—must be removed from the streets, avenues and highways of the city. When an old pole is taken down it must be removed from the streets the same day. New poles must not be brought upon any street more than two days in advance of their erection. Any pole that shall lie on any street more than two days shall be removed by the Bureau of Incumbrances of the Department of Public Works, at the expense of the party owning it.

XXX. From and after the first of January, 1889, no company shall do business of arc electric lighting in the City of New York without a certificate of the Board, granted on the recommendation and after inspection by the expert of the Board, to the effect that its lines comply with all the rules and regulations of the Board, and that its plant is in proper condition for the doing of its business. The force of the certificate to continue until changes are made, of which the Board must be notified and approve, or so long as the plant and conductors remain in the same condition as when inspected.

XXXI. Every lineman must wear a badge in a conspicuous place, giving his number and the name of the company by whom he is employed.

XXXII. All permits of the Board for overhead wires and fixtures are granted only pending the providing of underground accommodations in the neighborhood of the street or avenue for which the permit is granted.

XXXIII. Any member or officer of the Board, and every inspector employed by it, as well as every member of the police force of the city, shall be entitled to examine permits under which work of any kind is being done.

XXXIV. No permit shall be granted for the erection of any overhead structure nor for the renewing of any lines already existing in any street, avenue or highway in which underground accommodations for the service have been provided, or are being provided.

XXXV. Every line, pole, fixture, etc, must be kept in thorough order, repair, and conformity with these rules and specifications, upon penalty of forfeiture of all permits granted to the owner by this Board.

But the general permit under which these repairs are to be made does not cover the erection in any street, avenue or highway of any new poles or other similar fixtures, and has absolutely no reference whatever to lines which have been ordered underground by the Board, and which the Mayor has been requested to remove.

In the case of such lines, where notice has been given that underground accommodations have been provided, and the ninety days of notice required by law have elapsed, and the Mayor has been requested to remove the same, companies owning or operating said lines are not authorized to make any repairs or connections or to go upon the poles bearing such lines *for any purpose whatever*, except to remove the said lines of electrical conductors in conformity with the directions of the Board.

Any deviation from this rule requires a resolution passed at a regular meeting of the Board, attested by the secretary.

XXXVI. Every company or person erecting poles, wires or fixtures must make and leave, at least once each week, at the office of the Board, such records of the fixtures, etc., which they are erecting, and of all of the same that they have in use, as are required by the engineer and the electrical expert of the Board, and in such form as shall be prescribed by them.

XXXVII. The companies or persons owning or controlling poles in any street or avenue, erected under permits of this Board or the Board of Electrical Subways, shall allow the same to be used by other companies or persons operating conductors for similar electrical service when authorized so to do by the Board, on tender of proper compensation to be determined by agreement between the parties interested. In default of such an agreement the amount of such compensation shall be determined by the Board. This rule imports a contract on the part of each company or person owning or controlling the poles on any street or avenue, not only with the Board but also with each company or person who shall under its terms be qualified to demand the privileges it confers, to permit this joint use of poles.

And in accepting any permit the applicant thereby binds himself to this agreement.

POINTERS.

.... In the Central Savings Bank, in London, it has been found after two years' experience of electric lighting, that the average amount of absences from illness has been diminished by about two days a year for each person on the staff. This is equivalent to a gain to the service of the time of about eight clerks in that department alone. Taking the cost at the "overtime" rate only, this would mean a saving in salaries of about £640 a year.—*W. H. Preece.*

.... Few will be prepared to deny that pure electrical science has received an enormous impulse, and has been advanced by the commercial application of electricity to purposes of lighting.—*Sir Frederick Bramwell.*

.... It will not merely be for the inauguration of the quick transmission of our bodies by steam, or the quick transmission of our thoughts by telegraph, but for the economical transmission of power by electricity that the Victorian age will be remembered. —*Professor Ayrton.*

.... When that evil day arrives that our supply of natural fuel ceases, we may look to electricity to bring to our aid the waste energies of nature—the heat of the sun, the tidal wave of the ocean, the flowing river, the roaring falls, and the raging storm. —*W. H. Preece.*

MINIMIZING THE BANEFUL EFFECTS OF THE EXTRA CURRENT.

The injurious effects of the extra current of rupture in a circuit of considerable self-induction are of two kinds. The sparks which burst at the point of rupture (primary circuit of Rhumkorff's coil, brushes of dynamos, telegraphic apparatus, &c.), oxydize the contacts, increase the resistance, and reduce the useful effect of the current. From a physiological point of view, the danger of the extra current is still more serious, and may become deadly.

Various means have been proposed to lessen these effects: (1) a condenser employed in the manner of Fizeau (Rhumkorff's coil); (2) condenser in derivation between the extremities of the electro-magnet (relays and telegraphic apparatus); (3) rheostat in derivation on a dynamo (D'Arsonval, *Comptes Rendus*, January and March, 1885); (5) telegraphic lightning rod in derivation (Raynaud, *Comptes Rendus*, March, 1885), &c.

I purpose to show how the conditions of efficiency of these means may be submitted to calculation and expressed in figures. To this end we shall admit that for the suppression of these injurious effects the difference of potential at the extremities of the electro-magnet should not at any moment exceed a maximum, E, the value of which has to be fixed (100 volts, 200 or 500 volts, as the case may be).

1. *Rheostat in derivation on the electro-magnet.*—Let R be the resistance of the electro-magnet, I the normal intensity of the current traversing it, ρ the resistance of the rheostat, the self-induction of which may be overlooked. On the rupture of the exterior circuit the electro-magnet and its shunt form a closed circuit, in which the current sinks gradually from I to zero. The maximum difference, V, of potential at the extremities of the shunt, and consequently at those of the electro-magnet, cannot exceed $\rho\ I$. It results that the efficiency of the shunt will be secured if we take ρ less than $\frac{E}{I}$.

Example.—Morse electro-magnet ($R = 500^{\omega}$, $I = 1.015\ a$ = normal working current). If we wish that V should not exceed $E = 150^{v}$, we only need give the shunt a resistance ρ less than $10{,}000^{\omega}$.

If we take account of the very slight self-induction of the shunt, the result is not sensibly affected. The calculation would be too long to be developed here.

Voltameters in derivation.—We take voltameters of such a number that their maximum electromotive force, e, may slightly exceed the normal difference of potential, $R\ I$, at the extremities of the electro-magnet. Let R be their resistance.

On repeating the above reasoning, we find that the maximum difference of potential, V, at the extremities of the electro-magnet during the rupture cannot exceed $\rho\ I + e$, or approximately $(\rho + R)\ I$. If the resistance, ρ, of the voltameters is small, V will scarcely exceed the difference of potential, $R\ I$, of the normal condition.

By reason of their considerable capacity of voltaic polarization, the use of voltameters is suitable only in case of currents essentially variable (telegraphic transmissions, alternating dynamos, &c.).

3. *Condenser in derivation on the electro-magnet.*—Let R and L be the resistance and the self-induction of the electro-magnet, I the normal current, C the capacity of the condenser. On the rupture of the exterior circuit, the electro-magnet and the condenser form a closed circuit, in which the current, i, declines gradually from I to zero. This current, i, causes the charge $C\ v$, of the condenser to decrease, and consequently the difference, v, of the potential at the extremities. When the discharge is complete, if the intensity, i, is reduced to zero, the extra current comes to an end without v having exceeded the normal difference of potential, $R\ I$, the condition of efficiency is, of course, fulfilled.

This case occurs when C exceeds the value of $\frac{L}{4\ R^2}$ as a calculation in full would show.

But it may happen that when the charge of the condenser becomes null, the current has still an intensity, $i < I$. The charge, $C\ v$, continues then to decrease. v equally changes its direction, and reaches a maximum, when the current, i, becomes null. Then the condenser discharges itself anew, and thus in succession. This is the phenomenon well known as the oscillating discharge. The point is to keep V below the fixed maximum, E.

At the moment when the condenser is entirely discharged, the current having the intensity, i, the energy still to be expended is $\frac{1}{2} L\ i^2, < L\ I^2$.

Then, since the intensity, i, has fallen to zero, the energy still available is $\frac{1}{2} C\ V^2 < \frac{1}{2} L\ i^2$. Then, in order that V may be smaller than E, we must have

$$\tfrac{1}{2} L\ I^2 < \tfrac{1}{2} C\ E^2 \text{ or } C > \frac{L\ I^2}{E^2}.$$

This is a *sufficient* condition of efficiency; the *necessary* condition is obtained by a calculation too complicated for practice. We shall therefore adopt as the lower limit of the capacity C, the value $\frac{L\ I^2}{E^2}$ or the value $\frac{L}{4\ R^2}$ if this is lower than the former.

Example.—Electro-magnet Morse ($L = 10$, $i = 0.015\ a$), if we fix $E = 150$ volt we must take C greater than 10^{-7} farad or $\frac{1}{10}$ microfarad.

4. *Case of an intentional rupture of the circuit.*—We may break a circuit by introducing resistances increasing progressively up to infinity. The duration of such a rupture must not be less than $\frac{L\ I}{E}$ if we wish the electromotive force of self-induction not to exceed the fixed maximum E. The law according to which it is advantageous to introduce the progressive resistances is easily calculated.

The other means which have been proposed or which might be studied with a view to reduce the bad effects of the extra current may be calculated in an analogous manner.—M. VASCHY, in *Comptes Rendus.*

A NEW METHOD OF PROPELLING BOATS.

A successful trial trip was made this month from Brooklyn of Mr. John A Secor's yacht, "Eureka." The boat is propelled by the explosion of atomized petroleum which is ignited at intervals by an electric spark, the action being somewhat similar to that of a gas engine. The method, however, of applying this power is decidedly novel, the cylinder extending down into the water at the bow and stern, and large pistons pushing against the water at each explosion, thus propelling the boat forward. A larger boat is being constructed, and it is stated will be launched the coming spring.

A CONDITION OR A THING?

A telegram from Harrisburg, Pa., suggests the novel question whether electricity is a "condition or a thing." It says: Although philosphers have never been able to determine whether electricity is a condition or a thing, a case will be tried by the courts of Dauphin county next month in the hope of throwing light on a very ancient dispute. Under the act of 1885 manufacturing companies in Pennsylvania, with few exceptions, are exempt from taxation. The state authorities have refused to recognize electric light companies as manufacturers, and several of these corporations have appealed from the settlement of the tax which the commonwealth has imposed upon them. The novel point to be decided is whether or not electricity is manufactured.—*Light, Heat and Power.*

BOSTON STREET LIGHTING CONTRACTS ATTACKED BY THE CITIZENS' ASSOCIATION.

The executive committee of the Citizens' Association of Boston, Mass., presented a communication to the city council, under date of November 19th, drawing attention to the existing contracts between the city and the several electric light companies under which the city is paying at the rate of 65 cents each per night for arc lights. This price, the committee claim, is excessive, and in substantiation thereof submit figures which they have received from the authorities of several large cities. In all of these cities, it is claimed that the standard of measurement of candle-power, and the number of hours which the lights are kept burning, and all other conditions, are similar to those prevailing in Boston. The figures given by the committee are as below :—

Cities.	Date.	Lights.	Cents.
Albany, N. Y.	Not given.	481, at	.50
Baltimore, Md.	"	519, at	.50
Brooklyn	July 2, 1888.	1014, at	.50
Buffalo	Nov. 16, 1888.	996, at	.45
Fall River, Mass.	Not given.	260, at	.55
Fayette, Ind.	"	207, at about	.26
New Orleans	June 13, 1888.	822, at	.34
New York	June 12, 1888.	1435, at	17½ to 35, Average 34½
Philadelphia	June 13, 1888.	756, at	47½ to 55, Average 50
Providence, R. I.	Not given.	295, at	.50
Scranton, Pa	"	212, at	.20
		100, at	.35
Syracuse, N. Y	"	280, at	.39
Troy, N. Y.	"	392, at	.48½
Utica, N. Y.	"	375, at about	.30

The existing contracts were made for three years, and terminate on January 7th, 1890; but the committee claim that they are clearly illegal on the grounds that the city charter provides that "no expenditures shall be made nor liability incurred beyond the appropriation duly made therefor," and also because "it is doubtful whether a city council has a legal right or power to bind its successors for any term of years indefinitely."

It was brought out in the course of the discussion upon the petition, that at the time the contracts were made, several other cities, notably New York and Baltimore, were paying considerably

more for this service than 65 cents per light per night; and it may be noted in connection with the figures given by the Citizens' committee as the cost of lighting in other cities, that these figures differ somewhat from those furnished by others.

THE WESTERN UNION TELEGRAPH COMPANY.

REPORT FOR THE QUARTER ENDING DECEMBER 31, 1888.

Executive Office,
Western Union Telegraph Co.

New York, December 12, 1888.

The following statement exhibits the condition of the company at the close of the quarter ended September 30, 1888 :—

Surplus, July 1, 1888, as per last Quarterly Report.		$7,498,548.94
Net revenues, quarter ended September 30, 1888...		$1,707,378.94
		$9,205,927.88
From which deducting for—		
Dividend of 1¼ per cent. paid Oct 15...	$1,077,376.89	
Interest on bonded debt	184,802.08	
Sinking funds........................	19,991.00	
	1,282,169.97	
Left a surplus October 1, 1888, of.................		$7,923,757.91
The net revenues of the quarter ending December 31st, instant, based upon nearly completed returns for October, partial returns for November, and estimating the business for December, will be about......		$1,650,000.00
Add surplus, October 1, as above.......		7,923,757.91
		$9,573,757.91
From which appropriating for—		
Interest on bonds...	$184,802.08	
Sinking funds.........................	20,000.00	$204,802.08
Leaves a balance of		$9,368,955.83
It requires for a dividend of 1¼ per cent. on the capital stock		1,077,376.89
Deducting which, leaves a surplus, after paying dividend, of.....................		$8,291,578.94

The gross receipts for the quarter ended September 30, were $5,305,703.25, being an increase over the corresponding quarter of last year of $458,157.33. The expenses were $3,598,324.41, showing an increase over the same quarter of last year of $57,689.70.

In view of the preceding statements, the committee recommend the adoption by the board of the following :—

Resolved, That a dividend of one and one-quarter per cent. on the capital stock of this company be hereby declared payable on and after the 15th day of January next, to stockholders of record at the close of the transfer books on the 20th day of December, instant.

Resolved, That for the purpose of the dividend hereby declared, the stock books of the company be closed at three o'clock on the afternoon of the 20th day of December, instant, and be reopened on the morning of the 2d of January next.

The resolutions were adopted by the board of directors.

Respectfully submitted,

NORVIN GREEN, *President.*

A CABLE TO AUSTRALIA via VANCOUVER.

The Earl of Winchelsea and Nottingham presided at Cannon Street Hotel, London, early in December over a very influential meeting of merchants and other gentlemen interested in the Canadian and Australian Colonies. The meeting was convened chiefly in support of the scheme for laying duplicate lines of cable to Australia *via* Vancouver. Lord Winchelsea said the advantages of the Pacific route were numerous and obvious. It was especially safe in times of war, and thousands of miles of it would be actually in British territory. When they commenced business the maximum rate would be 4s, compared with from 9s to 10s charged by the existing companies. They wished for no subsidies. All they asked of the various Colonial Governments was that they should use the new cables to the extent of £75,000 per annum. The cable, however, was only part of their scheme, which included two lines of steamers—every vessel fitted as an armed cruiser. They must remember that in case of war troops could be concentrated at Vancouver and landed thence in India or Australia with ease. Resolutions in support of the scheme were carried, the speakers including Sir Donald Smith and several prominent Australian colonists.—*The Engineer and Iron Trade's Advertiser.*

THE TELEPHONE.

The Paris-Brussels telephone line, the prime cost of which was covered by the first year's receipts, now yields some £4,800 per annum. It will be remembered that the Van Rysselberghe system is used on this line; and since the line is of phospor and silicium bronze it gives satisfaction. It is also claimed that much of the success attained is due to the Dejongh telephones which are employed.

ELECTRIC LIGHT AND POWER.

THE NEW YORK UP-TOWN STATIONS of the Edison Illuminating Co.—Service from the 39th street station was begun Thursday evening, December 27th, current being supplied to the lamps already placed in the Union League Club House. The two stations planned for the up-town service in 22d and 39th streets are very nearly completed, and ground has been bought for a third station in 53d street. The two very substantial and well appointed station buildings already erected will have a capacity of 35,000 to 40,000 lamps each when fully equipped. The electric light will, therefore, soon be available for residences throughout a large portion of the city, including the finest residence district.

PITTSBURGH, PENNA.—The contract for the city lighting has been awarded to the East End Electric Light Co. at $110,592 per annum. The plant will comprise 400 arc lights of the Waterhouse system, and 4,287 incandescent lights of the Westinghouse system. The bid of the Fort Wayne Jenney Company was $119,035.50. The East End Electric Light Co. have filed approved bonds for performance of contract and protection to the city from infringement suits in the sums of $25,000 and $50,000 respectively.

THE HEISLER ELECTRIC LIGHT CO., of St. Louis, has received an order for a central station plant for Michigan City, Indiana, which is expected to be completed and in operation before the first of January.

TESLA MOTORS.—The experiments conducted by the Westinghouse Electric Co. during the last three months with the Tesla motors are reported to be most satisfactory. A form has been perfected that will operate on the existing alternating circuits for the running of fans and other light machinery, and also the large motors for street car purposes and power purposes generally have been brought to a high degree of perfection and efficiency.

THE HEISLER COMPANY, of St. Louis, have already shipped the dynamos for the plant recently ordered by the Puebla Gas Light Co., and the work of construction is now going forward at Puebla. This plant will include street lighting as well as commercial and private lighting. Some 15 miles of line circuit will be required for the work laid out by the Puebla company. Armington and Sims and Ball engines will be used.

THE JULIEN ELECTRIC CO. report sales of 2,130 accumulators for the month of November, and 750 for the first 12 days of December.

Foreign.

Australia.—The Sandhurst-Eaglehawk Tramway Co., Melbourne, has ordered storage battery cars for its road, designed by Mr. Reckenzaun. The speed is to be five miles an hour up gradients of one in 20, and on the level eight miles an hour. The cars are provided with two 8 h. p. motors, worked from a battery of 72 storage cells.

England (London)—At a meeting of the court of common council, held at the Guildhall, the chairman of the city commission of sewers stated that they had taken the advice of Mr. W. H. Preece, and of Col. Haywood, their engineer, and that an agreement had virtually been come to regarding the manner in which tenders for the electric lighting of the city should be invited. It was stated that every important electric lighting company would be asked to tender.—The action of the Metropolitan Electric Light Co. in giving the order for their first central station to the Westinghouse company, has caused some dissatisfaction on the part of English contractors; but this feeling is likely to subside now that tenders for a second station have been invited on the understanding that an English firm will receive the contract. The Metropolitan company will thus be in a position to test by actual practical work whether the American or some English system of lighting is the best, and future orders will be given out according to the results of this test. The tenders now invited are for the whole of the generating plant (steam and electrical) required for the supply of 10,000 lamps, and for the transformers, but not for the mains.—*Industries.*

France.—THE PARIS MUNICIPAL ELECTRIC LIGHTING STATIONS.—The 25th and 26th of October, were the dates fixed for opening the tenders for the steam and electrical plant required in this installation. Eight firms have tendered for the electrical plant, viz., La Société Continentale Edison; La Société Lyonnaise; La Société Alsacienne; La Société d' Eclairage Electrique Jablochkoff; M. Patin, the representative of Mr. Ferranti; M. Victor Popp, the representative of the Thomson-Houston company, and M. Cuenod-Sautter. After inspecting the tenders of these parties, a sub-committee, under the presidency of M. Mascart, was formed, and instructed to examine the rival schemes in detail, and recommend one for adoption. The final decision is expected in December.

France.—CENTRAL STATION LIGHTING.—The Continental Edison Company are establishing a small central station in the gar-

dens of the Palais Royal, from whence current will be supplied to the Théâtre Français, and to the large shops immediate in the vicinity. The capacity of the station will be about 1,500 lamps. Several of the shop-keepers in the neighboring streets have applied to the company for current; but as they could only be reached by underground conduits, special permission from the municipal authorities is required, and this question was brought before the Council at their last meeting, but without effect. At the same meeting it transpired that none of the tenders sent in by electric light firms for the installation at the "Halles" was in complete conformity with the regulations laid down by the commission. No tender has consequently been accepted, and there are not wanting critics who affirm that the delay in getting to work is simply due to the fact that many of these regulations as contained in the *cahier des charges* are impracticable, and must be modified before contractors can accept them. This means more commissions and reports, and if things go on at the present rate there is no chance of the Halles installation being ready by the time the Exhibition opens.

Germany.—The central station in the Markgrafenstrasse, Berlin, is now being enlarged by the addition of four dynamos, each having an output of 100 kilo-watts. These machines have been made by Messrs. Siemens on their new plan, with internal field magnets, the armatures being of very large diameter, and coupled direct to the steam engine. The engines are of the vertical compound tandem type, and have no fly wheel except the armature. To save room, the crank shaft has been placed low down, and a pit has been provided in the foundation, within which the armature revolves. Owing to the large size of these machines, it was not considered advisable to finish them completely in the factory, and the armatures have been wound *in situ*. Similar machines are already at work at the railway station at Frankfort-on-the-Main. In addition to the two new central stations projected for Berlin, there will be erected a third station, bringing up the total capacity of electric lighting plant to 18,000 h.p., capable of supplying 200,000 lamps, which is about one-quarter of the total number of gas burners fixed in Berlin. The present capacity of the two existing stations is 3,800 h.p. In the future it is proposed to use for central station lighting steam engines of 1,000 h.p., instead of the present unit of 300 h.p., in order to reduce the proportional cost of attendance. All the manufacturers of glow lamps are busy, and are hardly able to fill the orders they have received for the present season. In many cases works are being enlarged, and the company making the Seel lamp are not only extending their manufactory to three times its present size, but are also projecting the erection of branch factories in Germany and abroad. A demand has lately arisen for lamps of high voltage, and several manufacturers have already made experimental lamps for 150 and 200 volts. In no case was the lamp found good enough for practical use. The general defect of all these lamps is that the thin filament is either broken from purely mechanical causes, or when heated by the current, bends and touches the glass, with the result of causing the latter to crack.—*Industries.*

ELECTRICAL SOCIETIES.

THE BUFFALO ELECTRICAL SOCIETY.—The Buffalo *Sunday Journal*, of December 16th, contains portraits of Messrs. Frank Kitton, Astley C. Terry, Geo. H. Usher and William Finn, together with a biographical sketch of each. The Buffalo society is one of the oldest of its class, having been organized September 11th, 1883, by several prominent telegraph operators. They have kept abreast of the development of electrical industries by mutual inquiry and discussion, and their meetings have proven of interest to electricians generally.

THE MISSOURI ELECTRICAL SOCIETY have adopted the following plan for the mutual instruction of members. A query box is provided into which can be deposited any question upon which a member desires information. By this means any embarrassment a member might feel in asking a question openly is obviated. Should the answers given not be sufficiently clear the matter can be followed by further inquiry. This plan is worthy of commendation by other similar societies for the benefit of the younger and less experienced members.

PERSONAL MENTION.

MR. A. NOLAN-MARTIN, M.A., F.S.Sc., formerly of London, Eng., is associated with Dr. Paget of the Macraeon Storage Battery Co., 7 Wall St., New York, as consulting electrician and analytical chemist.

MR. R. H. SOULE, formerly superintendent of motive power and general manager of the N. Y., L. E. & W. R. R., has been appointed general agent of the Union Switch and Signal Co., and is, among other duties, to have charge of the sale and introduction of the Westinghouse buffer referred to in our manufacturing and trade notes.

MANUFACTURING AND TRADE NOTES.

THE COMPOSITE CELL CO., D. C. Hood, general manager, have opened an office at 35 Broadway. They manufacture a composition cell for batteries, which they claim is acid proof, and of entirely new and indestructible material.

THE ELECTRO-DYNAMIC CO., of Philadelphia, Penn., has received the contract for lighting the Brooklyn Navy Yard, on their bid of $3,100.

THE ENO STEAM GENERATOR CO., 102 East 12th St., New York, have recently placed on the market a new steam generating system that is highly spoken of by mechanical engineers as well as by their patrons. The generator proper, consists of a series of pipe flues, each flue being composed of an inner and outer tube, the water being between the tubes. No coils or return pipes are used. By this arrangement a sheet of water 30 ft. square is exposed on both sides to the fire, thereby securing a very rapid generation of steam, and causing an excellent circulation. The action of this system is demonstrated practically to visitors by models with glass connections in operation at the company's offices.

MESSRS. WILLIS & HUNTER have opened an office at 115 Broadway, for the sale of the Eddy electric motors.

MR. FREMONT WILSON has opened an office at 35 William st., as an electrical contracting engineer.

JUDGE W. H. ARMSTRONG, of the Pacific Electric Storage Co., the licensees of the Electrical Accumulator Co. for the Pacific Coast, was in the city recently.

THE ECONOMIC GAS ENGINE CO. exhibited a new type of gas engine at the American Institute Fair, which has just closed.

THE STANDARD ELECTRICAL WORKS, of Cincinnati, Ohio, have just placed on the market a new gravity drop annunciator possessing several improvements over the old style. The drops are mounted upon iron backs, and the shields are set down close to the magnets, thus securing the full effect of magnetism at the minimum expenditure of current.

NEW INCORPORATIONS.

Lenox Gas and Electric Co., Lenox Mass., W. E. Plunkett, C. E. Merrill and others. Capital, $30,000.

Williamete Falls Electric Co., Portland, Oregon, D. P. Thompson, E. L. Eastman and others. Capital, $1,000,000.

Boonville Electric Light Co., Boonville, N. Y. Capital, $10,000.

Electric Light Co., Augusta, Ga., C. H. Phinizy, C. H. Oetjen and others. Capital, $50,000.

Osage City Electric Light Co., Osage City, Kan., J. B. Marshall and others. Capital, $15,000.

Truckee Electric Light and Power Co., Truckee, Col., W. H. Kruger and others. Capital, $10,000.

Mutual Electric Lighting Co., Jersey City, N. J., S. Marsh Young and others. Capital, $100,000.

Almonte Electric Light Co., Almonte, Ont. Capital, $20,000.

Paris Electric Lighting Co., Paris, Ky., C. S. Varden.

Newport Electric Light Co., Newport, Ky., John B. Taylor and others. Capital, $50,000.

Nebraska Electric Light and Motor Co., Omaha, Neb., D. B. Covell and others. Capital, $500,000.

Phoenix Electric Co., Marshall, Texas, J. H. Gates, John T. Johnson and others. Capital, $25,000.

Lee Electric Light Co., Lee, Mass., Wellington Smith, David Dunn and others. Capital, $10,000.

Ashland Electric Light and Power Co., Ashland, Oregon, H. B. Carter and others. Capital, $15,000.

Chicago Cork Insulating Co., Chicago, Ills., W. S. Driver, A. Ristin and others. Capital, $200,000.

Eastern Electric Construction Co., Portland, Me., G. C. Mosaes and others. Capital, $50,000.

American Fire Alarm Co., Portland, Me., C. F. Blackwell and others Capital, $20,000.

Beaver Electric Light and Power Co., Beaver Falls, Penn., W. H. Hartman and others. Capital, $12,000.

Oakland Electric Light and Motor Co., Oakland, Cal., W. E. Dargie, J. W. Cordes and others.

Cherryfield Electric Light Co., Cherryfield, Me., U. M. Nash and others. Capital, $7,000.

Buena Vista Electric Light Co., Buena Vista, Col., J. Tipton, C. S. Wood and others. Capital, $15,000.

Fort Worth Electric Manufacturing Co., Fort Worth, Texas. Capital, $100,000.

Carthage Electric Light and Power Co., Carthage, Mo., W. B. Myers, T. J. Rittenhouse and others. Capital, $30,000.

Plymouth Electric Light Co., Plymouth, Mass., G. F. Weston, C. E. Morton and others. Capital, $30,000.

Stout Electric and Storage Battery Co., New York, G. H. Stout, R. F. Hill and others. Capital, $200,000.

Notes.

A short time ago the Julien Electric Co. expressed a hope that by their new method of regulations they could so economize the use of the current from their battery as to make three round trips, or thirty-six miles, with one charge on the Fourth and Madison avenues line. They now report that this has been accomplished, and that their large 18-foot cars, carrying unusually heavy loads of passengers, are now making three round trips, from 86th street to the Post-Office and back (or thirty-six miles), without any change of battery. They now change the battery but once a day, thus making a great saving in time. Not content with this performance the Julien company hope to be able to make a fourth trip, or forty-eight miles, on one charge, inasmuch as they find that at the end of the third trip the voltage of the battery is still above two volts per cell. It is claimed that the trip from 86th st. to the Post-Office and back, twelve miles, is made on an expenditure of less than 15 electrical horse-power hours, or thirty-six miles on 45 electrical horse-power hours. Calculating the cost at two cents per horse-power hour the Julien company compute that it costs but thirty cents for energy in a round trip of twelve miles, or two and one-half cents per mile. Assuming seventy-five miles for a car day the cost would be $1.87½. The company give these data from its books at their electrical station, and invite inspection, the records showing the ampere hours and the horse-power hours put into the battery each day, and the cost of the same.

AKRON, O.—The street railway, at Akron, Ohio, equipped with the Sprague system, has five cars in daily service, and one or two additional cars will soon be ready for use. Our report states that the management are much pleased with the operation of the road, and the excellence of the service rendered is a source of pride to the citizens. Recently, while descending a steep grade with a heavily loaded car the hand brake broke. The driver immediately reversed the motors and the car returned to the top of the hill.

BOSTON.—On the Boylston and Beacon street route of the West End Street Railway Co., the Bentley-Knight Co. have completed 1¾ miles of conduit. The extent of the work to be accomplished during the winter will be dependent upon the weather.

LEGAL NOTES.

THE ST. LOUIS TELEPHONE CASE.

SUPREME COURT, STATE OF MISSOURI.

The Ordinance of the City of St. Louis, Regulating Telephone Rates Declared Null and Void.

ABSTRACT OF OPINION BY JUDGE BLACK.

This was a prosecution against the Bell Telephone Co., of Missouri, for a violation of an ordinance which provides that "the annual charge for the use of the telephone in the City of St. Louis shall not exceed $50.00."

The defendant is a corporation organized under article 5, of chapter 21 of the revised statues of this state. They have the power to run and operate lines of telephone, to make reasonable charges for the use of same, to erect their poles along and across public roads and streets, to condemn private property for a right of way, and they are charged with the duty of receiving and transmitting messages with impartiality and good faith.

The defendant contends that the city has no right to fix a maximum rate of charges. The defendant's property, consisting of poles, wires, fixtures, and the like is, of course, private property; but the property is devoted to public use, and since the

defendant has conferred upon it special franchises and privileges, including the right of eminent domain, the corporation is subject to public regulations, and we shall take it for granted that the state has the power to fix and prescribe a maximum rate for telephone service. The important question is whether the City of St. Louis has the power to fix reasonable charges for telephone service. If the city has such power it must be found in a reasonable and fair construction of its charter. Judge Dillon makes this comprehensive statement of the rule as to municipal powers: (1) Those granted in express words. (2) Those necessarily or fairly implied in or incident to the powers expressly granted. (3) Those essential to the declared objects and purposes of the corporation—not simply convenient—but indispensable. The city places some reliance on its general power to regulate the use of streets. This power extends to new uses which spring into existence from time to time, as well as to uses known at the time of the dedication or grant of power to the municipality.

That the company is subject to reasonable regulations by the city as to planting its poles and stringing its wires and the like, is obvious. Conceding all this, we are at a loss to see what this power to regulate the use of the streets has to do with the power to fix telephone rates. * * * But taking these charter provisions together, we think it would be going to an extreme length to say that they confer upon the city the power to fix telephone rates. If it has the power to do this, it may also fix the charges for telegraph services, which are of a public character.

We conclude that the city has no power to pass the ordinance in question by reason of any of the charter powers before considered. This conclusion is manifest when we consider that the charter points out with particularity those cases in which the city may fix rates and charges. Judgment accordingly.

STORAGE BATTERY PATENTS.

The Julien Electric Co. make the following statement:—

"The commissioner of patents at Washington has just rendered a decision supporting Mr. Julien's claim for an inoxidizable alloy as against the claim of the Faure-Sellon-Volckmar combination.

"The Electrical Accumulator Co., of New York, with a view no doubt of testing the validity of Mr. Julien's patent, filed an application in the patent office some time ago for a patent, claiming among other things an alloy containing lead and antimony for a support plate in a secondary battery. The patent office, thereupon put them in interference with the Julien Electric Co. Much expert evidence was offered on both sides. Professor Morton, Mr. Reckenzaun and Mr. Madden testified on behalf of the Electrical Accumulator Co., and Professor Barker, Dr. Van der Weyde and Mr. Salon testified on behalf of the Julien Electric Co. The case was then argued before the commissioner by able counsel on both sides, and the commissioner after due consideration decided in favor of the Julien Electric Co., holding that an alloy of lead and antimony had no novelty, but that an alloy of lead, antimony and mercury, as claimed by Mr. Julien, has specific advantages and novelty.

"It was proved on behalf of the Julien Electric Co., and it has been admitted by the examiner in his opinion, that while an alloy of lead and antimony has serious disadvantages as a support plate by reason of the crystalline structure of the metal making it liable to oxydation and consequent disintegration, yet the presence of mercury removes this defect and makes the alloy homogeneous and practically inoxidizable.

"This decision is not only a great triumph for the Julien Electric Co., but is of widespread interest to the electrical community, who we all know are looking forward to a storage battery constructed on scientific principles."

The following statement is from the Electrical Accumulator Co.:

"A public statement from the Julien company has appeared, which it is made to appear that the application of the Electrical Accumulator Co. for a certain patent has been refused by the United States Patent Office. Such a statement is not true; on the contrary, the commissioner of patents, Washington, has just rendered a decision sustaining the claims of John S. Sellon as the inventor of an inoxidizable alloy support plate, and Mr. Sellon's patent has been passed to issue, and will shortly appear on the patent records duly assigned to the Electrical Accumulator Co. The application of Sellon was founded upon the specification of his English patent No. 3,987, dated September 15th, 1881. This British patent of Sellon's is the first publication to describe the use of a plate of lead and antimony, or an alloy of two metals, either with or without the use and application of an amalgam as a support for the active material in a battery of the Faure type.

"Immediately following the decision of the commissioner above referred to, a second application of Sellon's claiming an alloy of two or more metals and an amalgam, was placed in interference with Julien's patent. It will thus be seen that litigation up to this date in the patent office, has resulted in the substitution of Sellon's second application for the first application which was placed in interference on the allowance or passing of Sellon's first application to issue.

"The issue of this patent in the United States will enable the assignee of Sellon, the Electrical Accumulator Co., to control the manufacture, use and sale of secondary batteries employing lead and antimony in the composition of the support plates, whether mercury to form an amalgam be present or not, and suits will be instituted in the courts for the recovery of damages at once."

THE RELATIONS OF FOREIGN TO U. S. PATENTS.

MR. H. PALM (Michalecki & Co.), civil engineer and patent agent, Vienna, has kindly sent us the following communication, which will be found of much interest to all who are interested in inventions patented both in the United States and abroad:—

Dear Sir—In an actually pending patent suit, a court of justice of first instance in the United States of America has declared Austro-Hungarian patents for which, on filing the application, the fee has been paid for one year only, to be one year patents, in consequence whereof a United States patent, granted for the same invention, after the grant of the Austro-Hungarian patent, would likewise have a duration of one year only. In consideration of this fact, it cannot fail to be of interest, to learn the wording of an official declaration given by the Austrian Imperial Royal Ministry of Commerce in reply to a request presented by the Austrian attorney of the patent proprietor against which the judgment of the United States court had been pronounced. This official declaration runs as follows:

Imp. Roy. Ministry of Commerce.
No. 21,893.

OFFICIAL CONFIRMATION.

By these presents, the Imp. Roy. Ministry of Commerce in Vienna confirms:—

1st. That, according to § 25 of the Imperial Charter of the 15th August, 1852, No. 184 of the Bulletins of Laws of the Empire, the term of the longest duration of any patent granted, without exception, is limited to 15 years, this duration running on uninterruptedly, provided that the patentee complies with the conditions mentioned under 2; — that this primitive term of 15 years belongs, without exception, to every patent granted under the provisions of the Imperial Charter of the 15th August, 1882, No. 184 of the Bulletins of Laws of the Empire;

2d. That, according to § 11 of the Patent Law, the patentee is not bound to pay at once, in advance, the fee for all 15 years, but that he is permitted to pay the fee by annuities;

3d. That, on the patent documents of an Austro-Hungarian patent granted under the provisions of the law referred to hereinbefore, the mention of one or more years, beside the authentication of the grant of the patent, exclusively purports to confirm, that the patent fee annuities have been paid in advance for one or more years, and that hereby the term of the granted patent is in no way affected, as this term, according to the above statement, is limited to 15 years by the law.

4th. That, when the patent fee is paid in annuities, viz., from year to year, the several payments do not bring about an extension of the duration of the patent, as this duration is fixed, from the origin, according to the law, but these payments only prevent the cease of the patent before the expiration of the term of 15 years, for which it has originally been granted, on the ground of the patentee failing to pay the prescribed fee;

5th. That the Imp. Roy. Ministry of Commerce in order to prevent erroneous interpretations relatively to the term of Austro-Hungarian patents by foreign authorities, has felt induced as early as in July, 1884, to replace the printed blanks of patent documents, then in use, by other blanks, which leave no doubt as to the term of an Austro-Hungarian patent.

THE IMP. ROY. MINISTRY OF COMMERCE.

Vienna, the 18th July, 1887.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From November 20 to December 18, 1888 (inclusive).

Alarms and Signals:—*Electric Alarm System*, W. F. Rossbach, 393,078, November 20. *Electric Light Burglar-Alarm Indicator*, R. Packer and I. E. Cochran, Jr., 393,657. *Electric Bell*, A. Lungen, 393,710, November 27. *Electric Bell*, J. F. McLaughlin, 393,996. *Electric Annunciator-Target*, F. J. Patten and T. A. Bingham, 394,081, December 4. *Electric Alarm and Water Gauges*, J. H. Johns, 394,491, December 11. *Annunciator*, W. C. Clark 394,555. *Electric Signaling Apparatus*, G. F. Milliken, 394,784. *Magneto-Generator for Fire-Alarm Circuits*, W. L. Denio, 394,839. *Electric Push Button*, A. J. Hoyt, 394,925, December 18.

Clocks:—*Synchronizing Mechanism for Clocks*, E. Kronenberg, 393,159, November 20. *Electric Striking Attachment for Clocks*, J. H. Gerry, 393,637. *Pendulum-Regulator for Clocks*, same, 393,638, November 27.

Conductors, Insulators, Supports and Systems :—*Conduit for Electric Conductors*, J. Kames, 393,018. *Insulating Composition*, A. Poitevent, 393,-099. *Underground Conduit for Electric Conductors*, C. J. Van Depoele, 393,-276. *Arched Suspender for Overhead Electric Conductors*, same, 393,317. *Electrical Conduit*, J. Whelan, 393,346, November 20. *Art of Laying Underground Conduits*, W. Lake, 393,477. *Non-Conducting Composition* S. Heimann, 393,644, November 27. *System of Suspending Electric Conductors*, C. J. Van Depoele, 394,039. *Submarine and Subterranean Electric Cable*, E. Flotron and F. B. A. R. De la Bastie, 393,823, December 4. *Electric Underground Conduit*, D. O. Paige, 394,207. *Wire Holder for Insulators* E. L. Lloyd, 394,380, December 11.

Distribution :—*Transformation and Distribution of Electrical Energy*, W. J. McElroy and T. J. McTighe, 393,073. *Distribution of Electricity by Secondary Batteries*, H. Edmunds, 393,147, November 20. *Distribution of Electricity by Secondary Batteries*, W. W. Griscom, 393,470, November 27. *Electric Distribution by Secondary Batteries*, Z. Latshaw, 394,541, December 11. *Distribution of Electricity by Secondary Batteries*, T. P. Conant, 394,642. *Conveying Electric Energy*, S. Z. De Ferranti, 394,837 and 394,838, December 18.

Dynamos and Motors :—*Electric Motor and Dynamo*, A. L. Riker, 393,266. *Switch for Electric Motors*, G. H. Condict, 393,323, November 20. *Electric Motor*, F. J. Keller and J. W. Carnes, 393,373. *Oiler for Commutators*, T. E. Craig, 393,422. *Regulatiou of Alternate-Current Generators*, G. Pfannkuche, 393,448. *Dynamo-Electric Machine*, W. W. Griscom, 393,469. *Regulator or Cut-off for Generators*, D. W. Smith, 393,590. *Dynamo-Electric Machine and Electric Motor*, W. P. Freeman, 393,636, November 27. *Electric Motor*, C. J. Van Depoele, 394,035. *Duplex Electromotor*, same, 394,036. *Electric Motor and Dynamo-Electric Machine*, O. Lugo, 394,075. *Commutator*, C. L. Buckingham, 394,095. *Dynamo-Electric Machinery*, W. F. Collins, 393,742. *Armature for Dynamo-Electric Machines*, L. Daft, 393,745. *Dynamo-Electric Machinery*, S. E. Nutting, 393,849, December 4. *Safety Device for Electric Motors*, C. J. Van Depoele, 394,417. *Safety Device and Signal for Electric Motors and Generators*, same, 394,525, December 11 *Dynamo-Electric Machinery*, C. S. Bradley, 394,818 and 394,819. *Dynamo-Electric Machine*, G. W. Riethmann, 394,883. *Armature Core for Dynamo-Electric Machinery*, W. S. Belding, 394,905, December 18.

Galvanic Batteries :—*Galvanic Battery*, F. H. Root, 393,123. *Gravity Battery*, L. C. Bartley, 393,203, November 20. *Porous Cup for Galvanic Batteries*, H. J. Brewer, 393,353. *Galvanic Battery*, H. L. Roosevelt, 393,395 ; J. L. Gethins, 393,639, November 27 ; P. C. Burns, 393,814, December 4. *Separating-Partition for Galvanic Batteries*, I. L. Roberts, 394,613. *Separating-Diaphragm for Galvanic Batteries*, same, 394,614. *Treating Diaphragms and Cups for Use in Electric Batteries*, same, 394,615. *Diaphragm for Galvanic Batteries*, same, 394,616 and 394,617. *Separating-Partition for Galvanic Batteries*, H. L. Brevoort and I. L. Roberts, 394,638. *Galvanic Battery*, R. D. Wright, 394,670. *Carbon Electrode for Electric Batteries*, J. Beattie, Jr., 394,810, December 18.

Ignition :—*Electric Gas Lighter*, C. H. Haskins, 393,304, November 20. *Automatic Gas Lighting and Extinguishing Apparatus*, N. H. Shaw, 393,525, November 27. *Electrical Fuse*, J. Macbeth, 394,192, December 11.

Lamps and Appurtenances :—*Electric Light Pole*, E. Thomson, 393,040, November 20. *Filament for Incandescent Lamps*, G. S. Ram, 393,391. *Arc Light*, D. B. Turner, 393,405. *Electric Arc Lamp*, G. Pfannkuche, 393,447. *Incandescing Electric Lamp*, E. H. Johnson, 393,473. *Electric Light Regulator*, L. Paget, 393,574. *Globe for Electric Lamps*, S. Heimann, 393,704. *Incandescent Electric Lamp Socket*, W. F. Wollin and E. H. Werline, 393,733, November 27. *System of Electric Lighting*, W. W. Griscom, 393,756. *Train-Lighting by Secondary Batteries*, same, 393,757, December 4. *Lamp Hanger*, D Chisholm, 394,153. *Cut-Out for Electric Lamps*, C. Heisler, 394,180, December 11. *Support for Incandescent Electric Lights*, A. Dawes, 394,680. *Electric Arc Lamp*, R. Schefbauer, 394,791, December 18.

Measurement :—*Instrument for Measuring Electric Currents*, A. G. Waterhouse, 393,063. *Electric Meter*, F. C. Wagner, 393,132 ; W. F. Stocker, 393,315, November 20 ; A. Reckenzaun, and J. A. Pentz, 394,880 ; A. Reckenzaun, 394,-881, December 18.

Miscellaneous :—*Electrical Apparatus for Preventing Corrosion of Steam-Boilers*, A. J. Marduand, 393,072. *Apparatus for Removing Frictional Electricity from Machinery*, W. Schulte, 393,125. *Mechanism for Changing Electric Circuits, &c.*, H. Edmunds, 393,146. *Apparatus for Electro-Plating* L. McMurray. 393,170. *Electrical Revolving Brush*, R. Thayer, 393,192. *Electro-Magnetic Door-Opener*, E. A. Wildt, 393,282. *Electro-Magnet*, F. A. Lane, 393,337, November 20. *Apparatus for Removing Metallic Particles from Paper Pulp*, C. H. Atkins, 393,348. *Switch or Circuit-Changer*, W. W. Griscom, 393,365. *Controller for Electric Circuits*, W. J. Paine, 393,389. *Natural Gas Protective Extinguisher*, C. E. Scribner, 393,396. *Device for Exhibiting Magnetic and Non-Magnetic Watch Movements*, A. C. Smith, 393,402. *Process of Making Phonogram-Blanks*, T. A. Edison, 393,462. *Machine for Making Phonogram-Blanks*, same, 393,463 and 393,464. *Method of Preparing Phonograph Recording-Surfaces*, same, 393,465. *Phonograph Recorder*, same, 393,466. *Electric Depositing Cell*, E. L. Smith, Admstr., 393,526. *Electric Letter-Box*, C. F. Harms, 393,558. *Production of Zinc Chloride, &c.*, L. Paget, 393,578. *Electric Fluid-Pressure Engine*, G. Westinghouse, Jr., 393,596. *Coin-Operated Induction Coil*, C. Durieux, 393,624 and 393,625. *Phonograph*, E. T. Gilliland, 393,640. *Electric Door-Opener*, A. Lungen, 393,711, November 27. *Workman's Electric Time-Recorder*, W. K. Bassford and E. B. Maynard, 394,040. *Thermopile*, H. Woodward, 394,090. *Phonograph-Recorder*, T. A. Edison, 394,105. *Phonograph-Reproducer*, same, 394,106. *Voltaic Plaster*, W. C. Collins, 393,741. *Electrical Water Elevator for Buildings*, A. E. Hall, 393,826. *Semaphore-Signal*, F. Stitzel and C. Weinedel, 393,865. *Method of Recording and Reproducing Sounds*, T. A. Edison, 393,966 and 393,967. *Phonograph-Recorder*, same, 393,968, December 4. *Electric Dispatch-Tube*, W. Dulles, Jr., 394,161. *Electric Contact Maker*, J. S. Farmer, 394,164. *Electro-Magnetic Air-Compressing Rock Drill*, R. G. G. Moldenke, 394,203. *Electric Valve-Operating Device*, F. M. Sparrow, 394,220. *Acid-Proof Receptacle and Lining Therefor*, E. R. Rand, 394,296. *Thermo-Electric Valve-Controller*, F. M. Sparrow, 394,307. *Electro-Mechanical Movement*, B. Cadwallader, 394,332. *Thermotic Circuit-Closer*, W. H. Soley, 394,413. *Electro-Magnetic Switch*, W. W. Griscom, 394,485, December 11. *Temperature Regulator*, L. F. Easton, 394,563. *Switch or Circuit-Changer*, W. W. Griscom, 394,568. *Indicator for Electric Circuits*, O. B. Shallenberger, 394,728. *Collector*, J. Tregoning, 394,797. *Electro-Therapeutic Tool-Holder*, A. H. Bacon, 394,807. *Portable Electric Welding Apparatus*, E. Thomson, 394,892. *Electric Circuit*, J. B. Wood, 394,946, December 18.

Railways and Appliances :—*Metallic Connector for Electric Railways*, J. Kames, 393,012. *Electric Railway*, S. D. Field, 393,224. *Station Indicator*, J. I. Irving, 393,237. *Closed Conduit for Electric Railway Conductors*, C. J. Van Depoele, 393,275. *Turn-Out and Crossing for Underground Conduits*, same, 393,277. *Switch for Overhead Conductors*, same, 393,278. *Electric Railway System*, D. G. Weems, 393,280, November 20. *Train Signal*, A. C. Griggs, 393,431. *Apparatus for Propelling Cars*, L. Paget, 393,572. *Conduit for Electric Railways*, M. Dallas, 393,622, November 27. *Motor for Street Cars*, W. S. Salisbury, 394,015. *Constant Upward-Pressure Contact for Overhead Conductors*, C. J. Van Depoele, 394,037. *Duplex Upward-Pressure Contact*, same, 394,038. *Apparatus for Removing Scale from Electric Conductors*, L. Daft, 394,062. *Sectional Double-Line Electric Railway*, S. H. Short, 394,139. *Trolley*, F. E. Fisher, 393,749, December 4. *Electric Tramway*, M. H. Smith, 394,621. *Electric Brake System*, W. P. Widdifield and A. H. Bowman, 394,627. *Conduit for Electric or Cable Railways*, T. W. Harris, 394,648. *Driving Gear for Electro-Magnetically Propelled Vehicles*, W. L. Stevens, 394,734. *Electro-Magnetically Propelled Vehicle*, same, 394,735. *Electric Locomotive*, S. H. Short, 394,887, December 18.

Storage Batteries :—*Time-Switch for Secondary Batteries*, W. F. Stocker, 393,183, November 20. *Storage Battery*, L. Paget, 393,573. *Secondary Battery*, same, 393,575, 393,576 and 393,577, November 27. *Indicator for Secondary Batteries*, S. C. C. Currie, 393,744 and 394,100. *Mode of Making Secondary Battery Plates*, W. W. Griscom, 393,755. *Method of Producing Electrodes for Secondary Batteries*, H. Woodward, 393,954. *Electrode for Secondary Batteries*, H. Woodward, 393,955, December 4. *Secondary Battery*, L. Duncan, 394,471. *Method of Making Secondary-Battery Plates*, same, 394,472 and 394,473. *Secondary-Battery*, same, 394,474, December 11. *Connector for Secondary Batteries*, H. H. Wiegand, 394,897, December 18.

Telegraphs :—*Printing Telegraph*, G. V. Sheffield, 394,302, December 11. *Telegraphy*, P. F. Jamieson, 394,697, December 18.

Telephones, Systems and Apparatus :—*Electro-Magnetic Shunt for Telephone-Receivers*, T. D. Lockwood, 393,165. *Telephone Apparatus*, J. B. Ker and J. Crawford, 393,243, November 20. *Multiple Switch-Board*, M. G. Kellogg, 393,508 and 393,509. *Telephone Exchange*, W. B. Vansize, 393,529. *Telephone System*, C. W Brown, 393,612, November 27. *Telephone Exchange-Switch Fastener*, W. M. Goodridge, 393,824, December 4. *Signaling Dynamo-Electric Machine*, E. Gray, 394,172. *Ringing-Off Device for Telephones*, A. Griffith and H. A. Burbank, 394,173. *Bridge for Cutting in New Loops in Telephone Systems*, G. S. Maxwell, 394,195. *Telephone Central-Station Apparatus*, T. N. Vail and J. A. Seely, 394,230, December 11. *Telephone System*, J. F. Casey, 394,832. *Telephone Exchange System*, same, 394,833 ; G. F. Durant and H. L. Bailey, 394,914, December 18.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in January 1889.

Reported for the ELECTRICAL ENGINEER, *by* F. B. Brock, *Patent Attorney*, 639 *F street, Washington, D. C.*

Gas Lighting, Electric,	W. Klinkerfues,	122,389, Jan. 2, 1872.	
Indicators, Electric,	S. Chester,	122,437	"

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VIII. NEW YORK, FEBRUARY, 1889. No. 86.

THE EFFECT OF THE SUPREME COURT DECISION.

THE decision rendered on January 21st, by the Supreme Court of the United States in the case of the Bate Refrigerator Co. against Hammond, involving the determination of the question as to the effect of the existence of a foreign patent upon the term of a patent subsequently issued in the United States to the same inventor, having excited an especial degree of interest in electrical circles, we have reprinted it in full in another part of this issue.

The case arose upon the construction of Section 4887 of the Revised Statutes, the language of which is as follows :—

Sec. 4887. No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than seventeen years.

The difficulty in construing the statute arises from the circumstance that certain foreign countries grant patents for a short term of from one to six years, which may be extended upon the payment of certain fees and after compliance with certain statutory provisions.

The facts in the present case were these :—A patent was granted to the inventor in the United States on November 20th, 1877. He had, however, obtained a patent in Canada for the same invention on January 9th, 1877, although the application for the Canadian patent had not been made until after the application in this country. The Canadian patent was originally granted for a term of five years and was afterwards extended to the full term of fifteen years. The Circuit Court of Massachusetts held that the meaning of the section of the Revised Statutes above quoted is, that any United States patent granted after the issue of a foreign patent, expires with the foreign patent. This and other Circuit courts have held in other cases as well as in the Bate case that the original Canadian term of five years was controlling, and that the United States patent expired therewith whether that term had been extended or not.

The Bate case having been appealed and placed upon the calendar of the Supreme Court, the Edison Electric Light Co., a number of whose most important patents were similarly circumstanced, arranged with the Bate company to lend them the assistance of counsel in arguing the case before the Supreme Court. In due course the Bate case could hardly have been reached for two or three years to come, but through the persistent efforts of the counsel of the Edison company the Supreme Court permitted the substitution of the case for another one near the head of the docket and about to be heard. The Bate case was accordingly argued on January 2, 3, and 4, by William M. Evarts and Clarence Seward for the appellants and Chauncey Smith, B. F. Thurston and G. H. Lothrop for the appellees. A brief was also filed in behalf of the United States Electric Lighting Co., the Westinghouse Electric Co., the Consolidated Electric Light Co., the Thomson-Houston Electric Co. and the Fort Wayne Jenney Electric Light Co., the business of all these companies being supposed to be affected in some manner by the result of the decision.

The principal points contended for by the counsel for the appellees, were, first : that the statute applies to patents for inventions patented abroad before the *grant* of the patent here, and not merely to patents for inventions patented abroad before the date of the *application* here ; and second : that it limits the term of the domestic patent by the current term of the foreign patent existing at the time of the domestic grant, without regard to any subsequent extension or curtailment dependent upon uncertain events.

The first of these questions is really the important one, and it is on some accounts to be regretted that the Court did not find it necessary to decide it explicitly but left it to stand as heretofore interpreted by the Circuit courts. With respect to the second point, the established principle that the American patent shall expire with a prior foreign patent is reaffirmed ; but, in contravention of the opinion of the lower court, the Supreme Court holds that the Canadian patent, by reason of having been extended, has never actually expired.

The effect of the decision is, in short, that the term of the domestic patent is determined by the duration of the uninterrupted term of the prior foreign patent. The exact language used is, that " it is to be in force as long as the foreign patent is in force." The language of the decision clearly implies that the extended or prolonged term of the foreign patent must be continuous with the original grant, and hence the occurrence of any interregnum would be fatal to the domestic patent. Incidentally, it is affirmed that the limitation need not be expressed on the face of the

domestic patent, although the contrary has been held in at least one instance in the lower court.

The real importance of this decision appears to us to have been very much overrated by the newspapers, although there is no doubt that the position of some of the leading electric lighting companies, notably the Edison and the United States companies, has been materially strengthened by it. Indirectly, we think it will have a beneficial effect upon all the stronger electric companies, as increasing the actual value of all property and industries founded upon patents.

PATENT OFFICE REFORM.

The New York *World* has during the past few weeks published a number of articles reflecting severely not only upon the general plan of organization of the United States Patent Office but upon the capacity and integrity of the examining force. Not only are general charges of inefficiency and corruption freely made, but in some instances the allegations are aimed at specific persons. A great number of inventors, attorneys and patent solicitors of more or less prominence, have also been "interviewed," and the remarks attributed to them are, in some cases at least, rather spicy reading. On the whole, however, their testimony is rather in favor of the employés of the Patent Office than otherwise. It is especially noticeable that those patent solicitors of the highest standing in their profession, who handle cases involving the most important and valuable inventions, were the ones who had the least fault to find with the examiners as a body, while others, especially one or two whose incapacity may fairly said to be abnormal, improved the occasion to criticise and denounce the office, the system, and every person connected therewith, in the most unmeasured terms.

That mistakes, delays, and obstructions of the most exasperating nature, too frequently occur during the passage of applications through the Patent Office, no one is more ready to admit than many of the examiners themselves, but they nevertheless contend, and with much justice, that in most cases the fault is inherent in the organization of the office, and does not lie primarily with themselves, in short, that the remedy rests with Congress, and not with the Commissioner of Patents.

The writer has become quite familiar, by many years of experience, with the workings of the Patent Office in one of its most difficult classes, that of electricity, and has prosecuted a large number of applications, many of them involving very large commercial interests, usually to a successful issue. Of course, this has in many instances not been done without friction, and even in the face of positive and unnecessary obstruction. We have known a device, as ingenious as it was simple, and as novel as it was useful, to be rejected no less than 13 times, only to be finally allowed and patented exactly as it was originally presented. But, nevertheless, we must in justice to the examining corps place upon record the fact that with rare exceptions, we have found them to be courteous, intelligent, and, above all, honest. We have never had reasonable ground for suspicion that adverse influences of an improper character were enlisted against us. On the other hand, it gives us pleasure to acknowledge, some of the most valuable claims we have ever taken from the office have been due to the criticisms and suggestions of well-informed and experienced examiners. Even the "obstructionists" found here and there among the incumbents, who are so heartily anathematized by the unfortunate solicitor who happens to collide with one of them, like most objectionable things, are not wholly without their uses. Many a specification or claim has been wonderfully improved by the careful scrutiny, the frequent rewriting, or the novel method of presentation necessitated by the perverse, stupid and ignorant objections of some callow youth, inflated almost to bursting with a superabundance of that extraordinary form of energy, which for want of a better name, we term "officialism." In short, we have rather felt that we had cause to be thankful that so efficient and capable a body of men as the examiners generally could be found, and retained for a reasonable time in the service upon such inadequate compensation. The electrical class has been peculiarly fortunate in this respect, and we can only hope that we will fare no worse hereafter than we have done heretofore.

For our own part we agree substantially with the opinion attributed by the *World* to Mr. E. S. Renwick, and concurred in by many others whose views are entitled to great weight, which, in effect, is that the present system of examination, while it has served fairly well in the past, must inevitably break down from its own weight at no distant day, in consequence of the enormous and rapidly increasing aggregation of inventions in all parts of the world, all of which, in each class, must in theory at least, be compared with every new invention which is presented to the office for examination.

It is probable that the best attainable plan will be found to be one in which the Commissioner has no power to refuse a patent for an application when presented in proper form, so as to contain a "full, clear and exact description" of the invention, and a definite statement of what is claimed to be new. Examination should be made, as fully and carefully as possible, and a reference to all alleged anticipating publications, public uses, etc., discovered in this way, should be printed and annexed to the patent, thus enabling every person to do what careful persons always do now before dealing with a patent, that is, examine the references cited by the examiner and judge for himself of their pertinency and importance.

Some plan ought also to be devised which will do away with the whole system of trying interference cases in the Patent Office, and relegate them immediately to the existing Federal courts or to a separate patent court such as the Court of Patent Appeals for the establishment of which the congressional bill introduced last year made adequate provision.

It is to be hoped that the agitation commenced by the *World* will result in awakening Congress to some sense of its duties towards the Patent Office, and towards the inventors of America, a matter quite as important to the country as the question of the tariff.

.... In 1875, it was thought wonderful to transmit messages to Ireland, at 80 words a minute. When I was recently in Belfast, I timed messages coming at the rate of 461 words a minute.—*W. H. Preece.*

THE EDISON CONSOLIDATION.

The incorporation, under the laws of New Jersey, of the Edison General Electric Co., with a capital stock of $12,000,000, marks the consummation of the negotiations which were the basis of the rumors and newspaper gossip current a few weeks ago.

The new company takes over the plant and business of the several Edison manufacturing companies, namely : The Edison Machine Works, Schenectady, N. Y., the Edison Lamp Co., East Newark, N. J., and Bergmann & Co., New York. It also acquires the property and business of the parent organization, The Edison Electric Light Co., and supplants the Edison United Manufacturing Co. in the trade in isolated plants. A large amount of new capital has been put into the new company, furnished, it is understood, by a syndicate through Mr. Henry Villard, whose part in the transaction attracted so much notice by the daily press a month ago.

The Edison General Electric Co. will thus own and manage the entire Edison interests in electrical distribution and lighting. It is further announced that branch offices will be established in all the leading cities, and that the erection and operation of local central station lighting plants will be a prominent feature in the business of the new company.

The large accession of capital and the more compact organization attending these changes, together with the considerably improved position of some of the Edison patents resulting from the recent decision of the United States Supreme Court in the Bate refrigerator case, add material strength to the position of the Edison interests in the competition with their energetic rivals in the business of electric lighting.

ELECTRICAL EXECUTIONS.

On the occasion of his address to the Electric Club of New York, December 20th, Professor Brackett expressed the opinion that no criminal would ever be executed by the agency of electricity in this state notwithstanding the legislation ordaining that method of execution upon the perpetrators of capital crimes committed after the first of January, 1889. We are inclined to agree with Professor Brackett in his opinion for several reasons. It is much easier to get laws made than to put them in operation, and the proposed change has apparently no popular support. The legislation ordaining it seems ill-considered, being based upon a very inadequate report by the commission appointed "to investigate and report the most humane and practical method of carrying into effect the sentence of death in capital cases." In the matter of bulk the report is more than adequate, but it fails to show that execution by electricity is either the most humane or the most practical method to be found. It is not shown to be more humane than the administration of a sudden poison, gaseous or liquid, and it is certainly much less convenient. How far electricity is from being the "most practical" method is well illustrated by the toilsome months occupied by the Medico-Legal Society in their efforts to discover the best mode of applying it. Although a special committee of that society has investigated the subject with the assistance of such electricians as it could interest in the matter, and has made two reports, it is not quite sure yet as to the best method, beyond recommending a minimum capacity of dynamo and an alternating current. Notwithstanding the excellent motives of the humane gentlemen who initiated and promoted the legislation of last winter we do not believe their plan will succeed.

It is sensational and mysterious to the general public. It is too experimental in character to commend itself to the calm judgment of penologists and legislators. The act ordaining it would better be repealed than put in operation.

RIVALS UNITED.

The arrangement between the Westinghouse Electric Co. and the United States Electric Lighting Co., announced a few days since, proves to be to all intents and purposes a consolidation of the two interests under the control and management of the first-named organization. The United States is one of the oldest and best known electric light companies in the country. It has always done a large business, but has been seriously handicapped by the unfortunate necessity incident to many pioneer enterprises of expending large sums of money not only in experimenting and in litigation, but in the reconstruction of its early plants in order to keep pace with the rapid progress and development of invention. It has, moreover, borne a large share of the costly burden of educating a skeptical public to appreciate the manifold advantages of electric illumination, and of overcoming the endless legal and other obstructions due to ignorance and prejudice, labors which, while necessary and unavoidable, are by no means pecuniarily profitable. The value of the service thus rendered by the United States Company to electric interests has been but scantily appreciated, even by those who are profiting most largely by it at the present day. The union of its fortunes with those of a strong and energetic concern, like the Westinghouse company, will enable the United States stockholders to reap something like a fair share of the results of their own labors and sacrifices. This consolidation is but another proof of the inevitable tendency of events, which we have frequently pointed out, towards an ultimate union of the important electric light companies under a common executive management. Practically the present consolidation leaves but four strong organizations in the field, if we except the Western Electric Co., which, of late, manifests indications of an intention to increase the scope of its great general electric business, by taking a larger part than heretofore in the field of electric light and power at some future and not very distant day. The electric lighting business, on the whole, appears to be rapidly getting down to a business basis.

The press despatches sent from Washington announcing the decision of the Supreme Court in the Bate patent case were, if possible, even more contradictory and ambiguous than usual in their statements of the points really covered by the decision ; nevertheless the reporter of a leading New York evening paper promptly started out to interview various persons of more or less prominence to obtain their views on the matter. Among others the scribe called upon

the secretary of the Edison Electric Light Co., who is said to have exclaimed with youthful enthusiasm :—

"The decision in the Bate case covers exactly the same points upon which nearly one hundred of our most important lawsuits depend. This decision simply means that the only defense set up by our rivals is now broken down. It practically assures us a monopoly of the incandescent lighting system. * * * * Our competitors are virtually all knocked out, and are worse off even than if they had never begun business." But, unfortunately, when the full text of the decision came to hand it turned out to be a horse of another color altogether. The point vital to the Edison company, and the one which had been strenuously urged by them from the beginning, was that the statute of limitation did not apply to patents for which the *applications* in this country had been made prior to the date of the foreign patents, the contrary having been held by the Circuit courts in at least four important cases since 1882. The Supreme Court, it now appears, expressly declines to reverse the Circuit court decisions upon this point, and hence the law remains unchanged on that point. If the Edison company had been fortunate enough to secure a favorable decision in this particular, it would certainly have gone a long way towards giving them the monopoly hoped for ; but, as it is, the result though of unquestionable benefit to it, is beneficial also to some of its most aggressive rivals, while so far from overthrowing the only defense set up by competitors, it merely puts the company in the position to institute suits which must be tried on their merits in the usual tedious and expensive manner. It was largely with a view of avoiding lengthy and costly litigation that the companies opposed to the Edison interests sought to make a short cut by joining in the appeal of the Bate case. It is such a very long way out of the woods yet that much of the crowing heard during the past week seems scarcely justified by the facts as they exist.

It is announced that the authorities of Columbia College have undertaken the establishment of a course in Electricity and Electrical Engineering. This should be welcome intelligence to young men seeking such training and to the managers of the large industrial companies founded upon applications of electricity. Several high class technical schools have successfully established such courses, but more are needed. It still remains true that the great electrical companies find it difficult to secure a sufficient number of men equipped with the theoretical knowledge requisite to direct and supervise the technical part of their work. The Columbia School of Mines has demonstrated its capacity to train mining and civil engineers and, it may safely be assumed, will be no less successful in the projected new department.

The meetings of the Institute of Electrical Engineers during the present season are proving to be of much interest and importance. The paper of Mr. E. G. Acheson, January 8, on "Lightning Arresters and the Photographic Study of Self-Induction" which we print in full in this issue, was timely and very suggestive in view of much recent discussion of related topics by prominent investigators. At the meeting of February 12, Lieut. F. Jarvis Patten will read a comprehensive paper on Multiplex Telegraphy, including an account of his own recent work in that field. In March, Professor E. L. Nichols, of Cornell University, is expected at the Institute meeting with a paper on "The Efficiency of Methods of Artificial Illumination."

The half-yearly convention of the National Electric Light Association, to be held at Chicago, February 19, 20 and 21, not only promises to be unusually well attended, but in the matter of exhibits will no doubt far outstrip any previous convention. With characteristic enterprise the western members of the executive committee, headed by Mr. B. E. Sunny, have exerted themselves to make the exhibition a success in the variety and extent of the apparatus and supplies to be shown, as well as in the accommodations for displays and their convenient inspection by members of the association and visitors.

We have much pleasure in re-printing Professor Brackett's striking address of December 20th, before the Electric Club of New York, notwithstanding the lapse of time since its delivery. The address touches several important and timely topics in a peculiarly suggestive and felicitous manner. Our reprint has the advantage of the correction by Professor Brackett of several errors found in its earlier publication elsewhere.

Our congratulations are extended to Mr. T. Commerford Martin and Mr. Clarence E. Stump, upon their acquisition of a proprietary interest in the W. J. Johnston Co., Limited, which corporation succeeds Mr. W. J. Johnston, in the publication of the *Electrical World*, from January 1, 1889.

The next Semi annual Convention of the Association of Edison Illuminating Companies will be held at Kansas City, Mo., on Tuesday, February 12th. Accommodations have been arranged for the members of the Association at the Coates House, Kansas City.

OBSERVATIONS.

The daily press has unearthed another prior inventor of the telephone. In a special despatch to the Associated Press—dated Des Moines, Ia., one P. N. Pease is reported to claim the original invention of the telephone. The despatch goes on to say :—"He produces evidence to substantiate his claim which will be investigated by the Patent Office. Pease began experimenting in 1855, his efforts were crowned with success in 1857, and in that year he filed a caveat in the Patent Office, under the name of the Electric Musical Telephone. Later he perfected a telephone, and in 1872 his invention was described in a book entitled, "Wonders of Electricity." It will be seen that there is nothing mean about Pease. It is not surprising that he originally invented the telephone. Many persons have done that. But to have discovered that the description of the suggestion of Bourseul and the work of Reis, found in the "Wonders of Electricity," really means Pease, shows genius of an abnormally high order. The only moneyed men, we fear, who will take stock in Pease will be those who don't know beans.

However, there is no reason why Mr. Pease should'nt step into line with the rest. Let us have Pease.

There is lots of fun in reading over books which incidentally give what they suppose to be information concerning electrical subjects. Looking over an old bookstand the other day, the observer picked up a book entitled "Sunshine and Shadow in New York." Turning over the leaves revealed the date of publication, 1868, and disclosed a description of the New York main telegraph office at 145 Broadway. The author wrestles with the switch-board as follows :—

"A curious instrument is used in the American company's office, which is called a telegraph switch, operating somewhat like a switch on a railroad track. With it, a message can be switched off at any moment, at any point, to let an incoming despatch have the track.

ARTICLES.

A SKETCH OF THE HISTORY, DEVELOPMENT AND PRACTICAL APPLICATION OF THE ELECTRICAL CONDENSER.

BY WM. MAVER, JR.

(Continued from page 21.)

PART II.

A SOMEWHAT generally adopted method of arranging the plates and dielectric of the modern condenser is that devised by Varley, in which one corner of the plates of tin-foil, A and B, and two corners of the dielectric C, are clipped, as in figure 6. Each series of plates of tin-foil is placed with the cut corners together; the cut corners of each

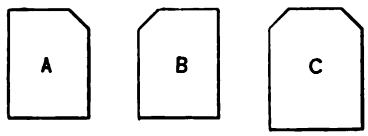

Fig. 6.

alternate series of plates being placed on opposite sides, with the dielectric between and extending beyond the edges except at the clipped corners. This arrangement permits the plates of each series to be readily connected together without danger of short-circuiting with the alternate series. Another method is frequently employed in which all the sheets of foil are placed evenly throughout, and a small strip of tin-foil inserted between each sheet of tin-foil and the dielectric, the strips of the alternate plates being then connected together.

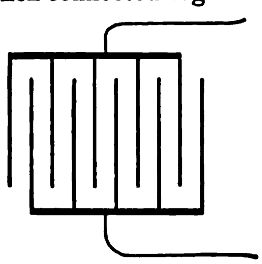

Fig. 7.

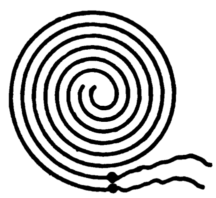

Fig. 8.

There are two general forms or shapes into which the sheets of foil and dielectric are arranged, namely, the flat and cylindrical—figures 7 and 8. These forms are, however, varied as to length, width and thickness, to any desired extent.

One of the latest improvements in the arrangement of the condenser is found in the Marshall multiple-series condenser, in which the different sections can conveniently be placed in series or multiple or in a combination of both or entirely separate one from the other. A diagram of the connections of this arrangement, which represents such a condenser having ten sections, is shown in figure 9. The manner of connecting the plates to the brass strips 1, 2, 3, etc., is shown in three instances in the figure. D E are the usual metallic connecting strips. In the figure three sections of plates are shown connected in multiple arc, by the insertion of plugs. Sections 8 and 9 are joined in series by means of a piece of wire and binding posts similar to that shown separately in the figure. Section 7 is shown as discharged or short-circuited by the insertion of a plug between the two strips, and section 5 is shown as being used independently of the other sections. Assuming the capacity of each section to be .1 M. F., this condenser would have a range of from 1. M. F. to .01 M. F., besides being capable of providing, if necessary, ten separate condensers of .1 M. F. each.

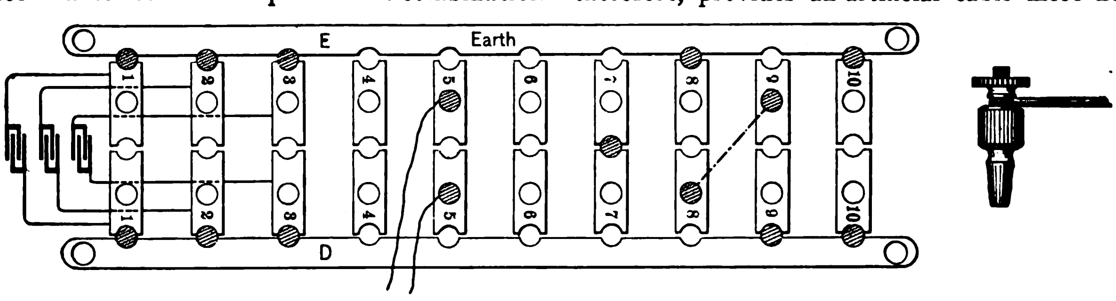

Fig. 9.

The condenser as used in frictional electric gas lighting machines is somewhat different in construction from the ordinary modern condenser. It is composed of a few sheets of tin-foil separated by thin sheets of hard rubber, the outside foil being covered also with hard rubber, the whole not being over .25 inch thick. A condenser of this form about one foot square will accumulate from the plate-electric machine of the apparatus a charge sufficient to produce a spark two inches long.

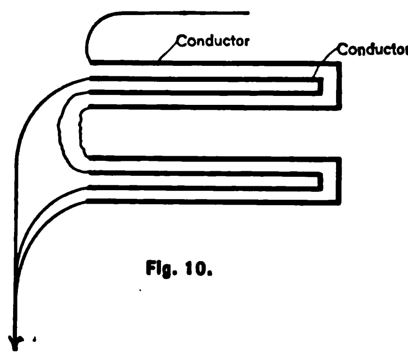

Fig. 10.

Another form of condenser is that known as the Muirhead artificial cable. In this arrangement one plate or side of the condenser is used as a conductor, and it is joined in a continuous strip. The other plate is also joined in one continuous strip and is connected at both ends to the earth, figure 10, the strips being separated by the usual dielectric. The strip used as the conductor is so proportioned that it shall equal in resistance and electro-static capacity the cable of which it is the counterpart. This form of condenser is the one now almost universally used on long submarine cables.

One form of the Varley artificial cable was constructed of a plain resistance along which, at stated intervals, condensers were placed. The result of this arrangement, as shown by Varley himself, is that an irregular distribution of the charge occurs on the artificial cable. In a "main" cable the distribution of charge is regular from the maximum point of potential to zero. The Muirhead device therefore, provides an artificial cable more nearly corresponding to the "main" cable, than the Varley, or as it is sometimes called, the Stearns' artificial cable, and consequently permits a more perfect balance between the main and artificial cables, and increased efficiency in duplex telegraphy.

One of the first practical applications of the condenser of the sheet form was its use in the Ruhmkorff coil. Even as first constructed its beneficial effect in amplifying the

spark of the secondary coil and diminishing the destructive spark at the contact point of the circuit breaker was very marked. Although apparently simple of explanation none of the theories yet propounded as to the action of the condenser in performing this function, has, I believe, been definitely accepted as the correct one.

M. Fizeau, who suggested the use of the condenser in the Ruhmkorff coil, explains its action as follows: "As soon as the points of the interrupter are separated the two free electricities of the wire run into the plates of the condenser."

Faraday, Poggendorf, Hearder, Maxwell, Lord Rayleigh, and others, have given more or less divergent views of the action. As a sample of these various views, the following quotations will suffice: Gordon, Electricity and Magnetism, volume ii, page 44,—"When circuit is broken the extra current induced in the primary wire by breaking is in the same direction as the primary current, and therefore tends to prolong the magnetization of the core. When a condenser is used the extra current spends itself in charging it. The condenser instantly discharging itself sends a current in the reverse direction around the core and at once demagnetizes it." S. P. Thompson, Electricity and Magnetism, page 365,—"The object of the condenser is, firstly, to make the break in circuit more sudden by preventing the spark of the extra current from leaping across the interrupter, and secondly, to store up the electricity of this self-induced current in order that when circuit is again made the current shall attain its full strength gradually instead of suddenly, thereby causing the inductive action of the secondary circuit, at make, to be comparatively feeble."

This latter explanation seems to require that the charge shall remain stored up in the condenser until contact is again made, while there is a path left open to it *via* the

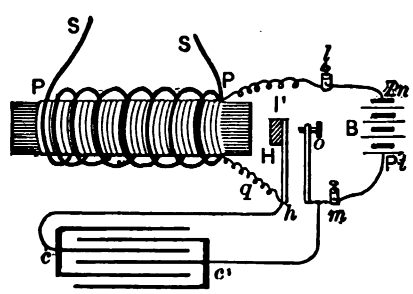

Fig. 11

battery and primary coil. See figure 11. The explanation quoted from Gordon seems to be the one most generally adopted, and it appears to be reasonably satisfactory.

This explanation may be given more fully as follows: Referring to figure 11, which is a diagram of the inductorium and condenser connections, HO are the hammer and anvil respectively, of the contact breaker, which is shown as open. The E. M. F. of extra current from the primary coil coincides in polarity with that of the battery B and both charge the condenser C. The extra current having exhausted itself, the charge in the condenser in excess of that due to the battery E. M. F. discharges through the battery and primary coil, demagnetizing the latter, and when the hammer again meets the anvil the remaining charge in the condenser is dissipated, leaving it again free to be acted upon by the combined E. M. F. of the battery and extra current.

The employment of the condenser to obviate sparking is of vast importance in printing telegraph systems, in which the currents are rapidly alternated by the reversing wheel or pole changer. Indeed without the condenser for this purpose the speed of transmission would be very materially reduced.

Another ingenious and useful application of the condenser, due to C. F. Varley, is that shown in figure 12. It was originally devised by Varley as a means of prolonging a signal which had been made by a momentary contact at the local contact points of the relay R. This the condenser C does by receiving a charge due to the difference of potential produced by the resistance of the recording instrument R′ at the moment of contact, and by discharging itself through the coil in the same direction as the current from the local battery B.

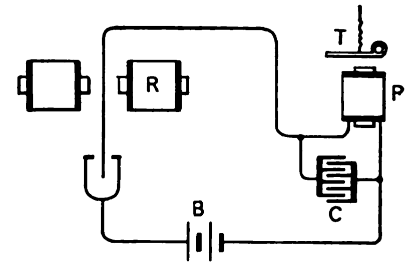

Fig. 12.

This principle is availed of also to advantage in the Delaney multiplex system of telegraphy in which the signals are made up of momentary contacts. It has also been used successfully in several automatic systems to prolong signals, and in quadruplex telegraphy for the same purpose.

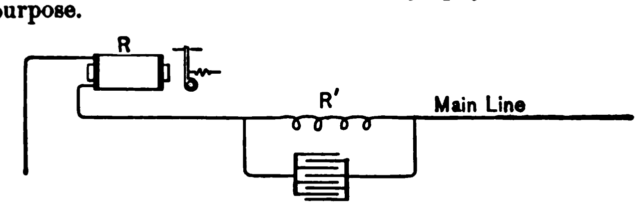

Fig. 13.

Another arrangement of the condenser (figure 13), is that in which its discharge is used in automatic telegraphy to reverse rapidly the magnetism of a relay, R. R′ is a plain resistance producing a difference of potential between the plates of the condenser. At the moment of reversal of the battery a portion of the discharging current at once reverses the relay R. A modification of this use of the condenser is also employed in quadruplex telegraphy to facilitate the reversals of magnetic polarity. The condenser has also been used in automatic telegraphy for the purpose of curtailing signals.

A very useful application of the condenser, which is also due to C. F. Varley, is that in which it serves as a repeater or translator of signals in simultaneous Morse telegraphy and telephony, in combination fire alarm telegraph and telephone systems and in simultaneous Morse telegraph systems using pulsatory currents, such as the Edison phonoplex, etc.

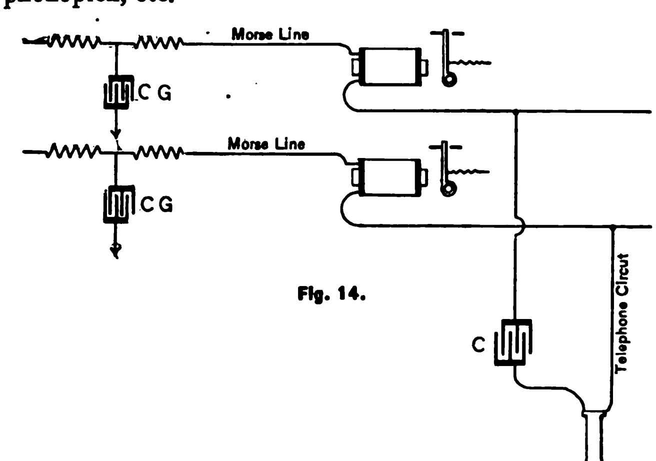

Fig. 14.

In these systems it not only acts as a translator of the signals but also prevents the grounding of the Morse circuits which would otherwise ensue, as when, for instance, a telephonic circuit is operated on a metallic circuit composed of two Morse telegraph wires, as shown in figure 14.

In certain methods of telegraphing to and from moving trains also, the condenser is indispensable. The same instrument is also of much value as a graduator of the telegraph currents in the Van Rysselberghe system of simultaneous telegraphy and telephony (C. G., figure 14). It has also been employed advantageously in this country as a means of preventing induction between parallel wires.

In the operation of long submarine cables the importance of the condenser is very great, and it is employed on such circuits in a number of different ways and for different purposes, as for example, to prevent the ill effects of earth currents, to avoid which, without the condenser or its equivalent, would necessitate the employment of looped cable circuits. In other words, the price of a duplicate cable for every existing long submarine line is virtually saved by the use of this simple instrument.

The most important and valuable application of the condenser, however, is probably to be found in its use as a static compensator in duplex and quadruplex telegraphy.

In the most successful systems of duplex telegraphy the home instruments are prevented from being sensibly affected by the home battery by means of certain arrangements of the apparatus (differential winding or the bridge method) and the employment of a so-called artificial line consisting generally of german-silver wire G, figure 15, which wire may be made to equal the main line in point of electrical resistance. This wire, however, has practically no electro-static capacity, and as this inequality of capacity between the main and artificial lines would tend to produce confusion of signals, the artificial line is given electro-static capacity, equal to that of the main line wire, by the attachment to it of a condenser or condensers in the manner indicated in figure 15.

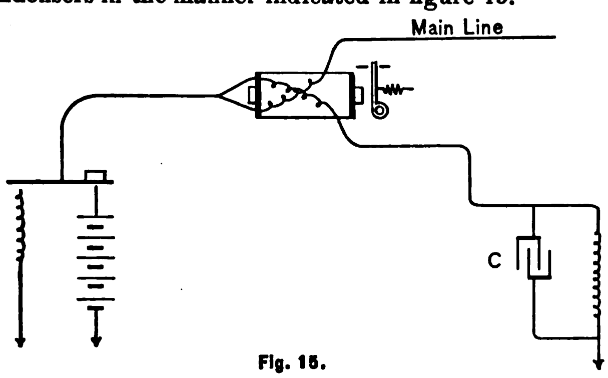

Fig. 15.

As previously stated, the Muirhead condenser used in long submarine cables is a nearer approach to the main line or cable in all respects than the usual condenser arrangement, but it is somewhat more expensive.

It is safe to assume that there is no substitute for the condenser as a "static compensator" in submarine cable duplex telegraphy, and no practically successful substitute for it in overland duplex telegraphy, and, further, it may be assumed that a large majority of the duplexed lines in this and other countries require a static compensator, and, therefore, the bulk of the duplexed circuits in operation would be practically inoperative without that instrument. On these assumptions the money value of the condenser as a static compensator may be estimated at millions of dollars.

The Baltimore and Ohio Telegraph Co. alone, by the use of this instrument, were enabled to operate many thousand miles of duplex and quadruplex circuits, which without it, could not have been successfully accomplished.

In electrical testing the condenser is also of great service, as in the measurement of electro-static capacity of cables; in the testing of joints; in measuring electromotive force; the internal resistance of batteries; insulation resistance by loss of charge; localizing breaks in insulated wire by capacity tests; in the nil method of testing resistances; and in measuring the resistances of batteries while working.

LIGHTNING ARRESTERS AND THE PHOTOGRAPHIC STUDY OF SELF-INDUCTION.[1]

BY E. G. ACHESON.

If in the opinion of any an apology is required—and it is thought that such will be the case—for thus presenting a subject that is in any of its parts a reproduction of the experimental work of such authorities as Professor Hughes, Professor Lodge, Dr. Hertz and others, the excuse is offered that the original motive for entering into the series of experiments referred to in this paper was a legitimate one, namely—the clearing away of a little fog surrounding some annoying phenomena attending the working of cables of electric conductors. The investigations became so interesting, so striking and suggestive, and some of the results appeared to have such a value, that it was believed they would afford sufficient excuse for this presentation.

While the measurements made during these investigations were not so accurate as it would be possible to obtain with more refined instruments, the probable errors were not so great as to make them wholly valueless, care in the readings and many determinations checking to a great extent the errors due to the crudeness of the apparatus. Appreciating the fact that untruthful results are less desirable than none, owing to their misleading effects, it is intended to impress the fact that the determinations contained in this paper can at best only serve as a possible guide for future work of a more complete and accurate character. It is also to be hoped that they may promote the already lively interest displayed by the scientific world in discharges, and the sometimes oscillatory character of electric currents.

The mass of material and composite character of the work to be presented will necessitate considerable care in selecting the order of presentation, and it is believed that the subject can be more easily followed if the thoughts and experiments succeed each other in the order in which they occurred to the experimenter, and this plan will be followed even when the after thought is of the greater importance.

As previously stated, the primary motive from which followed this series of experiments was the clearing up of some uncertainty as to the cause of a few annoying troubles in electric cables. But, to be more precise, it was desired to determine the cause of the occasional "grounding" and failure of cables used in telegraphic and telephonic service, when to all outward appearances they were perfect in construction, protected with lightning arresters, and immediately before the moment of grounding indicated high insulation resistances. A case of this kind presented itself for solution, in which there were some features of peculiar attraction to an investigator. It was a cable containing five wires about one mile in length, and of that design known as anti-induction, the cross-section being star shaped, each conductor having a surrounding wall of lead. It was used for telegraph work, and the conductors were connected at the ends to overhead lines, lightning arresters being provided for the protection of the cable; the terminals of the cable were on poles some twenty feet in height. The ground plates of the arresters were connected to the earth in the usual manner; that is, by wires running down the poles to plates in the ground.

This cable was continually getting into trouble, the conductors becoming solidly "grounded," and upon examination it was found that the "grounds" were caused by little kernels or spots of carbonized insulation. It was at the first moment thought that these had been introduced in the manufacture of the cable, but their repeated formation emphatically declared against this theory and made it imperative to learn the true cause. It was not probable that they were produced by the working currents, for they were of comparatively low electromotive forces, while the

1. Read before the American Institute of Electrical Engineers, at the College of the City of New York, Jan. 8, 1889.

presence of the lightning arresters would, in accordance with the prescribed rules of their action, render it wholly unlikely that they could have been produced by lightning.

A close study of the experiments of Professor Hughes on self-induction, and of Professor Lodge on the "alternative path" had produced an unsettled condition of my ideas as to the real value of a lightning arrester. The work of these investigators, together with some few experiments of my own, had produced a feeling of interest as to the efficiency of even the best arranged arresters as connected in ordinary practice. I was prepared to believe this to be a practical live case of a well-mounted and connected lightning arrester not protecting. It even seemed possible that the cable itself was, in reality, protecting the protector, when viewed in the light of Professor Lodge's "alternative path" experiment.

In order to come to some definite and practical conclusions as to the possibility of these troubles having been produced by lightning, a series of experiments was undertaken on lines somewhat analogous to those of Professor Lodge.

In figure 1, the general and important conditions of a cable placed in the earth and provided with lightning arresters as usually connected, are outlined. In the figure K represents the cable, L the line wire, and W the ground wire connecting the protector C to the ground plate G.

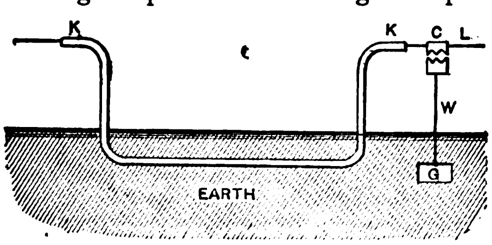

FIG. 1.

It is generally supposed that lightning—or an electrical discharge, as I prefer to call it—produced by the difference of potential between the cloud above the wire L, and the earth beneath, would, upon striking the wire, pass to the lightning arrester C, jump across the space separating the points to the wire W and thence to the earth, or the reverse, as the case may be. But while this is probably the case in many instances, it has not yet been satisfactorily demonstrated that there have not also been many cases where this plan of procedure was materially departed from, the discharge making a path for itself through the cable and the insulation, or perhaps dividing itself between both routes. In order to obtain more clearly defined ideas of

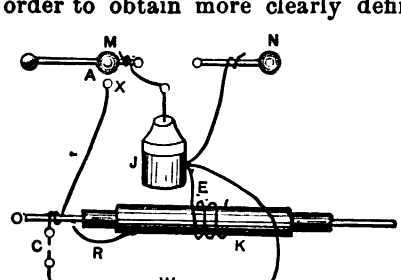

FIG. 2.

the action of a discharge under these conditions, the apparatus shown in figure 2 was used, in which it will be seen that the fundamental features and the connections of figure 1 are reproduced for experimental work, the cloud being represented by the inner coating of the Leyden jar J, and the earth by the outer one, the charge being produced by a Holtz machine, of which M and N are the conductors. The long length of the cable in figure 1 is replaced by a short one, K. As before, L represents the line wire, and in this case is connected directly to the conductor O in the cable. The lightning arrester, is replaced by an equivalent, C, composed of two points separated an appropriate distance. The wire W is, as before, the ground wire connecting C in the former case to the earth, and in the latter to its equivalent, the outside of the jar; the lead covering of K is also connected by means of a short wire to the same outer surface. While in figure 1 the point on the line L which is struck by lightning is subject more or less to accidental conditions, it is in the case of figure 2 selected and adjusted by the ball X, as is also the value of the energy of action, by the areas of the surfaces on the jar J and the length of the striking distance, A.

With the apparatus arranged as just described and illustrated, it was quickly determined that a discharge could with great ease be caused to pass through the insulation of the cable, even when the space C was but a fraction of the distance through the insulation, and the length of W a few inches of stout copper wire. The current of discharge seemed to divide itself, a portion passing by W producing a spark at C, and another portion passing through the cable. A few more experiments also demonstrated that

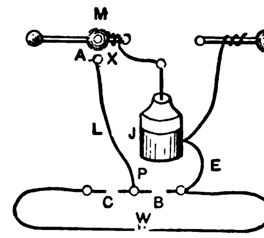

FIG. 3.

the wire W had apparently as much influence on the results as the space C, and consequently it became necessary to analyze the combination more completely to determine the relative values of C and W. With this object in view, the cable K was thrown out of the combination, and the connections simplified to those shown in figure 3. On close examination they will be found to be in every way similar to those in figure 2, with the exception of the replacing of the insulation of the cable K with a clear air-space B, and instead of connecting L to the conductor O it is here connected to a post P. The spaces C and B were both adjustable to a fairly accurate degree, B being easily readable to thousandths of an inch.

The system of experimentation was to take a certain length of wire, W, adjust A and C to known values, and then adjust B so that one spark would occur there for about every ten at A, and after having noted the length of the spark B a few inches would be cut off from W and B readjusted and again noted; this being repeated until W was wholly consumed. The values of B for these various lengths of W and a known length of C having been obtained, a wire similar to the original W was substituted for the former, and C having been removed from the circuit, as shown in figure 4, a similar set of tests were made, and the

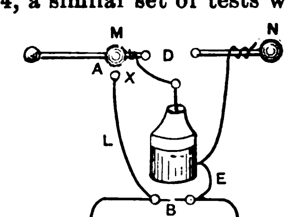

FIG. 4.

differences between the results, with and without C, indicated the true values of C and W in the combination, while the results with W alone show the value of each additional inch.

In plate A the results of these measurements have been plotted into curves. The length of W in inches is plotted horizontally while B in thousandths of an inch is laid out vertically. The capacity of the jar J was .0025 M. F., and A was retained uniformly at .286 of an inch. The full line curve is that of W without C in the circuit, while the

dotted one is that obtained with it in. The length of C was .02 of an inch. W for both tests was composed of a copper wire having a diameter of .052 of an inch.

A brief study of these curves teaches that, when W is but a few inches in length, C plays a very important part in determining the length of B, and also that its influence rapidly vanishes as W is lengthened, and actually produces an opposite effect after a certain length of W has been arrived at. Thus, with W 20 inches long, C has a value equal to 59 per cent. of the total circuit, at 110 inches it appears to have no value, while at 180 inches the value of the compound circuit is about 7 per cent. less than W alone. These

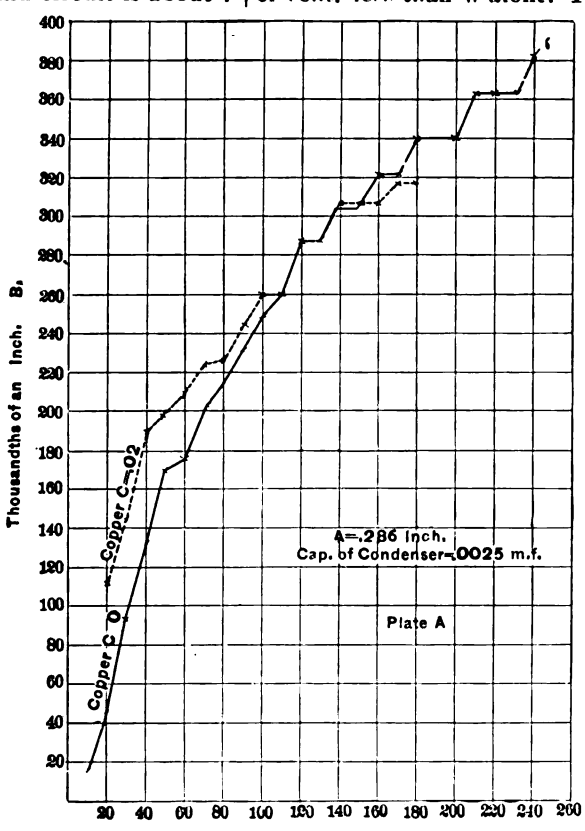

PLATE A.

points are, however, of even less importance than the lesson to be learned from the study of the curve of the results obtained with W alone. Here is a case where a relatively small amount of energy contained on the surfaces of the jar J will, when discharged into the circuit composed of the air space A and the wires L, W and E cause the passage of energy in the form of a spark at the point B of a length of over one-third of an inch, and this when the wire W is but 20 feet in length, or that of an ordinary ground wire down a telegraph pole.

This does not look very encouraging for lightning arresters with long ground connections, and rather puts to ridicule the fine adjustment of the points of these devices. The subject will, however, stand more than a little study and investigation before forming judgment, and perhaps the arrester is all right after all, in so far as the close adjustment is concerned, even if the long ground connection does have to go.

Those who are familiar with the recent investigations of Professor Lodge, investigations so exceedingly interesting and now so celebrated that few there are who have not made themselves familiar with them, will at once have recognized in figure 4 connections very similar to those used in the experiment of the "alternative path," by Professor Lodge. The results obtained by him and in the present experiments are in the main the same, and those differences that do exist are probably to be attributed to the following facts: Professor Lodge's work was done with instruments of great precision, the sparks were always produced between balls or rounded surfaces, and the object was to determine laws and formulate their mathematical expressions; while, on the other hand, the experiments now being described were made in some cases under the most difficult conditions, with apparatus limited to a most exceptional degree both in quality and quantity, a certain portion of the sparks were produced between points, and the object in view was to dissect, analyze and subjugate the phenomena under examination to and for the benefit of practical work, the every day affairs of the electrical profession.

It is, however, exceedingly difficult to avoid a little speculation, now and then, as the subject unfolds itself, and it is hoped the experimenter may be pardoned for any references that may be made to the theories that have been the immediate cause of some of his researches. It is even hoped that the work performed may atone for the views about to be advanced, notwithstanding the fact that they are quite contrary to those deduced by so high an authority as Professor Lodge.

After a considerable portion of this work had been done and the conclusions more or less formulated, I was much pleased and greatly strengthened in the opinions then being formed to learn through a letter from Professor Hughes to Professor Lodge, published in the London *Electrician*, issue of Sept. 28, 1888, that Professor Hughes had, at least formerly, held the same views of the "alternative path" that I had formed, and which will now be presented in connection with what is thought to be experimental demonstration of their truthfulness.

Referring to figure 4, it will be seen, as has already been stated, the conditions and arrangements of W and B are such as to produce and actually constitute the "alternative path," as shown by Professor Lodge. The simple assertion that they are alternative paths does not, however, make them such, and, while they may under certain conditions and adjustments become so, it is possible to conceive of their being otherwise. It is not beyond the bounds of reason to assume that the energy that has been discharged from the jar J, traversing the wire W, produces in it a condition that may be termed *electrification;* and on the disappearance of the controlling influence of this energy, would not the wire W return with an almost infinite rapidity to its original non-electrified condition, and, in doing so, produce as the result of this enormous rapidity of motion, an electromotive force at its terminals of a greater value than that of the original energy? In other words, will there not be a restoration of the energy expended in distorting the lines of energy within the wire, and this restoration being performed in a shorter interval of time than that occupied in its production, will not a higher electromotive force be obtained even though the value of the return would be less than that of the original, to an extent equal to the losses due to the internal friction of the mass?

This being the case, this current of discharge from the wire,—which was first discovered by Henry and investigated by Faraday and called by him the *extra current*—would, owing to its greater electromotive force, jump the space B and thus close its circuit, even when the distance was such as to prohibit the passage of the original current as discharged from the jar J.

It seems as though this might be the case, and, if it is, then the discharge that was obtained through the insulation of the cable in figure 2 need not have been a part of the original current from the jar J, but the current discharged from the wire W. If it was, a shortening of W would tend towards overcoming the difficulty. To test the case a short wire R was attached to the lead and bent out over the insulation so as to present a point to the conductor O, the distance between the point and the conductor being about the same as the thickness of the insulation; W was now removed, as was also C. It will be seen that E, the lead of the cable K, the short wire R and the space separating its end from the conductor O, form an equivalent to W

and C. With this arrangement it was not possible to cause a discharge to pass through the insulation.

Now, in accordance with the views which have seemed to me most probably true, this change is due to the reducing of the length of the path W, and which is now composed of R, E and the lead of the cable, this reduction resulting in a subsequent lowering of the potential of the extra or self-induced current. But if the theory of Professor Lodge's "alternative path" is correct, then the change would be due to a removal from the path W of a certain amount of resistance, which has been termed by Mr. Oliver Heaviside, *impedance*.

We here have an apt illustration of inertia under the American and English definitions, as so forcibly stated by Professor Ayrton. As I have presented it, the spark B is the result of inertia, with the American definition—a resistance to stopping. While Professor Lodge's theory would account for it by inertia with the English interpretation of that word—a resistance to motion.

Accepting the belief that the spark B, when adjusted to the critical point, was caused by the self-induction of the wire W, a variety of experiments were made with the desire of obtaining experimental proof of the theory. Repeated occasions presented themselves for mathematical work, and if time and attention could have been given in that direction, the results would unquestionably have been of interest and value, but the work was perforce restricted to the more limited confines of experiment and reasoning. The first experiment of the series was to replace the wire W in figure 4 with one of smaller diameter, and re-determine the value of B in the manner already used for a copper wire having a diameter of .052 of an inch, and of which the results have been plotted in plate A.

Before presenting the experimental results, it is desirable to consider what might be expected from these changed conditions. There will in all cases be practically the same amount of energy discharged into the circuit, for the areas of the condensing surfaces on the jar J remain constant, the length of the striking distance A also remains uniform, and while it is true that the resistance of W, as measured by a Wheatstone bridge, would vary inversely as the square of the diameter, the resistance of the complete circuit of discharge is, owing to the air space A, practically infinite, and hence the relatively trifling resistance of W, even when of the finest wire, may be wholly neglected.

The theory that the self-induced or extra current in a wire is a recoil action, is based primarily upon the hypothesis that there exists, before the electrifying current is discharged into the circuit, a prior state—the *electro-tonic* state of Faraday. This *electro-tonic* condition consists in the existence of lines of energy—thermal they may be—with directions coinciding with the radii of the wire; these lines or axes of energy being surrounded by circular lines of magnetic force. An electrical current being discharged through such a wire would cause, under the influence of its well-known magnetic whirls or circles, whose planes are at right angles to the line of propagation and in this case to the axis of the wire, a deflection of the planes bounded by the closed lines of magnetic force surrounding the radial lines of energy which are within the wire. The work of producing this deflection would, I think, constitute what is known as the variable resistance which meets a sudden discharge, and which was made the subject of that grand paper on "Self-Induction" by Professor Hughes before the Society of Telegraph Engineers, at their meeting of Jan. 28, 1886. This deflecting of the radial lines of energy, while constituting a resistance to the inducing current, is also, the source of, or rather, during the act of deflecting, produces, an electromotive force contrary to that of the inducing current. This counter electromotive force exists only during the interval of deflection, and quickly vanishes from the path of the inducing current. On the moment of the interruption of the inducing current, and consequent withdrawal of its attending magnetic whirls or circles, the deflected radial lines of energy swing back to their radial positions, producing by their motion an electromotive force of such a direction as to form a current in the same direction as that of the inducing current. This return swing or recoil, as of a spring suddenly released, is of such a velocity, and overlapping, probably, what might be likened to the tail end of the disappearing inducing current, produces a momentary electromotive force of a value higher than that of the original current. These being the actions of the forces and energies, it now becomes necessary to understand what differences, if any,

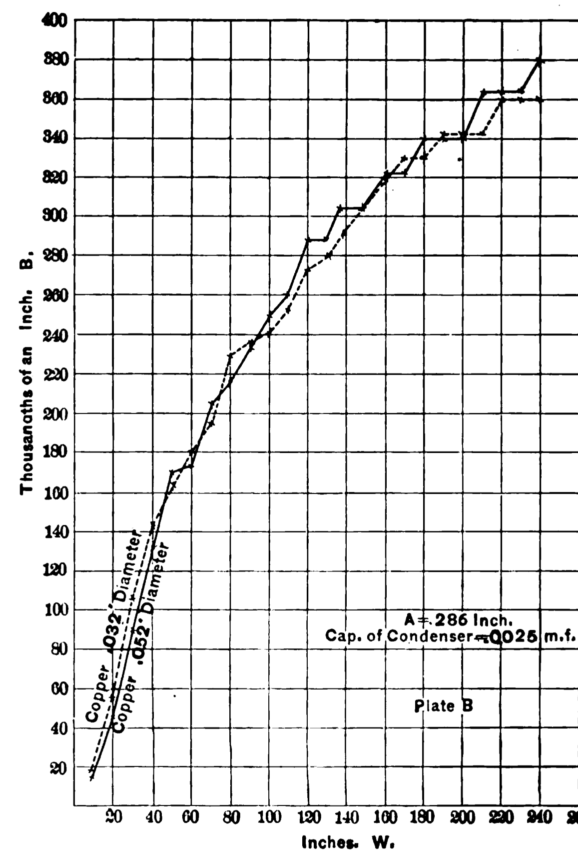

PLATE B.

the size of the wire through which the original current is discharged will have upon the value of the induced, or, as it is more generally termed, the self-induced electromotive force. All of the experiments and considerations will be made under the conditions of a constant capacity for the jar J and uniform length of A, and consequently one value for the energy discharged into the circuit. In all cases there will, of course, be a certain amount of the energy that has been discharged into the wire lost and converted into heat. This lost energy will be greater in value in the smaller wire than in the larger in a proportion inversely as their diameters. This greater loss in the small wire and resulting reduction in the available inducing energy would, of course, tend to produce a diminution of the self-induced current. This reduction is, however, exactly offset by the greater concentration of the inducing energy, its inducing value having been increased in a proportion inversely as the diameters of the wires.

It is feared this argument has become tiresome, and an immediate relief will be found in plate B, where I have plotted two curves; one, the full line curve, is the same as that shown in plate A, and was produced as formerly stated. The dotted line curve was made with a wire of copper having a diameter of .032 of an inch. The two curves are so nearly alike as to permit of the belief that they are in reality the same, and that the slight differences existing are due to errors of measurement. Here is experi-

mental proof that the electromotive force of the self-induced current, as measured by the spark B, remains constant as long as the energy discharged into the circuit is of uniform value, and is wholly independent of the diameter of the wire, and this seems to give countenance to the argument immediately preceding.

It is more than probable that those who have been following the subject closely will, before this time, have had the question asked, from somewhere within: "How would these curves on plate B have looked had one been made with an iron wire?" The answer is ready at hand on plate C. It is not exactly an answer to the question as stated, for there are here shown two curves, one produced with an iron wire and the other with a copper wire, but both are of the same diameter, .052 of an inch. The curve of the copper wire is the one you are already familiar with.

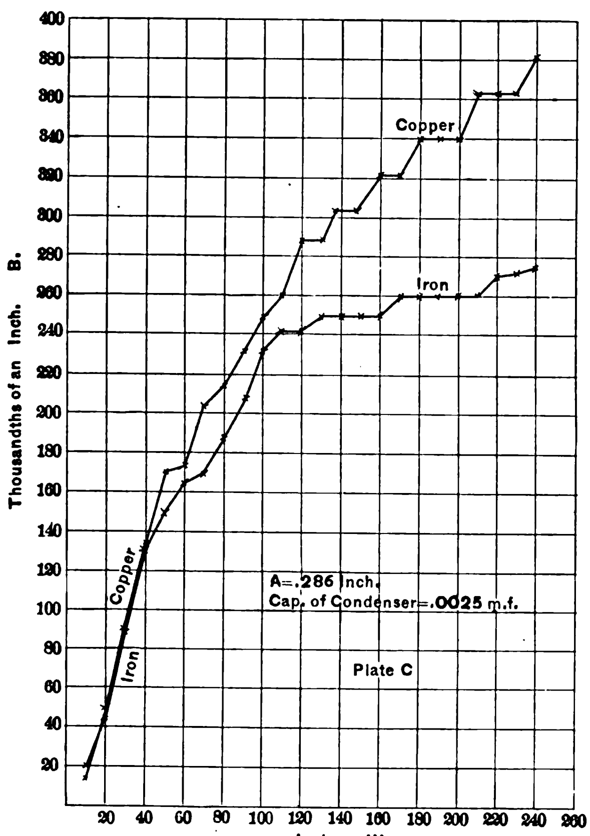

PLATE C.

This paper has even now attained to such proportions, and there are yet so many points to present, that nothing more than a moment's glance at these curves can be offered. A study of them teaches that for lengths of 40 inches, copper and iron will, when acted upon inductively by discharges of one value, furnish self-induced currents of like electromotive forces. From 40 to 110 inches they show slightly different values, while beyond this length their efficiencies rapidly diverge; that of the iron running much lower than that of the copper, and apparently fast approaching a maximum. As a means of accounting for these different efficiencies, I would suggest this theory. Up to 40 inches of length the time occupied by the passage of the discharged current was too short to permit of any magnetic effects occurring in the iron, and consequently the wire was equivalent to its neighbor, the copper; from 40 to 110 inches small magnetic effects were produced, resulting in a lag or retardation of the velocity of the recoil deflection of the radial lines of energy, and resulting, of course, in a lowering of the electromotive force of the self-induced current; beyond 110 inches, the time of discharge rapidly increased in duration, and thereby produced the decided flattening of the curve, as shown.

There is one more set of curves to present: They are shown in plate D, and were made with the object in view of determining the effect of a variation in the amount of energy discharged into the circuit. Experiments were made with both copper and iron wires; the curve of the copper is plotted in above that of the iron one. In the plate, the capacities of J in millionths of a microfarad are plotted horizontally, while the lengths of the B sparks in thousandths of an inch are plotted vertically. The length of the A spark was, as before, .286 of an inch. I was prepared

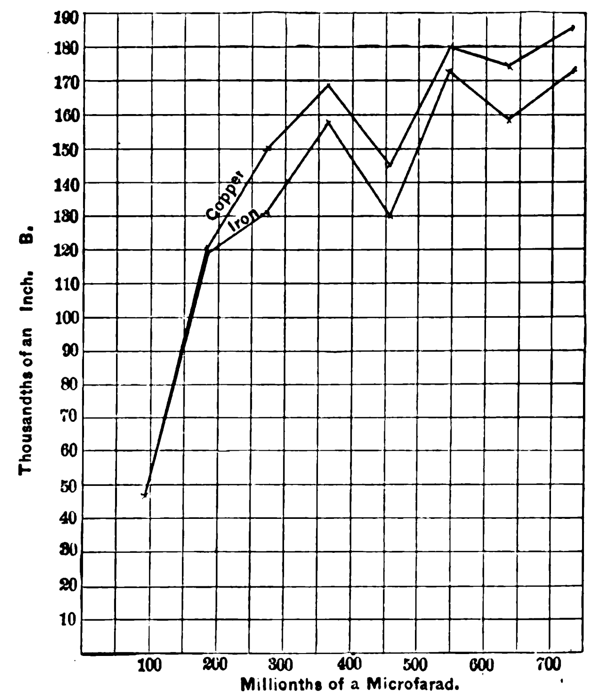

PLATE D.

to see the B spark increase as the energy discharged increased; but I was wholly unprepared to have it decrease as the result of added energy after a certain point had been arrived at, and still less prepared to obtain the wavy curves, as shown.

Time will not permit of entering into any consideration of the peculiarities of these curves.

There is a little experiment, the record of which I wish to interline at this point; it may answer a question, and perchance wet the powder of some intending questioner. Looking over my sketches and coming to figure 3, the thought struck me that an error might have been introduced into the experiment where the C spark formed a part of Professor Lodge's "alternative path," due to there being no connection having other than an infinite resistance between the ball X and the outer coating of J, while in all of the other experiments there was the circuit formed by W. It seemed possible that this change might have produced a different value for the energy of the discharged current, as the difference of potential between M and X might be altered. To decide the question, the connections as shown in figure 4 were used. The balls forming the terminals of the Holtz machine were caused to approach each other until the discharges occurred about an equal number of times between them at D and at A. Next the space B was adjusted to the critical length. If the existence or non-existence of the wire W and resulting metallic connection between X and J influenced the value of the potential of discharge, its removal ought to lower the potential difference between M and X, and cause all of the discharges to occur at D. The experiment, however, did not prove this to be true, the removal or replacement of W having no apparent effect upon the number of the discharges that occurred at A and D; but, of course, when it was removed every spark at A caused one at B.

A few experiments were now made to determine the effect various portions and positions of the parts of the wire W would have upon other portions of itself. The connections shown in figure 4 were used. A length of 50 inches of cotton-covered copper wire, with a diameter of .033 of an inch was used for the wire W. It was arranged in the form of a circle. A was, as before, .286 of an inch, and the capacity of J was .0025 M. F. The critical point of B was found for these conditions, and W was then formed into a figure whose two sides were parallel, and B was measured for various distances between the two sides. These distances were, however, only approximate.

Position of W.		B in inches.
Circle		.182
Sides separated	3¼ inches	.170
	2½ inches	.137
	2 inches	.137
	1½ inches	.137
	1 inch	.137
	½ inch	.114
	⅛ inch	.050

The next experiment, illustrated in figure 5, was to take the same wire, W, and coil it upon a paper tube having a diameter of ¼ of an inch, the wire forming a spiral of one layer about two inches in length. This spiral being placed in the position W the critical point of B was found to be

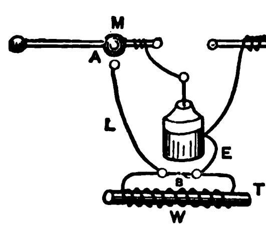

FIG. 5.

.197 of an inch, or over 8 per cent. greater than when the wire was in a circle. While the spiral was in the last position an iron wire one-tenth of an inch in diameter was inserted into the paper tube, and now the spark B only measured .170 of an inch, over 13 per cent. less than without the iron wire, and more than 6 per cent. less than the plain circle. Another experiment was made like the last, with the exception that the iron wire was long and bent around into a closed circuit, but it did not alter the results. The lowering of the value of the self-induced current upon the introduction of the iron wire was to me at the time startling, but a consideration of the case showed that it should be so, for a portion of the energy of the inducing current was absorbed in producing work in this mass of iron, and of a necessity weakened the self-induced current to an extent measured by the work this extracted energy could and would have done in the wire W had it not been withdrawn. I have, however, here a confession to make. I was all of the time considering that this energy was expended in producing magnetic effects in the iron wire until a friend who had called to see some of the experiments suggested that I insert a copper wire instead of the iron one. I did so. The effect was the same as that obtained with the iron wire. The explanation was simple: It was that not magnetic effects, but electric currents, closed upon themselves within the wire had been produced. The reduction of the length of the spark B now became a simple question of causing the inducing current to do more or less work external to the wire W, and as another means of causing it to do so, the spiral was surrounded by another spiral of wire, with the ends so arranged that they could be connected or opened as wished. With this arrangement, the spark B could be made to come and go, as desired: for by adjusting it to the critical point with the terminals of the outer spiral open, it would entirely disappear when they were united, all of which agrees perfectly with the former experiments and conclusions.

Another short series of experiments was conducted with parallel circuits, as shown in figure 6. The lengths of the parallel portions were 35 inches, the distance separating them being .052 of an inch. The total lengths of L and W were 130 inches. A and J were of the same values as heretofore used.

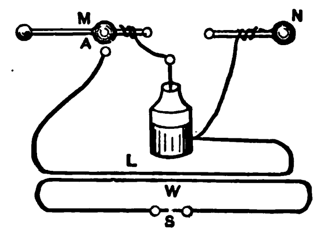

FIG. 6.

The conditions of the tests and the resulting lengths of the spark S may be briefly stated thus :—

Test No. 1..	L was	copper,	diameter .052 in.		S — .031 in.
	W "	"	"	"	
Test No. 2..	L "	"	"	"	S — .024 in.
	W "	iron,	"	"	
Test No. 3..	L "	"	"	"	S — .020 in.
	W "	"	"	"	
Test No. 4..	L "	"	"	"	S — .025 in.
	W "	copper,	"	"	

If my memory serves me right these results are the same, qualitatively, as those obtained by Professor Hughes, and clearly show the apparent sluggish action of iron, both in imparting and receiving magnetic inductive effects. Its relations to these magnetic effects resemble the actions of a polished metal surface when associated with heat; it radiates and absorbs poorly.

It now becomes my pleasant duty to present the concluding and, at the same time, most interesting and convincing proofs that W is not an "alternative path," but that the spark B is produced by, and consists of, the discharge of the self-induced current. I have called this series of experiments

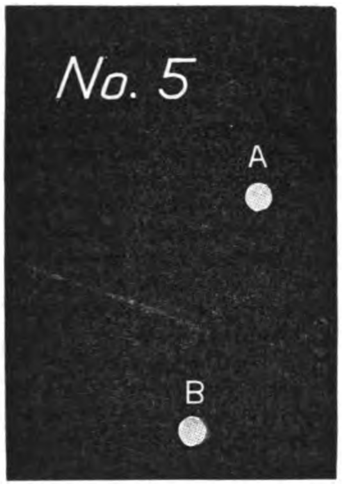
THE PHOTOGRAPHIC STUDY OF SELF-INDUCTION.

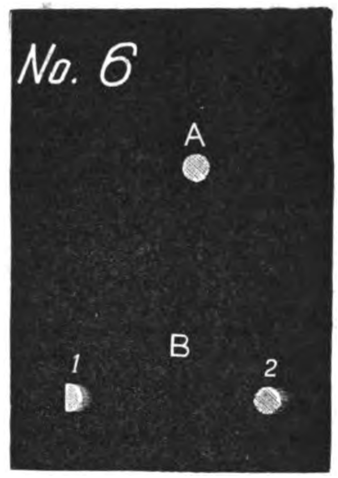
Unfortunately, at a late day, a day so late as to prevent my repairing the loss, I met with at least two accidents, and each of them cost me one or more negatives which were a part of the record of these experiments. I shall, however, endeavor to make those remaining demonstrate the desired points.

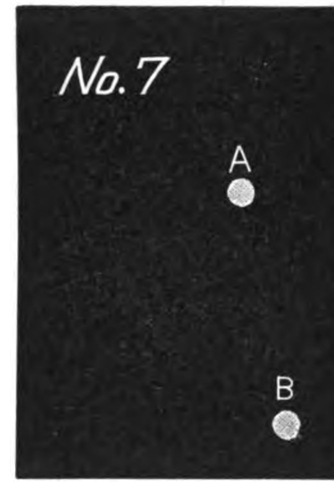
In making these experiments the end in view was to obtain photographic records of the duration of the spark A, with and without the spark B; with and without the wire W; with various lengths of the wire W, and, if possible, to detect a difference of time between A and B. A disc of tin plate, 20 inches in diameter, was mounted on an arbor and belted to a system of pulleys of such sizes that by working the train by hand a velocity of about 75,000 inches per minute could be given to a circle of holes that had been punched in the disc at a distance of one inch from its edge. These holes were about one-eighth of an inch in diameter and one inch apart from centre to centre. The disc was so placed in relation to the positions of the A and B sparks that a line stretched from A to one of the holes in the upper edge of the disc would pass through B. Immediately back of this same hole a sensitive plate was fixed so that the hole was in front of the centre line, while the plate was removed sufficiently far to avoid being touched by the disc. One-half of the sensitive plate projected above the edge of the disc; this upper portion was covered with a tin plate in which a hole was punched of a size similar to those in the disc. The lower portion of the sensitive plate—that is the part back of the disc—was also covered with a tin plate in which a window had been cut a little over one inch square, and in such a position that the holes in the disc passed in front of it. It will be understood from this description, that

while the disc revolved there could be two holes in front of the window, while there could not be less than one. With these adjustments sparks at A and B, separately or united, would produce an impression upon the sensitive plate, through the upper hole, and through one or two holes, as the case might be, in the revolving disc.

The B spark was adjusted to a point near the critical state, but, owing to the necessity of its production with the first A spark, it could not be set to the same delicacy of action as heretofore. The photograph shows a slightly blurred or indistinct outline on the right-hand side of the spot B, which is more clearly brought out by comparison







As a result of the accidents above referred to, it will be necessary to introduce the series of experiments with photograph No. 5, where we have the spot produced through the hole in the upper stationary screen marked A, and a spot lower down on the plate marked B, and which was produced through one of the holes in the revolving disc. The object in having the spot A was that it might offer a means of comparison between impressions made through stationary and moving apertures, and also show the effect of vibrations, if any existed, in the various parts of the apparatus. The value of the energy discharged through the circuit from J was disregarded, care, however, being taken that there should be no change in it throughout the entire series of experiments. The velocity of the apertures or holes in the disc was fairly, but not absolutely, determined to be 75,000 inches per minute. With this velocity of movement, a displacement of the apertures of one thousandth of an inch would represent an interval of time equal to $\frac{1}{75000000}$ part of a minute.

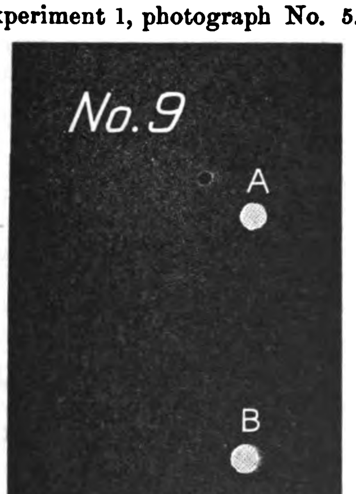
The series of experiments will be divided into four sets as follows:

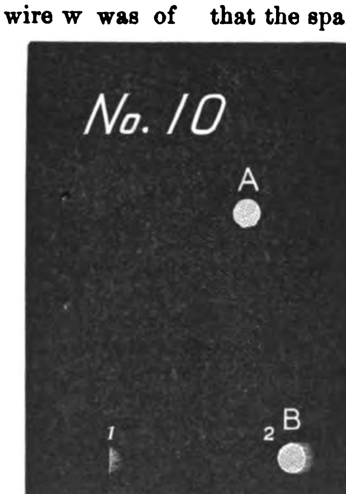
Experiment 1, photograph No. 5.—The wire W was of copper, 76 feet long and .052 of an inch in diameter, the spark A was $\frac{5}{16}$ of an inch and was retained at this for the entire series.

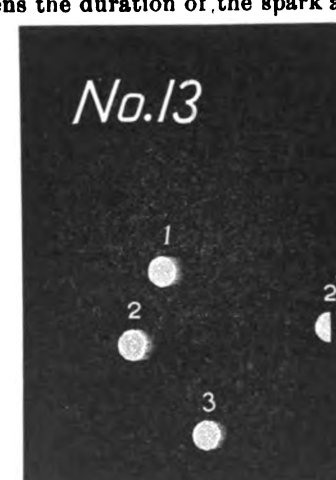
with the spot A. From this it is concluded that a measurable length of time was occupied by the spark, as the aperture in the disc through which this B spot was produced must have moved an appreciable distance in order to have produced this elongation or "ghost," as the photographic profession would term it. Owing, however, to the absence of any displacement of the distinct outlines of the spot, it cannot be assumed that there was any difference in the time of A and B, or, at least, not of sufficient value to permit of measurement with this apparatus.

Photograph No. 6.—In producing this photograph all of the conditions remained the same as those used in photograph No. 5 with the one exception of the spark B, which was removed from the circuit by separating the points beyond the striking distance. Here by chance two holes, or rather one and a half, were in front of the window at the moment of sparking, and produced the spots one and two. These spots exhibit displacements that, roughly measured on the negative, are one-tenth of an inch in length, and show a duration of the spark of not less than $\frac{1}{750000}$ of a minute.

From these two photographs the conclusion is drawn that the spark B shortens the duration of the spark at A.







Experiment No. 2, photograph No. 7.—The conditions of the circuit in this case were: Wire W shortened to 20 inches in length; spark B still out of circuit. This photo

graph shows about the same length, but a darker "ghost" following the spot B than did photograph No. 6, and indicates a corresponding increase in the *work done at* A.

Photograph No. 8.—The conditions are the same as the last, excepting that the B spark is again introduced. While there is still a measurable duration to the spark, the shortening of the interval due to the spark B is very decided.

Experiment No. 3, photograph No. 9.—In this experiment the entire apparatus associated with the spark B was cut out and the outer surface of the jar J was connected by a short copper wire to the ball X (refer to figure 4). An examination of the photograph indicates that A existed for an interval of time approximately equal to that of the last experiment (photograph No. 8) and very much less than that shown in photographs Nos. 6 and 7.

Photograph No. 10.—In this case the wire W was removed and the spark B adjusted to about $\frac{5}{16}$ of an inch. There seems to be, possibly a very slight increase in the time over that of photograph No. 9.

Experiment No. 4, photograph No. 13.—To this photograph special attention is invited. The conditions under which the negative was produced were wholly different from the foregoing. The tin plate covering the upper half of the sensitive plate, and which carried the aperture through which the spots A were made was removed, the plate was lowered, so that a point represented by the spot marked 1 came on a line with the apertures in the disc. The wire W was composed of 50 inches of cotton-covered wire like that used in some of the earlier experiments, and was formed into a circle. The B spark was removed and was not used during this set of experiments. The A spark was, as before, $\frac{5}{16}$ of an inch, and the spot 1 in the photograph is its impression through an aperture of the disc, and, as readily seen, shows a very considerable duration of time.

The sensitive plate was now elevated a little, the wire W was coiled into a spiral, as described in a former experiment, and the spark A was once more caused to pass. Spots 2 and 2′ are the impressions produced by it, and, as will be seen by close inspection, exhibit longer "ghosts," and consequently a greater interval of time, than was shown in spot 1. Once more the sensitive plate was moved upwards, and an iron core having been inserted into the paper tube upon which W was coiled, the spot 3 was produced by another spark, the "ghost" produced being smaller than either of the former ones. These three experiments show conclusively that the presence of the wire W in the form of a loop or circle in the path of the discharged energy, tended to prolong the action upon the sensitive plate; next, that the coiling of the wire into a spiral increased the duration of that action, and lastly, that the introduction of the metallic core into the coil, and consequent stealing away of a portion of the discharged energy, shortened the time of action to an interval less than that of the loop.

The field opened up by these photographs for theorizing and speculating is a very broad and rich one, but the time is now too short to more than indicate the manner in which these results add strength to the conclusions deducted from the former experiments. Applying to the photographic experiments the theory already advanced, that the B spark was a discharge from the wire W, it is found, as would be expected, that when B is absent the self-induced current discharges into the jar J, producing in its passage a spark at A; this spark following immediately upon the heels of the original A spark. The jar being in this manner recharged, but, of course, in the opposite direction and of a slightly lower potential, will again discharge into the circuit—the discharge at a reduced potential being facilitated by the thermal and, possibly, magnetic conditions of the air space A, and which were produced by the first spark.

This second discharge will leave the jar J once more charged, and will be followed by other discharges of a continually decreasing value, until the energy has been dissipated as heat or into other forms of energy through and by the various portions of the circuit. This subject of the oscillating discharge has lately received, at the hands of Dr. Hertz, a masterly and most highly interesting treatment.

Referring once more to photograph No. 6, which was produced by an A spark with W, composed of a copper wire 76 feet in length, the impression produced by the original, or first spark, is clearly defined, while in its wake is traced the track left by the sparks produced by the rapidly weakening, oscillating, self-induced currents—a track fading away like the tail of a comet, to an invisible end.

The next step in the inquiry is to determine the effect of introducing the spark B, and for this purpose reference will be made to photograph No. 5. Here we find, as would be expected, that the comet-like tail has almost disappeared, the natural result of having offered the self-induced currents from the wire W, a means of short-circuiting themselves across the points at B. The slight trace of a tail—a blurred outline—is to be attributed to the self-induced currents of the portions of the discharge circuit lying between the points of B and the surfaces of the jar J.

Shortening the wire W, with the spark B removed, should have the effect of increasing the amount of energy dissipated in the air space A, and further than this there should be little or no alteration. This increased amount of dissipation at A may be popularly explained thus: The total circuit into which the energy contained in J is discharged, and which consists of the space A, the wire W and the connecting wires, constitute the bodies or spaces from which the energy is radiated or dissipated, and, therefore, any contraction due to removing a portion of them will, of necessity throw more work upon the parts remaining. That this is correct is illustrated by photographs No. 6 and No. 7, where the conditions were the same other than a shortening of W from 76 inches in No. 6 to 20 inches in No. 7. A comparison shows that while the length of the "ghosts" are practically the same, that of No. 7 is heavier—more material. In the same manner in which the work was increased in the space A, so will it be increased in the wire connecting the points at B to the surfaces of the jar J, and for this reason the introduction of the spark B should not be expected to cut off the tail from the spot B to the same value obtained with a long wire at W. This is the case, as is shown in photograph No. 8, where W is 20 inches and B has been returned to the circuit. If the "ghost" shown in photograph No. 8 was due to the self-induced currents in the connecting wire, as has been assumed, then the same results should be obtained by cutting off the entire portion of the circuit represented by W and the apparatus associated with the B points, and short-circuiting these connecting wires. That this is the case is shown in photograph No. 9.

Cutting out W and replacing B did not seem to alter the results, very much, if any, from those last mentioned, and this is just what would be expected.

In photograph No. 13 it is demonstrated that the coiling of a wire into a spiral tends to cause a retension of the energy within itself, and is due probably to the gathering up of a portion of the energy radiated or dissipated by one convolution by the adjoining convolution, and thereby restoring it to its own mass. This retarding of the process of dissipation will result in a prolongation of the time of A and consequent action on the sensitive plate, as is shown by the increased length of the "ghost," following spots 2 and 2′ over that following the spot 1. As would be expected, the length of the "ghost" is immediately contracted upon increasing the rate of dissipation of the energy as results from the introduction of a metallic core in the coil of W, as is illustrated in spot 3.

The final conclusions to be drawn from these experiments are :—

1st. The "ground plate" of a lightning arrester should be connected to earth by as short a connection as may be possible.

2d. When an air line connects to a cable, a lightning arrester should be provided and attached to the armor of the cable by a connection not more than a few inches in length.

3d. When a short "ground wire" can not be used, one formed of a number of strands may be used, preferably not twisted into a cable.

4th. Any method by which a portion of the discharged current which passes over the "ground wire" may be withdrawn, will tend to increase the efficiency of the arrester.

5th. Under conditions similar to the tests, copper or iron may be used with equal efficiency, when the lengths are under forty inches, and over this length iron is more efficient than copper.

6th. The resistance of the "ground wire" is of little consequence, but it should have a size sufficient to carry off the charge without overheating.

7th. The insulation in a cable may be punctured by lightning, either by the direct discharge, due to the points of the arrester being too far apart, or by the current of self-induction from the "ground-wire," when that wire is of any considerable length.

8th. Dissipation of the energy of discharge reduces the self-induced current.

POINTERS.

.... IF the engine runs very slowly it is a comfortable thing for the man in charge; it is not so comfortable for the man who has to pay the coal bill.—*Gisbert Kapp.*

.... I WAS the original advocate of the plan of having the functions of the examiners [U. S. Patent Office] confined to examining records and citing similar inventions, leaving the applicant to determine whether or not he would take a patent in the face of the records submitted for his enlightenment, and I still believe that is the surest way of avoiding the abuses now existing. The work of the Patent Office has outgrown the present system.—*Edward S. Renwick.*

.... THERE should be no politics about the Patent Office, not even in the appointment of the commissioner, and then there would probably be a greater degree of fairness. This would also obviate the frequent change of commissioners. More room, more intelligence and less red-tape are also requisite to complete reform —*Edward C. Davidson.*

.... THE complaints that patent attorneys, inventors and others are justly entitled to make, arise mainly from the substitution of green, fresh young men for the men of longer experience.—*Charles J. Gooch.*

.... THE intention of the patent system is all right, if Congress would appropriate enough money to make it efficient. The Patent Office is much more than self-supporting, and inventors feel that some of the surplus should be expended to secure to themselves fair play and more expedition. The abuses complained of are largely due to parsimoniousness on the part of the government, as the salaries of examiners are so small that they seek more profitable fields of usefulness.—*Harrold Serrell.*

.... THE Patent Office needs more room, a larger force and less red-tape and incompetency. Too much time is wasted on unimportant technicalities, and the evil is growing.—*James A. Hovey.*

.... I AM sure the general intention of the Patent Office officials is to be fair and just to honest inventors, but many abuses have crept into the modes of conducting business in the department. The officials doubtless try to secure expert and honest examiners, and, as a rule, they succeed, but some incompetent men get in, and others undoubtedly lack honesty.—*Alfred E. Beach.*

.... THE first thing in a novelty is to make it perfect. When you have made it perfect, and you find it expensive, the next thing is to try and lop off the excresences, and bring it down to within the range of practice.—*W. H. Preece.*

.... ONE of the great desiderata of a system of lighting is constant supply. It is not sufficient to supply the illuminant for a specified number of hours per day; what the householder wishes to have is a means by which he has always at hand a reliable source of light, capable of supplying all his requirements night and day. —*Henry Edmunds.*

ADDRESS BEFORE THE ELECTRIC CLUB.

BY PROFESSOR C. F. BRACKETT.

[New York, December 20, 1888.]

CONDUCTORS—SPECIFIC RESISTANCE—A FORECAST IN ELECTRIC LIGHTING.

THIS is the first time in my life that I ever had the pleasure of facing an Electric Club, although it has been my fortune, good or otherwise, to give instruction in electricity, and I am bound here to confess—a very willing confession—that if I had students under such auspices as I should have had them here, I think I might have succeeded in teaching them something. The Electric Club of New York seem to know how to surround themselves with the physical inducements to study, and I think if students could generally be introduced into such pleasant circumstances they would be considerably more inclined to appreciate their opportunities than they are at present.

The topics to which I would invite your attention are those which present themselves naturally to the working electrician as well as to the student of electricity. Let us consider first a practical matter. In the applications of electricity to our daily wants we make use of those material substances called conductors, and we interpose them in the path where we would like electricity to flow, but where we do not wish it to do so we place substances called non-conductors. It is known to you all that there is no very sharp line of demarcation between these two kinds of bodies. It will suffice in general to say that the common commercial metals act very well as conductors. I desire to draw your attention to two points, and, for the purpose of illustration without a black-board, I will ask you to follow me with your imaginations. Suppose one point A, and another point B. They are at different electrical potentials. If we join the point A with the point B by means of some metallic conductor, we shall find that in a given time, very short, there will be no difference of potential between A and B, and we shall find also, if we use proper appliances, that something has been going on in the wire, or in the region of the wire, which connects those two points. When we say in the wire we are not sure that we are telling the truth; when we say *in the wire, or in the region about* the wire itself, we are sure. If we employ successively copper, gold, or silver wire, we shall find that the equalizing of the electrical conditions of points A and B is in general not accomplished with equal facility. In other words, we find that all bodies are not equally good conductors. Now, copper wire being generally used on account of its excellence as a conductor and its moderate cost, it interests the electrician to know when he has the most efficient variety of copper wire. The matter then which I wish to discuss with you first—and let me say in passing that if I do not make every point clear I invite questions as we go on—is, how is the electrician to know that he is using the very best quality of conductor under any given circumstances. Often times he wants to use the greatest possible power of conduction with the least possible bulk, or with the least possible amount of weight, as, for instance, in the construction of certain pieces of electrical apparatus, such as the dynamo. He will be guided in his constructions very much by his knowledge of the materials, and especially of the conductivity of the materials which he proposes to use. Let us speak for one moment of the specific conductivity of conductors. The word is used precisely as in science we use it, with reference to other properties of matter when we refer them to a standard. It was assumed by the committee of the British Association that *pure* metals should in some way be taken as the standards to which commercial samples should be referred. In the case of copper we must be able to secure it in a state of perfect purity, and to draw it into a wire of perfectly uniform diameter. A definite length and diameter will then fix

the standard. Or we may take a definite mass of copper, as determined by weighing, and fix the length of the conductor to be made from it and assume that nature will fix the diameter. Finally, we may attempt to deduce the diameter of a known length from its weight and specific gravity of copper. All these plans are beset with difficulties. Let us discuss the matter.

If we say that a wire one one-thousandth of an inch in diameter and one foot in length shall have a resistance of 9.718 ohms, we have made a statement equivalent to the one made by the British Association Committee. How can you know that this wire is a foot in length? That is not a very difficult matter. How are you to know that it is a thousandth of an inch in diameter? There comes a difficulty. But the British Association did not attempt to make a wire just one one-thousandth of an inch in diameter. On the contrary, they drew a wire of some size and deduced from the resistance of that wire what would be the resistance of the same metal if its diameter were reduced to one one-thousandth of an inch and its length were made one foot. Now, let us, before we leave this inquire what are the difficulties in the case. We have a wire which in general terms we will say is one-sixteenth of an inch—Matthiessen's. We want to know in tens of thousandths of an inch exactly how much it measures, for the least variation in the diameter of it of course implies a much larger variation in the area, and that implies a very large variation in the conductivity—so the slightest error made in the measurement of its diameter enters very largely into the final result. It is true that we have screw gauges and vernier calipers at our command; but yet we can hardly by any of the devices determine the real diameter to within at least fourteen or fifteen-hundred-thousandths of an inch, and that makes a vast difference in the conductivity of a wire, especially in the case of small wires. Let us take the other plan, specifying that the samples being a foot in length shall weigh so many grammes or grains; again we will have one of the British Association methods on the basis that a cubic foot of copper weighs 555 pounds—that it is nearly 555 pounds. If a cubic foot weighs about that and not exactly that, there is a doubt about it which will seriously affect the result. The difficulty is at once seen when stated. They also specified that the specific gravity is so and so, or that it shall be so and so. Now, if we take the Smithsonian tables collected under the direction of Professor Henry, we shall find that the specimens of copper there reported, as respects their specific gravity, vary all the way from about 8.95 down to 8.40, a variation enough to make a very great percentage of difference in the conductivity of copper. Now, to what are these discrepancies due? The question what is the specific gravity of a metal is the one which can only be determined in a given case by taking that particular piece of metal which is to be employed and determining its specific gravity. Then let us look at the process of wire-drawing. Suppose we draw the wire through the draw-plate. What is the operation that goes on? Is the wire simply stretched and made longer and smaller? Is the wire compressed as it passes through? The experience of the wire drawer will perhaps come to our aid and tell us something about it. I had occasion, some time ago, to apply to one of the most expert drawers in the great works at Trenton—Roebling's—using a jeweled draw-plate through which the wire was to be drawn, and having a finished sample of wire to be drawn through it. The workman at once said: "That cannot be drawn through it." Said I, "Why?" He said; "The wire is too small." Now there may be, and there probably are, gentlemen present who will see at once the reason of that statement. It is found that if we wish to reduce a wire from one size to another, we must reduce it by a considerable amount or we cannot draw it through a plate at all. The wire is a little large for the hole. Instead of there being pushed up a mass of the metal in front of the hole, the metal is compressed and becomes very hard, and is wedged into the plate, and breaks. If, on the contrary, the reduction in size is so great that this does not happen, it is found that it can be drawn through with moderate tractile force, and that it has a more uniform structure. Let us then consider what happens when we attempt to pull the wire through the plate; what happens to the wire after it is pulled through. Here experiment comes to our aid. Wertheim, in some experiments of his, found that when any substance is stretched, the entire bulk of that substance is enlarged. An instructive laboratory experiment is performed by means of a long mass of rubber in the form of a parallelopiped, whose length can be measured, whose side and thickness can be measured. When we stretch it we find that if it be calipered at uniform distances, and the volume under those circumstances be computed, it is greatly increased. One would naturally think that it would be diminished in section as much as it is elongated, so that its volume would remain constant; but it is not so. If you take a piece of rubber as long as your finger, find its specific gravity by weighing it in the usual way, put this in a stretching apparatus, and you will find its specific gravity has been diminished, and the bulk increased. The same thing is true of the copper. The wire after being compressed in its passage through the draw-plate is expanded by the traction required to draw it through; and, besides this, the structure of the metal is greatly influenced by the constant change in the relation of the surface and the central parts. The former is constantly held back, and furnishes the material from which the increased length is derived; it is thereby heated and so annealed while the interior remains comparatively hard and brittle, and so is liable to break and leave the interior of the finished wire unsound. Now, the question which arises here immediately is, how much it will be expanded, and, therefore, what will be its specific gravity after it is through? You must see that it will depend on how much it is reduced in size, and what is the condition as regards annealing before it is drawn through and afterwards, so that when you state that wire is hard drawn and has such and such a specific gravity, you are stating two things not necessarily compatible. If you have a certain mass of matter having a certain length between points A and B, if the mass be highly compressed so as to occupy only a small space, one might suppose that the particles are nearer together, and therefore they could less readily execute the motion involved in the transfer of electricity from one point to another. One might say on the other hand, if a wire were annealed, rendered larger, there would be greater freedom of motion, and so, a greater conducting power. Those are both theoretical matters, but there are experiments tending to prove the truth of either position. It is found that the conductivity is improved by annealing. But what do you mean by annealing? Do you mean the wire shall go into the oven and be heated to redness and kept so a certain length of time, and then be allowed to cool spontaneously?

A short time ago a specimen of wire came to my notice to be measured for conductivity. It was found to be very low. On examining its physical properties it was found that if it was flexed sharply on itself any attempt to straighten it broke it short off. The question was given to me for investigation, to find to what this was due. The conductivity being too low, and the physical state of it being such as we would call brittle, it was supposed, of course, that it might contain arsenic, or that it might contain sulphur, and very rigid tests were made for these substances, but neither of them was present. Tests were made for oxide of copper, which in the annealing process might have been absorbed into the interior. On making a careful test for sub-oxide of copper, there was found to be no more present in it than in other wires which were tough and whose percentage of conductivity was over a hundred. Then the question arose, to what is this due? Accordingly a sample of the tough wire that could be

flexed in any way you pleased, that had a percentage of conductivity of over a hundred, was taken and heated for a little time in the presence of hydrogen gas—heated to redness. It was found on cooling that it would not bear a single sharp flexure. On trying to make it bend as an ordinary wire, it would break half way off. It appears then, that by the pressure of hydrogen and the existence of a high temperature, a new molecular condition was impressed upon it. This investigation was made by Dr. McCay.

Along the same line I might note another experience which was accidentally come upon. A large amount of iron wire was made for telegraphic purposes. It was shipped to its destination, and on being unloaded roughly, as usual, the wire was found to break into pieces as if it had been a rod of glass. On being carried back to the factory and nothing else done to it except to draw it through the draw-plate, it was thoroughly restored, showing that the whole matter is due simply to molecular change—that it was restored by mechanical treatment.

Now this short discussion will settle the point which I have brought up—what did the British Association mean when they said a wire so long having such a diameter shall be taken as a standard? They mean absolutely nothing, for they have not specified how it is to be drawn through the plate; they have not specified how it is to be annealed nor how many times it is to be annealed, nor given any specific mechanical detail about it.

Now, let us consider another phase of wire drawing for a moment. Suppose we had a standard. Suppose these questions were all settled, first as to the purity of the material, second as to the method in which it should be drawn, and how it should be annealed, what kind of draw-plates shall you draw it through? If you are to use jewels, such as a topaz or something of that sort, for every final drawing of the wire, that course would seriously embarrass every concern in the community. You can draw only a very limited amount of wire through the plate, and then it is worn out. We must, therefore, fall back on steel, the only available thing, and see how that will work.

I will narrate a little experience. Having wires sent to me by various firms to study and report, I have invariably found that when a lot of wire which was continuous, without any joints, was examined, both ends of the wire were large and the middle small. I think that is probably the experience of all—that the middle is reduced. What, therefore, is the diameter of the wire?—how shall we get it? It is larger in one direction than in that at right angles to it, and gives you neither a circle, an ellipse, nor any other regular geometrical figure. Well, of course, those who wish to save trouble say, let us weigh it. Suppose we determine to measure it without weighing it. Of course we will have to run our calipers around the wire and we have to discuss the figures we shall get from that, and having determined the area of the cross-section and the length of the wire we can refer it to the standard of the British Association, and if that were accurate our work would be done.

But we find that it is not safe to assume that these wires will be uniformly smaller in the middle, and we have, therefore, to look into the facts. When we begin drawing the wire through the plate the first effect of it is to heat the plate. Before the heat is conducted to the outer parts of the plate the interior parts get warm, and they have no other way of expanding except inwards, thus contracting the hole. The consequence will be that, for a short time, the wire will pass through the hole at nearly its full diameter; but from the beginning the heat evolved in consequence of friction will cause the diameter of the hole to decrease until at length a point will be reached when the conduction and radiation from the plate will remove the heat as rapidly as it is produced. Meanwhile the rough surface of the wire will cut away the plate and thereby increase the diameter. There will thus be two stages in the alteration of the draw-plate; during the first the diameter will on the whole be diminishing, and during the second it will be increasing. Accordingly the wire will be smaller at some point between the extremities than at either of them.

The wire will then be of varying diameter, and one who would ascertain it for the purpose of finding the conductivity of the sample, will have to make a series of measurements at various points along the length as well as in various azimuths about its axis, very much as the surveyor treats an irregular piece of land. Suppose he wishes to avoid all this labor, and says, I will weigh it. There is difficulty if you do weigh it—how will you deduce the bulk from the weight without knowing the specific gravity? If you turn to tables you will find 20 or 30 different specific gravities assigned to copper wire. If you say, I will determine the specific gravity myself, then the expense will be too great if any considerable number of samples are to be tested.

Now, having stated some of the difficulties with reference to the matter, let us inquire what ought to be done. It is known, I suppose, to most of the gentlemen present, that the British Association Committee still have this matter in charge, and have undertaken, at their recent meeting at Bath, to have the whole question re-examined, and it is to be hoped that something will be elicited which will give us a standard for the conductivity of copper wire, so that we shall know whether we are getting one thing or another. It may surprise some of you to be told that we very frequently have from the manufacturers in this country samples which will run as high as 103 or 104 per cent. of conductivity. In other words, they are three or four per cent. better than they can be, taking the British Association as a standard. Now the matters which I have already brought forward, of course, enter into the reasons. At the outset it was assumed that the pure metals were to be accepted as standards. That is not the whole matter. It does not by any means follow that when you have assured the purity of a metal you have secured the highest conductivity. You have also to ask what is the length, what is the diameter, what were the methods of its preparation, and, unless they are all defined, there can be no certainty that you are getting within two or three, or three or four, per cent. of the proper conductivity.

Now some one says, what is the use of this after all? There are conditions in the art of the practical electrician in which he must say beforehand, precisely how many feet of wire he can employ, precisely how much space they must build up in order that he may have symmetry, equality and proper conducting power. I think any one who has attempted to wind the coils of the dynamo machine so as to secure a definite number of ampere turns will agree that a variation of two or three per cent. in the conductivity of his copper wire makes the difference between success and failure.

Now, having said so much with reference to a practical problem that interests everybody, let us turn our attention a few minutes to matters that are more speculative. It is not only true that it becomes important for us to have conductors which shall convey from one point to another the disturbances which we call electrical; it is also true that in the construction of machinery at the present time, we are to take into account the air spaces between those conductors; we have to take into account the intermediate thing which separates one conductor from another, and inquire what goes on in that space. And it will not astonish many present when I put it this way. Theoretical electricians who are studying the question very hard are getting to look at it in this way. We are not more concerned with what goes on *in* the conductor than we are with what goes on *about* the conductor. In other words, the principal transaction in the electrical transmission of energy from one place to another goes on not in the substance of the wire but in the space which surrounds the wire. We ought to get into the spirit of these electricians,

and look at the ether through which we move as the most important of all materials with which we have to deal. Think now of the air and of everything utterly vanished, a perfect vacuum, and then cut out a solid "chunk" of the vacuum and see how it behaves. We shall find, probably, in the light of recent investigations that this is the most important thing we have to deal with, that the whole action which we call transmitting goes on in that, and that the conducting wire is only a hole bored through it. It is simply so many masses of matter called molecules that are swinging around and making an easier path, and this determines the direction through which the electrical disturbance shall be manifested. There are certain transactions which we may look at. For instance, a wire can act inductively through a vacuum just as well as through the air. No one is, I think, able to imagine to himself, under any circumstances, whatever he may say, action across a space where nothing exists. Faraday in grappling with this same subject said, in substance, that it was unthinkable. Newton gave his great deliverance also along the same line.

If, then, action at a distance must be ruled out, there is something between the conductors themselves which we have to take into account. Now the experiments and researches to which your attention has been called in the electrical literature of the day, which have been going on for several years past—in fact they date back many years—have cast a great deal of light on this subject, and while it may not seem immediately practical, it may be that some word which will be dropped in what I shall say, or in the discussion, will set some one to thinking.

Now, in order to proceed step by step, let me propound the ultimate question which I suppose may interest a large number—how to produce an electric light in the very cheapest possible way? That is a practical question. Now I am going to try to see if we can get to it in a philosophical way (without realizing it), but upon the paths if possible by which it will probably be ultimately reached. Faraday, in one of his brilliant papers in which he set forth the principles of "the new electrical machine"—the starting point of modern dynamo appliances—made use of words like these :—

"I have rather, however, been desirous of discovering new facts and new relations dependent on magneto-electric induction than of exalting the force of those already obtained ; being assured that the latter would find their full development hereafter."

Now, in the spirit of what Faraday said, let us look at this subject. Nothing will be practical that I shall say. I shall not show you how to make that machine, but I propose to scale past the lines along which it may come, and in doing so I will be very brief. First, what is light? This solid ether which we have spoken of, which is a necessity in the phenomena of light and which Fresnel assumed has an existence, in order to tie together the inevitable deductions from his equations, must be thought of as something evidently more solid than the solidest things we think we know about. When we get light we get it by setting up vibrations in the ether, and all I say about these vibrations is this : They are periodic, they are uniform, they are transverse to the line of progress, so that if the beam of light were going directly from me to you, the motion is athwart the beam, so that a particle can be thought of as moving this way and another around that way (illustrating with a pencil), and so in every possible direction at right angles to the line from me to you. Now the question is : Is there anything connected with electrical science by which we shall be able directly, ultimately, to evoke that method of movement? In 1832, Professor Henry showed that when a Leyden jar is discharged the spark which we have been perhaps accustomed to think of simply as a passage of electrical fluid from one side to another, on the contrary, was a series of transmissions back and forth from the outside to the inside. This he showed to his own satisfaction and embodied his conclusions in a paper which is, of course, extant at the present time. Later, Fedderson took up the question and studied it with care, and showed how to compute the length of time involved in any one of the elementary discharges passing back and forth. In 1855, Sir William Thomson showed how to compute from the induction of the wire and the capacity of the jar, the time interval involved in one of those oscillations. Here is a trough of water on one end of a pipe and another on the other end. The one trough being empty, water runs through and accumulates on one side and by its impetus it will pile up a little higher and we will have a series of oscillations, and finally it will come to rest. That is exactly what happens when a Leyden jar is discharged by a series of oscillations. Now we can put such a conductor between the two troughs that there shall be only a steady flow from one side to the other. We shall find that there will be no oscillation in that case back and forth. If we put there a very small wire or a wire having large inductive capacity, I can get a steady discharge in the case of the Leyden jar. Any way we can control it and show what is the length of time involved without any difficulty.

Now, to make a long story short, it may be stated that Hertz has for some time been studying the oscillatory discharge, and his more recent labors have thrown a great deal of light upon them. I will not allude to all of his experiments in order, but only mention such of them as best suit my purpose. In order to understand one of them, consider a simple experiment in acoustics. A long rod of wood or metal is held firmly between the thumb and finger at its middle point. If it be pulled gently with the other hand which has been covered with a little powdered rosin, the rod breaks out into a clear musical note, as clear as that of a violin. The effect of the friction has been to produce a series of condensations and rarefactions which travel along the rod, thus showing that it is in vibration. Hertz arranges a long wire with a metallic conductor of considerable capacity on each end. The wire is cut apart at the middle point, and the ends so made are brought in contact with the discharge rods of the induction coil, which are furnished with small balls between which the spark can pass. A small rectangle of wire with one side cut open at the middle, and the two ends armed with small adjustable balls, serves to show what is going on in the long wire system just described. This it can do by the presence or absence of a spark at the opening between the balls. When the induction coil is set in operation, the electrical oscillations in the primary system are shown by the induced sparks in the rectangular system. If the periods of oscillation in the two systems be made as nearly as possible the same, the brilliancy of the spark in the secondary is much increased—just what should happen on the principle of resonance. They are then waves set up in the conductor, and their frequency can be calculated. Now, according to the electro-magnetic theory of light proposed by Clerk-Maxwell, the disturbance which constitutes electrical induction should travel with the velocity of light, or about 185,000 miles per second. It is then easy to find the length of the oscillations with any given number of alternate discharges, such as are produced in the experiments of Hertz, for we have only to divide this distance, 185,000, by the number, which gives the length of one, provided we may assume that the disturbance is propagated in the wire with the same velocity as a disturbance is propagated in the air. Hertz, however, found that this is not the case. His experiment was carried out somewhat in this way : Two large metallic plates were furnished with wires terminating in knobs, and so placed as to be in the same vertical plane, with the knobs near each other, so that a spark could pass when the two were connected with the induction coil terminals. Behind one of the plates was placed a third, so as to be parallel to, and near it, and from this a wire was led to a

considerable distance away and put to earth. Any electrical disturbance in the plates joined with the induction coil would, of course, induce a corresponding one in the third plate, and so in the wire connected with it. Suppose we want to find out whether there is anything going on analogous to the transmission of waves in sound, we would go alongside of the wire and see if there is a place where there is a neutral segment, and further, if we find that repeated again and again, in other words, we ascertain if there is a series of waves—what kind of a test shall we employ for this purpose?

All we have to do is to make a little induction coil, put a knob on each end of the coil and bring them near each other, and see whether a spark passes. Suppose the wire be stretched here (illustrating with an imaginary wire), we look carefully and find a spark passes. Then passing along the spark grows dim, now it grows a little stronger; we find it here very strong; we pass right on and find that when we go over the same distance again it increases and diminishes. If we do this we find the distance between the nodal points. In other words, we find the result absolutely, the result we were looking for, by the inductive effects in the wire.

Now I will not weary you with that part of the thing, for there are a great number of experiments which can be tried. We find in this instance that when the wire transmits these electrical disturbances, there is in the ether, or in the air, close by its side, another disturbance transmitted; that is to say, we have the one taking effect along the wire and the other taking effect along the ether. Now do they travel with the same or with different velocities? It is found that the rate of transmission in the wire is different from the rate of the transmission in the ether. Hertz finds that if he employs iron wire, copper wire or zinc wire, or wire of any other metal, it makes not the slightest difference in the position of the nodal points. In other words the length of the wave remains unchanged, and it makes not the slightest difference whether the diameter be small or great.

Now, let us look at what light is for a moment, and then we will see how we should produce it. I have already stated that light is a motion transverse to the line of progress of the wave. Now I am going to ask you to follow me through a little severe thinking.

Faraday, in the height of his enthusiasm as an experimenter, endeavored to connect gravitation directly with electricity. He made coils of wire and threw them out of an upper story window and let them fall down to the earth in order to see if he could get any electric disturbance. Faraday had already investigated an action closely analogous to that of gravitation, for he more fully than any one else explained or rather described the character of the region about a wire which is conveying a current of electricity. Here is a wire and a current. Suppose a current is passing directly down through it. We need not discuss now what a current is, but will take it for granted that the wire joins the brushes of a dynamo machine. Now bore a hole in a glass plate, push the wire up through the plate, send the current down through the wire, sprinkling some ordinary magnetic sand, such as was once used on the writing desk, all about the wire. When the current passes we shall find on gently tapping the plate that there are arranged certain well marked lines around the wire in more or less perfect circles. Now we have mapped out what are called circular lines of force, and the region is called a field of force. Now let us see what properties this has. If in such a region we bring a pole of a magnet, and this be perfectly free to traverse around it, we shall have this magnetic pole revolving along these lines of force, and when it has gone around the circle a certain amount of work will have been done. Now suppose, in order to make clear, we split the conductor down the axis here (showing with a pencil), this way here, and so on, turning through a certain number of degrees each time and in every one of those splits we insert a card then we shall have a fan wheel, every one of these cards will represent an equi-potential surface. This floor on which I stand, supposing it to be level, is such a surface as respects gravitation. It is an equi-potential surface on which we can place a locomotive and set it going, and no work would be done in consequence of climbing up here or going down there. The floor above would also be an equi-potential surface, but the man who attempts to go up there will, of course, do work in going from one place to another. Now all of the little equi-potential surfaces about our wire are just exactly to each other as these floors are to each other. If we come from one card up to the next, we have to do some work, and the work is estimated in the same way as the work would be in getting from one of these floors to the other.

Now one case differs from the other only in the fact that the thing which produces it—notice carefully how I put this—it differs only in the fact that the thing which produces it in the one case is the current going through the wire, whereas in the other you have a great mass of rocks and material making up the mass of the earth. If we go from one of these earth planes to another we do exactly the same as we would in passing from one of these planes about the wire to another, only the lines which join these planes are said to be plumb.

If a current be passing in any given direction, say thus, it is accompanied by its magnetic field, consisting of circular lines of force and its radial planes, as we have seen; now, the theory of Maxwell requires that the effects of any variation of the current, and so of the magnetic field, shall be propagated outward with the velocity of light, the direction of the propagation being at right angles to both the current and the lines of magnetic force so-called. Now, we are very near the end of this discussion, and have reached a part which I desire that you all catch hold of. Suppose, instead of having a continuous current passing down the wire, and having this magnetic pole revolve around it like this, we put in an alternating current. Then these circles are developed around the wire; but these circles are, in their tendency, to carry the magnetic pole around constantly reversed. When you have the current go up you have one movement, and when it goes down you have the reverse. Now, there is not simply one of these lines wound about the wire, but another and another and another, out as far as you please to go. The question now is how may we soonest pass from a position on one of those lines to one on another. We do it by a motion which is exactly at right angles to them as well as to the direction of the producing currents, and an ether particle will vibrate in the same period as the current, and that vibration is light.

Now, I will go back again. Hertz found in a large hall where he carried on his experiments, that there were certain interference phenomena; for instance, the length and the strength of the induced spark was different from what it ought to be. He kept in mind that the adjoining side of the hall presented a large reflecting surface. If sound had been thrown on that it would have been reflected back. If a wave of sound struck on the adjoining wall it might be thrown off and give an interference, as two sounds not differing in pitch may give you absolute silence. He found that when he moved his apparatus from one position to another with respect to the wall, he could either cause the sparks to appear or disappear according to the relative distance at which he placed them. He thus found that his waves were about nine meters long. He calculates the time occupied in one oscillation, from the wave length and the known velocity of light, and finds that it agrees fairly well with the value calculated from the capacity and inductive capacity of the circuit employed. Now, how long are these light waves by means of which we can see? Divide your millimeter into ten million equal parts, take those as your units, write down .588, and you have the

wave length of ordinary yellow light. It is, therefore, inconceivably shorter than any distance that we are accustomed to measure, except by indirect trigonometrical processes. Now that is something like the wave length we want to see with, but the wave you get by Hertz's method is much longer than I can reach. When we can produce alternations of current sufficiently rapid, we shall have the light we want without the production of an immense amount of heat which we do not want. Now suppose we had achieved that. A wire which is now a conductor and conveys a large amount of energy from one point to another would then convey just the form of energy we want, light would beam out from the conductor and you might handle it without any heat being perceptible. It would simply burst out with light and be a luminous thread running through the air. That is what electric lighting has to reach, or otherwise it will not be perfect. It is altogether likely that no conductors with which we are at present acquainted will suffice to transmit such alternations of current as we need. Langley's experiments on the moon show it sends wave lengths greater than those which come from ice, and you have not only those, but you have all grades of vibrations up to those which are away beyond all possible means of detection except by the most refined photographic processes, and in order to get what we want—these miserable few vibrations suited to vision—we have to produce those altogether. As Professor Lodge has said, it is as if a man who wished to have less than one single octave must blow the whole organ at one time. That is what we do as a matter of fact. I now suggest one or two things that look hopeful. I am not afraid of giving this away, because I do not believe any of you will get up to-morrow and accomplish it, and I do not pretend that I see my way clear, though I tell you frankly I am going to experiment. Let us see what we can do. We can take an electric current and make it alternate—we can do that perfectly. We can make magnetic waves go back and forth and make the current alternate. Now what we may try to do is to take a beam of light which has a vibration already in parallel planes and harness that to a wire, so that it will make a current vibrate and also make the magnetic field about the wire vibrate. In other words, if you cannot do the sum, take the answer and work it backwards. That is what I propose to do, and I will hint to you exactly how I propose to do it. It cannot be done with the ordinary materials employed for conductors if it has to heat the wire. The heat in the wire is most likely due to nothing else than a series of closed electric circuits in which the electric motion is around the molecular parts. We must get something that is not a conductor in the ordinary sense. I remind you that the amount of energy expended in the movement in the high vacuum tube, in the ordinary tube where you have the most beautiful illuminations is, as a matter of fact, very small, since, when it is properly managed, the amount of heat generated in it is very small. I point out to you next that there is one substance in which we have the properties of both the conductor and the non-conductor present, and there are some very hopeful indications in that. A selenium cell, in which the selenium is so thin as to be semi-transparent when it is joined up and a battery current is put through it, is found to have its resistance diminished immediately a flash of light falls on it. The question is, does its resistance diminish immediately, or is a force set up which conspires with the electromotive force? I do not know which it is, but something may be advanced in favor of either view. Let us see how our problem works backwards. Suppose we make a polarizing apparatus by which we can polarize a long web of light. We could employ several glass plates. Let sunlight strike on this bundle at the proper angle and the light that is reflected from it is polarized. It will consist of vibrations all sorted out in parallel planes by themselves, so that they will not be fighting at cross purposes. Now let this long polarized web of light be passed through a narrow slit so as to pass directly upon, or near, the conductor in which we wish to set up an alternating electric current. If the proper conductor can be found, it should have the current set up in it and this should produce a magnetic field about it. If we put an alternating current through the conductor we shall get a series of alternating magnetic circular lines of force and light waves. Therefore, if we take the latter right by the horns, so to speak, and apply them as an electromotive force, we ought to be able to evoke the electrical current and the magnetic field at the same time. In other words, those three factors being in existence, any two of them ought to be evoked by simply giving the one. That is what ought to be brought about; whether it will be brought about with conductors or with non-conductors, I do not presume to say; but it will have to be done perhaps indirectly. The experiments of Hertz show that electrical actions can go on exactly like acoustic actions. The theory of Maxwell—and the experiments of Hertz confirm it—is that the actual wave of electro-magnetic induction is at right angles in the lines of magnetic force, and to the electrical disturbance by which they are set up. Those waves differ from light by which we see, only in their lengths. They need to be shortened. What we want is an alternating current or discharge of some sort or other, which shall enable us to produce the alternations with such frequency that the so-called conductors will break out and shine directly. If we see no way of doing it at the present time, let us try to work the problem backwards by taking light from the sun and polarizing it and applying that to the conductor, and so endeavor to set up in the conductor alternating disturbances which correspond with it in frequency, so as to note their effect, and see, if possible, precisely what we have to do. A dynamometer ought to be constructed which would be capable of measuring the effect. But with the ordinary opaque conductor such frequency means confusion among the molecules which brings about a difficulty. That is what we must get rid of.

You have been remarkably patient and I beg you will accept my thanks for the way in which you have endured what I have said, and for the courteous invitation you have given me to come here and talk. It frequently happens that one who can talk longest on a given subject knows the least about it. But I chose this subject with "set purpose and malice aforethought," not that I hoped to instruct you, but thinking that some one among you might catch an idea from my remarks and see that there were lines of experimentation which have not yet been developed, some of which I have briefly sketched. It seems a shame that we cannot have such vehicles as we choose—that we cannot get light without heat—that we cannot get the result we aim at directly without the accompaniment of so much useless waste. You are burning up tons of coal for driving machines to no purpose whatever. Where is there an end to be reached? In the light of the doctrine of the correlation of forces and conservation of energy we should be able to reach the desired result with all simplicity.

.... By affording inventors opportunities for posting themselves on the records of inventions and giving patents to all applicants therefor, many of the graver abuses of our system would be done away with, and the real inventor have a better chance of maintaining his rights.—*Alfred E. Beach.*

.... We always find in every new system that if we attempt at once to attain completion and perfection we are sure to introduce complication and expense.—*W. H. Preece.*

.... A secondary battery has one remarkable point connected with it that has not received the attention it deserves. It is this—that a battery is a kind of automatic governor; that the internal resistance of a battery that controls the external work done by the battery varies with the current that goes through it, so that if you discharge a battery with a small current you get one internal resistance. If you discharge it with a larger current you get very much less internal resistance.—*W. H. Preece.*

STATISTICS OF PATENTS ON ELECTRICAL AND RELATED INVENTIONS ISSUED FROM THE U. S. PATENT OFFICE IN 1888.

COMPILED BY THOS. D. LOCKWOOD.

THE number of patents issued during 1888 upon electrical and allied subjects, including phonographs and mechanical telephones, is 1,503. These may be classified as follows :—

1. Electric signaling, 185 patents, comprising:—

Annunciators, alarms (simple) and bells	70
Burglar alarms	11
Clocks, etc	18
Fire, and heat alarms and district and police telegraphs	46
Railroad signals and train telegraphs	40

2. Telegraphs—proper—64 patents. These I divide into :—

Autographic and automatic telegraphs	6
Morse telegraph instruments, etc	24
Multiple telegraphs	9
Printing telegraphs	18
Novel systems of telegraphy	7

3. Heavy current applications—365 patents—comprising the following sub-divisions :—

Arc lamps	27
Electrical distribution	54
Incandescent lamps	36
Lamp fixtures	18
Lighting apparatus	39
Railways and motors	137
Transmission of power, telepherage and stationary motors	54

4. Development, control and measurement of electricity —347 patents. Sub-divisions :—

Primary batteries	84
Secondary batteries	59
Dynamo and magneto electric machines	102
Galvanometers, measuring apparatus, etc	60
Dynamo regulators and governors	42

5. Conductors—insulation, etc.—76 patents. Sub-divisions:—

Cables	8
Insulated wires	17
Pole line insulators	5
Insulating materials	5
Line wires	2
Supports, cable hangers, etc	13
Underground conduits, etc	26

6. Miscellaneous and general appliances, numbering 264 patents. These comprise the following :—

Miscellaneous applications	187
Couplings, connectors and binding screws	5
Circuit breakers, closers and changers	26
Electro-magnets	9
Electro metallurgy	13
Gas lighting	24

7. Inventions in or concerning telephony—202—comprising :—

Battery or other transmitting telephones	23
Magneto or other receiving telephones	7
Guards against destructively strong currents	16
Switch-boards	5
Telephone exchange system and circuit arrangements	18
Telephonic repeaters and relays	1
Miscellaneous telephone appliances	52
Individual signals	3
Other telephone signals	8
Telephonic miscellaneous utilizations	24
Mechanical telephones and phonographs	41
Remedies for electrical disturbances	4

The only point worth notice in the above, is the number of patents issued on inventions in railways and motors, viz., 137, which brings the total of the heavy current class up to 365, one for every day, save one, of the year.

The issues of the several months were respectively:—

January	79
February	96
March	108
April	134
May	198
June	116
July	143
August	108
September	106
October	125
November	162
December	138—1,503

Showing an average of 125¼ per month, and an average of 28$\frac{9}{10}$ per week.

Considering the inventors alphabetically, we find that they count up as follows:—A, 23; B, 150; C, 85; D, 69; E, 73; F, 56; G, 57; H, 127; I, 5; J, 28; K, 46; L, 50; M, 101; N, 18; O, 18; P, 63; Q, 0; R, 73: S, 186; T, 87; U, 2; V, 40; W, 130; X, 0; Y, 5; Z, 8.

Examining these names, we find that *S* crowns the list, not as usual by the efforts of the Smith family, but by the display of energy all along the line, and chiefly in the persons of O. B. Shallenberger and C. E. Scribner, the former name appearing 26 and the latter 22 times.

B comes next with 150, W third with 130, H has the fourth and M the fifth place. Q and X alone are without representation.

The letter I comes out in 1888 with unusual vigor, and reaches the figure 5; while J, by reason of no less than 9 Johnsons, reaches 28; Johnson having fairly beaten Jones.

N, holds its present place by the exertions of a *Newman;* who took out one-third of the entire number, while Tesla and Zalinski also do their best for their respective initials.

The entire number of patents of all classes issued (less, however, a few withdrawn) is 19,585.

The electrical patents amount, therefore, to 7.67 per cent. of the whole.

POINTERS.

.... "COINERS" used to stand for *counterfeiters*. This term might be well employed in the same sense to describe many of the utterers of new words. "Electromotive" for an electric locomotive—a specious but particularly base counterfeit—is one of the newest atrocities.—*T. D. Lockwood.*

.... IT ought to be more generally known that the "ohmic resistance" of an electric conductor, referred to by Sir William Thomson in his inaugural address before the Electrical Engineers of London, increases directly in proportion to its feetic length, and inversely in the ratio of its poundic weight.—*George B. Prescott, Jr.*

.... BRAKES that save the power instead of wasting it are of purely English extraction, but their conception has recently come across the Atlantic with such a strong Yankee accent, that it might pass for having been born and bred in the States.—*Professor Ayrton.*

.... THE practicability of the transmission of energy by currents is assured, and the economy of doing this is a mere matter of calculation. It is a question of the relative cost of the transmission of energy by wire.—*W. H. Preece.*

.... HAVING now become fairly satisfied with the performance of one system of distribution, we naturally look forward to being able to distribute on an alternative plan at some future date.—*Professor George Forbes.*

.... THE engineer feels that steam and electricity in his hands have done more to economize labor, to cheapen life, to increase wealth, to promote international friendship, to alleviate suffering, to ward off war, to encourage peace, than all the legislation and all the verbosity of the politician.—*W. H. Preece.*

.... IT seems but a very short time since the question of distribution was being discussed and seemed quite hopeless, and I think all of us will feel a great relief when the time arrives that a system of distribution combined with storage batteries, gives us a more efficient and a more economical system of distribution than that which is alone at our disposal at present.—*Professor George Forbes.*

.... EVERYONE should know his Morse alphabet, and people should learn how to write. Nine-tenths of the telegraphic errors made are due to the execrable caligraphy of the present day.—*W. H. Preece.*

HERTZ'S RESEARCHES ON ELECTRICAL OSCILLATIONS.[1]

BY G. W. DE TUNZELMANN, B. SC.

H. Hertz has been engaged for some time past in a series of researches on electrical oscillations, which have led to results of very exceptional interest, as was pointed out by Professor Fitzgerald in his inaugural address to section A of the British Association last week; and as these results throw considerable light on the nature of electrical action, it will be of interest to readers of *The Electrician* to have a connected account of the investigations, to which I therefore propose to devote a short series of papers.

In Hertz's first paper on the subject, viz., "On Very Rapid Electrical Oscillations" (Wied. *Ann.*, vol. xxxi., page 421, 1887), he refers to a paper by Colley, "On some New Methods for Observing Electrical Oscillations, with Applications" (*ibid.*, vol. xxvi., page 432), who calls attention to the fact that Sir William Thomson in 1853 first showed the possibility of producing electrical oscillations by the discharge of a charged conductor, and gives references to all the investigations in the same direction which were known to him.

For the benefit of readers who may wish to pursue the subject further the list is reproduced below.

Sir W. Thomson, "Mathematical and Physical Papers," vol. i., page 540.

Feddersen, Poggendorff's *Annalen*, vol. ciii., page 69, 1858; vol. cviii., page 497, 1859; vol. cxii., page 452, 1861; vol. cxiii., page 437, 1861; vol. cxv., page 336, 1862; vol. cxvi., page 132, 1862.

Kirchhoff, "Gesammelte Abhandlungen," page 168, containing remarks on, and corrections of some of Feddersen's results.

Von Helmholtz, "Gesammelte Abhandlungen." vol. i, page 531.

Von Oettingen, Poggendorff's *Annalen*, vol. cxv., page 115, 1862, and Jubelband, page 269, 1874.

Bernstein, Poggendorff's *Annalen*, vol. xiii., page 142, 1828.

Schiller, Poggendorff's *Annalen*, vol. clii., page 535, 1872.

L. Lorenz, Wiedemann's *Annalen*, vol. vii., page 161, 1879.

Mouton, Thèse, Paris, 1876. *Journal des Physique*, vol. vi., pages 5 and 46, 1876.

Kolacek, Beiblätter zu Wiedemann's *Annalen*, vol. vii., p. 541, 1883 (abstract of a paper published in the reports of the Bohemian Scientific Society in 1882).

Olearsky, Verhandlungen der Academie von Krakau, vol. vii., p. 141, 1882.

Oberbeck, Wiedemann's *Annalen*, vol. xvii., pp. 816 and 1,040, 1882; vol. xix., pp. 213 and 265, 1883.

Bichat et Blondlot, *Comptes Rendus*, vol. xciv., p. 1,590, 1882.

According to these investigations, the electrical oscillations produced in an open circuit by means of an induction coil are measured by ten thousandths of a second, while in the case of the oscillatory discharge of a Leyden jar they are about a hundred times as rapid, as was shown by Feddersen.

According to theory, still more rapid oscillations should be possible in an open circuit of wire of good conducting material, provided its ends are not connected with conductors of any considerable capacity; but it is not possible to determine from theory whether measurable oscillations are actually produced. Some observations of Hertz's led him to believe that under certain circumstances oscillations of this kind were produced, and his researches show that this is so, and that the oscillations are about a hundred times as rapid as those observed by Feddersen; so that their periods are measured by hundred millionths of a second, and, therefore, they occupy a position intermediate between acoustic and luminous vibrations.

Preliminary experiments.—It is known that if in the secondary circuit of an induction coil there be inserted, in addition to the ordinary air space, across which sparks pass, a Riess spark micrometer, with its poles joined by a long wire, the discharge will pass across the air space of the micrometer in preference to following the path of least resistance through the wire, provided this air space does not exceed a certain limit, and it is upon this principle that lightning protectors for telegraph lines are constructed. It might be expected that the sparks could be made to disappear by diminishing the length and resistance of the connecting wire; but Hertz finds that though the length of the sparks can be diminished in this way, it is almost impossible to get rid of them entirely, and they can still be observed when the balls of the micrometer are connected by a thick copper wire only a few centimeters in length.

This shows that there must be variations in the potential measurable in hundredths of a volt in a portion of the circuit only a few centimeters in length, and it also gives an indirect proof of the enormous rapidity of the discharge, for the difference of potential between the micrometer knobs can only be due to self-induction in the connecting wire. Now the time occupied by variations in the potential of one of the knobs must be of the same order as that in which these variations can be transmitted through a short length of a good conductor to the second knob. The resistance of the wire connecting the knobs is found to be without sensible effect on the results.

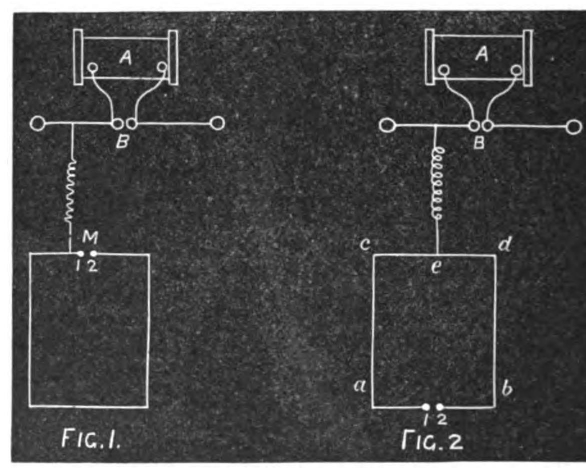


FIG. 1. FIG. 2.

In figure 1, A is an induction coil and B a discharger. The wire connecting the knobs 1 and 2 of the spark micrometer M, consists of a rectangle, half a meter in length, of copper wire 2 millimeters in diameter. This rectangle is connected with the secondary circuit of the coil in the manner shown in the diagram, and when the coil is in action sparks, sometimes several millimeters in length, are seen to pass between the knobs 1 and 2, showing that there are violent electrical oscillations, not only in the secondary circuit itself, but in any conductor in contact with it. This experiment shows even more clearly than the previous one that the rapidity of the oscillations is comparable with the velocity of transmission of electrical disturbances through the copper wire, which according to all the evidence at our disposal is nearly equal to the velocity of light.

In order to obtain micrometer sparks some millimeters in length a powerful induction coil is required, and the one used by Hertz was 52 centimeters in length and 20 centimeters in diameter, provided with a mercury contact breaker, and excited by six large Bunsen cells. The discharger terminals consisted of brass knobs 3 centimeters in diameter. The experiments showed that the phenomenon depends to a very great extent on the nature of the sparks at the discharger, the micrometer sparks being found to be much weaker when the discharge in the secondary circuit

1. From the *Electrician* (London).

took place between two points, or between a point and a plate, than when knobs were used. The micrometer sparks were also found to be greatly enfeebled when the secondary discharge took place in a rarified gas, and also when the sparks in the secondary were less than half a centimeter in length, while, on the other hand, if they exceeded 1½ centimeters the sparks could no longer be observed between the micrometer knobs. The length of secondary spark which was found to give the best results, and which was, therefore, employed in the further observations, was about three-quarters of a centimeter.

Very slight differences in the nature of the secondary sparks were found to have great effect on those at the micrometer, and Hertz states that after some practice he was able to determine at once from the sound and appearance of the secondary spark whether it was of a kind to give the most powerful effects at the micrometer. The sparks which gave the best results were of a brilliant white color, only slightly jagged, and accompanied by a sharp crack.

The influence of the spark is readily shown by increasing the distance between the discharger knobs beyond the striking distance, when the micrometer sparks disappear entirely, although the variations of potential are now greater than before. The length of the micrometer circuit has naturally an important influence on the length of the spark, as the greater its length the greater will be the retardation of the electrical wave in its passage through it from one knob of the micrometer to the other.

The material, the resistance, and the diameter of the wire of which the micrometer circuit is formed have very little influence on the spark. The potential variations cannot, therefore, be due to the resistance, and this was to be expected, for the rate of propagation of an electrical disturbance along a conductor depends mainly on its capacity and coefficient of self-induction, and only to a very small extent on its resistance. The length of the wire connecting the micrometer circuit with the secondary circuit of the coil is also found to have very little influence, provided it does not exceed a few meters in length. The electrical disturbances must therefore traverse it without undergoing any appreciable change. The position of the point of the micrometer circuit which is joined to the secondary circuit is, on the other hand, of the greatest importance, as would be expected, for if the point is placed symmetrically with respect to the two micrometer knobs the variations of potential will reach the latter in the same phase, and there will be no effect, as is verified by observation. If the two branches of the micrometer circuit on each side of the point of contact of the connection with the secondary are not symmetrical the spark cannot be made to disappear entirely; but a minimum effect is obtained when the point of contact is about half way between the micrometer knobs. This point may be called the null point.

Fig. 2 shows the arrangement employed, e being the null point of the rectangular circuit, which is 125 centimeters long by 80 centimeters broad. When the point of contact is at a or b, sparks of from 3 to 4 millimeters in length are observed, when it is at e no sparks are seen; but they can be made to reappear by shifting the point of contact a few centimeters to the right or left of the null point. It should be noted that sparks only a few hundredths of a millimeter in length can be observed. If, when the point of contact is at e, another conductor is placed in contact with one of the micrometer knobs the sparks reappear.

Now, the addition of this conductor cannot produce any alteration in the time taken by the disturbances proceeding from e to reach the knobs, and, therefore, the phenomenon cannot be due simply to single waves in the directions $c\,a$ and $d\,b$ respectively, but must be due to repeated reflection of the waves until a condition of stationary vibration is attained, and the addition of the conductor to one of the knobs must diminish or prevent the reflection of the waves from that terminal. It must be assumed, then, that definite oscillations are set up in the micrometer circuit just as an elastic bar is thrown into definite vibrations by blows from a hammer. If this assumption is correct, the condition for the disappearance of the sparks at M will be that the vibration periods of the two branches e 1 and e 2 shall be equal. These periods are determined by the products of the coefficients of self-induction of these conductors into the capacities of their terminals, and are practically independent of their resistances.

In confirmation of this, it is found that if when the point of contact is at e and the sparks have been made to reappear by connecting a conductor with one of the knobs, this conductor is replaced by one of greater capacity, the sparking is greatly increased. If a conductor of equal capacity is connected with the other micrometer knob the sparks disappear again; the effect of the first conductor can also be counteracted by shifting the point of contact towards it, thereby diminishing the self-induction in that branch. The conclusions were further confirmed by the results obtained when coils of copper wire were inserted into one or other, and then into both of the branches of the micrometer circuit.

Hertz supposed that as the self-induction of iron wires is, for slow alternations, from eight to ten times that of copper wires, therefore a short iron wire would balance a long copper one; but this was not found to be the case, and he concludes that, owing to the great rapidity of the alternations, the magnetism of the iron is unable to follow them, and therefore has no effect on the self-induction.

In a note in Wiedemann's *Annalen*, vol. xxxi., page 543, Dr. Hertz states that since the publication of his paper in the same volume, he had found that von Bezold had published a paper in 1870 (Poggendorff's *Annalen*, vol. cxl., page 541), in which he had arrived by a different method of experimenting at similar results and conclusions as those given by him under the head of Preliminary Experiments.

ABSTRACTS AND EXTRACTS.

FLASHED FILAMENTS IN LAMPS.

HAS anyone observed that the result of the so-called flashing process is necessarily to produce a conductor which tapers to the ends? Wherever the temperature of the surface is hottest, for any cause, there a more rapid deposition of carbon will take place; and where the temperature is lower a less rapid deposition will occur. Now, consider a simple arched conductor, which we will suppose to be of initially equal section from end to end. When rendered incandescent, the end portions being connected to non-incandescent mountings, will be cooled by them. Those parts which are subjected to the end-cooling will necessarily be at a lower temperature, and will therefore receive a less thick deposit of carbon. Again, in the case of conductors which are bent, not merely into an arch, but into a loop of one or more turns. Those portions of the conductor which lie near to one another will radiate to one another, instead of merely radiating out to cooler objects. They will consequently help to raise one another's temperature. Were the conductor, then, initially a wire of perfectly uniform section, those parts which are thus mutually heated will tend to receive a thicker coating of deposited carbon than the straight limbs leading to the mounts.

In every case the result of flashing will be to so build up the size of the conductor that every part shall glow with equal radiance, in spite of its accidental position, whether subjected to a cooling effect or to a heating effect from the adjacent portions of the lamp. Flashing will not, as often alleged, reduce all portions of the conductor to equal size or equal resistance per unit of length, and it weakens the conductor mechanically by leaving it thinner near its mountings.

The existence of this tapering structure can be actually observed by the eye in some flashed lamps, and is capable of measurement by a micrometer gauge.

The following measurements were made by the writer upon a flashed 105-volt "Victoria" lamp. Measurements bracketed together were made at the same point in two diameters approximately at right angles to one another :—

DIAMETER IN MILLIMETERS.

At bow of loop	.145 .150	mean .1475
Half-way down limbs	.150 .140	" .1437
" " "	.135 .150	
At end, near mount	.095 .105	" .1012
" " "	.110 .105	
At other end, near mount	.090 .100	
" " " "	.105 .100	

In another similar lamp the mean diameter of bow and limbs of the arch was .130 millimeter, and that of the ends close to the mount .100.—PROFESSOR SILVANUS P. THOMPSON in *The Electrician* (London).

THE ELECTRICAL RESISTANCE OF IRON.

IN text books the resistance of commercial iron is generally given as 6.56 times that of copper, but according to the results of recent experiments made by Mr. W. H. Preece, F. R. S., it is actually only 6.034 times that of copper. The exact determination of the resistance of iron is of considerable importance, especially now, when through the operations of the copper syndicate the price of this metal has been forced up to a figure which precludes its use for many electrical purposes. The following table, which we extract from a recent post-office circular, gives the specific resistance of various metals. The resistance in C. G. S. units of a cubic centimeter at 60° F. is as follows :—

Silver	1609
Copper	1642
Pure iron	9753
Commercial iron	9907

The increase of resistance with temperature from t to t_1° F, for iron can be determined by the formula

$$R = r\,(1.0027)^{t_1 - t}$$

where r is the resistance at t° and R at t_1°. If the temperature be given in centigrades, the formula is

$$R = r\,(1.0048)^{t_1 - t}.$$

For telegraph lines, "low" and "high" resistance iron wire is now used, the former being either charcoal iron or a special blend, and the following table gives the mechanical properties of these wires :—

Gauge No.	Weight per mile.	Diameter.	Breaking weight. Low resistance. Blend.	Breaking weight. Low resistance. Charcoal.	Breaking weight. High resistance.	Elongation per cent. Low resistance. Blend.	Elongation per cent. Low resistance. Charcoal.	Elongation per cent. High resistance.

THE TELEPHONE IN SWEDEN.

IT may be doubted whether in any other country in the world the telephone has made such progress as in Sweden. Thus a Swedish technical journal publishes statistics up to 1886 showing that the City of Stockholm, in proportion to the number of inhabitants, takes precedence in respect of the number of telephones in use over 12 European capitals and three great cities in the United States, as the following figures purport to show :—

	Number of inhabitants.	Number of apparatus.	Per 10,000 individuals.
Stockholm	215,000	4,978	232
Berlin	1,280,000	4,248	33
London	4,765,000	4,193	9
Paris	2,800,000	4,054	14
Rome	300,000	2,054	68
Copenhagen	274,000	1,336	49
Amsterdam	335,000	1,195	36
St. Petersburg	850,000	1,100	13
Vienna	1,200,000	946	8
Brussels	380,000	803	21
Helsingfors	46,000	575	125
Madrid	478,000	270	6
New York	1,500,000	3,700	25
Chicago	600,000	3,500	58
Brooklyn	650,000	2,375	37

The journal adds that since then the number of telephones used in Stockholm has greatly increased ; but for some cities no statistics more recent are available.—*Electrical Review* (London).

THE METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED), LONDON.

THE WESTINGHOUSE STATION IN SARDINIA STREET.

AT an extraordinary general meeting of the shareholders of the Metropolitan Electric Supply Co. (Limited), on Dec. 4, 1888, the following address was made by the chairman of the company, Sir John Pender, K. C. M. G.

Gentlemen :—We have called you together to-day for two purposes—first, to inform you as to the progress the company has made since August last and its present position and prospects ; and, secondly, to put before you a resolution approving an agreement made by the board, under the power of the articles of association, to vary the original agreement entered into between this company and the Whitehall company for the purchase of the property and the undertaking of the Whitehall company. And first, with respect to the work done. You are aware that the company took over from the Whitehall company the important works and installation which the latter had established at Whitehall avenue. That station, which has about 10,000-light capacity, was opened on the 5th October last, and the directors had hoped that the full capacity of lighting would be taken up by customers in seven or eight months. Instead of this, the full capacity of the station is taken up already. In about two months orders were booked for nearly 9,000 lamps, and the mains for connecting them are being laid as fast as possible. The Avenue Theatre, the Hotel Victoria in Northumberland avenue, and other places have been lighted for some time, and the managers have written expressing their satisfaction with the supply, and among the more recent contracts secured to be worked from the Whitehall station are the Grand Hotel, Messrs. Hampton's large furniture warehouses in Pall Mall, St. Martin's Church, and other places. The company's mains are being laid underground throughout the whole of the Charing-cross district, and have already been laid across Northumberland avenue, West Strand, and Trafalgar square, without causing any appreciable interruption to the traffic. Mr. Gordon informs me that the guaranteed revenue from the contracts made and to be carried on from the Whitehall works is £13,500 a year, and that other contracts, expected to be completed in a few days, will be another £1,000, making altogether £14,500. The working expenses, including rent, salaries, wages, and 10 per cent. for depreciation, are estimated at £6,000, leaving a profit of £8,500 a year, on these installations, which, I think, is fairly satisfactory, seeing that the capital represented by these works is not much over £40,000. As to the Sardinia street works, the buildings in Sardinia street are in hand, and a large body of men are employed on them. We have put up a map here in which you see the Sardinia street station. I may say without any hesitation or fear of contradiction that that station will be one of the most important in London. It embraces the important residential property about Bloomsbury, the shops, hotels, and large restaurants in Holborn, the important newspaper, publishing and printing establishments about Fleet street, and the banks, shops, and numerous buildings in the East Strand district. That station will, I think, have altogether 50,000 lights, and so far as we can see now and judge from

the inquiries that are made, it will not be a long time after the installation is completed before that will be fully occupied; and if the results upon the 50,000 lights are at all in proportion to what we now see from the practical working of the Whitehall works, I think we may congratulate ourselves on being in a position to make very handsome dividends. I may mention that the machinery for this station has been ordered from the Westinghouse company, and the bulk of it will be delivered in a very short time. The object in ordering this machinery from the Westinghouse company is this—that they have put down in America 116 installations, all of which have been successful, and the principle we have gone upon—what has been the policy of this company, because we have not been idle during the last six months—has been to take the very best thing in existence, and to utilize it for our purposes. This American system is considered almost perfect, as far as it has gone. We are inviting tenders from English contractors for another installation, and so we shall work one against the other, and we shall have the full advantage of what I may call contractors' competition. I think the result of that will be to give us the best thing of the kind up to the present moment. I do not mean to say that in electricity, as in other things, there is not very great progress. You will see that that is the case when I tell you that it is scarcely 10 years ago since electric lighting was a laboratory experiment, whereas it is now almost becoming universal. I may go further and say this: It is not more than 25 years since submarine telegraphy was first introduced, and there is now £40,000,000 sterling in the bottom of the sea, the major portion of it paying a fair dividend. That shows that we do not know to what extent electricity can be carried; but, so far as we have gone, it seems that the electric light is to be the light of the future. I have no hesitation in saying, if you look at the prospectus we put before you—it was based on a good deal of experience—you will find that what we said in regard to the American installations ought to be thoroughly borne out also in regard to English installations. The company also took over from the Whitehall company the extensive and valuable property for electric lighting purposes, the Waterloo bridge wharf, which is admirably adapted for supplying the whole of the Strand district, and which can take the machinery required for working 150,000 lamps. That, I think, will be perhaps the largest installation in our system. I want you to understand that we have not gone, in the slightest degree, upon a speculative or experimental policy. We are laying down installations which we know will be successful, so far as the mechanical part of them is concerned, and we believe that the light will be fully taken up by the public; and, therefore, I think we are not over sanguine in looking forward to very successful results. That installation is one which, I hope, will, before another year is out, be in active operation. We know that there are very formidable competitors in the market at the present moment. I greatly admire the enterprise of the Grosvenor Gallery combination, the gentlemen connected with which are of the highest eminence. They have great practical scientific knowledge among them, but they are trying the biggest experiment ever tried in electric lighting, so I am informed by scientific men. I hope their experiments may be successful. I like to see these great efforts of science successful, and I believe if this experiment is successful it will be a very remarkable step in electrical progress. We have been more cautious, probably more prudent. We are not putting all our eggs in one basket. We are so putting our different installations that we can work them collectively or separately; consequently we are not likely to break down as a whole. You can see the object of that, and we have acted upon the advice of our eminent scientific advisers. Therefore, every installation of ours will stand alone, but every installation will stand shoulder to shoulder with its neighboring installation if so required. Since August last (I have said that we have not been idle) the directors have secured several other sites for works. One is Greenmore wharf, a large wharf adjoining Southwark bridge, which is suited for lighting the City of London proper. We have also obtained a site in Southmews, Manchester square, for the Marylebone district. Negotiations are proceeding for other sites. The specifications for the machinery for the Greenmore wharf have been sent out, and tenders are expected in a week or two from various responsible English firms. Specifications for the other sites will go out immediately. With regard to the Strand district, the company has secured a monopoly of the lighting of the new Salisbury estate, consisting of Salisbury and Cecil streets, for the ground of which alone a sum of £200,000 has recently been paid. That will probably be one of the most remarkable improvements in London. I cannot say much more with regard to our prospects. In the summer it was said they were encouraging, and I think if I went over article by article in the prospectus put before you, I could justify every item in it. The second portion of our business to-day I hope will also be satisfactory, because it is very much for the benefit of the company's interests, though probably not so much to the satisfaction of others, who have been working for the last two or three years, and who consider themselves very badly paid indeed for their work and property. I may say at once that the short result of what we ask you to confirm to-day is to reduce by just one-half the purchase money payable by the company for the property and rights which they agreed to take over from the Whitehall company. The price is reduced from £79,000, the sum named in the prospectus as having been fixed by the vendors, the Whitehall company, to the very modest sum of £40,000. This, you will see, is practically reducing the purchase money by one-half, and I am sure every shareholder in this company will be glad that this reduction is to be made. The vendors are willing to make the reduction, though they are by no means satisfied with the decision that Sir Frederick Bramwell and Sir Whittaker Ellis have arrived at with respect to the value of the property. It was, of course, to be expected that the vendors would take a more favorable view of their undertaking than what I may call cold-blooded but very experienced gentlemen who sat down to value what was placed before them. The vendors made their arrangements with the company at a time when there were really no shareholders but themselves and their friends in the company. No man could then, nor can even now, estimate absolutely what is the value of the undertaking we have purchased. I have told you to-day of our prospects. Probably a year or two hence our stock may be worth twice or thrice what it is to-day, so you see how difficult it is to value a thing which has not been fully realized. Therefore, in this valuation, though it is not so stated, probably nothing has been taken into consideration as to the prospective value of the company. I do not know what was in the minds of the valuers, and they have, perhaps, wisely given no reason for their decision, but from the course of inquiries which they have made very carefully in respect to the properties actually transferred I have no doubt they have omitted from their calculations these elements of future value which the vendors not unreasonably considered so important. I may add that the vendors would be perfectly willing to take back their properties if the company did not desire to go on with the purchase; but I believe I am right in saying that every member of the board is convinced that the property is well worth, and more than worth, the sum we have now decided to pay for it. One other matter ought also to be mentioned, that is with respect to the provisional order which the board of trade had granted before the prospectus was issued. This provisional order gave to the company valuable rights over the parish of St. James's, Westminster, and St. Martin's-in-the-Fields; and when the Duke of Buckingham, as chairman of committees of the house of lords, refused to suspend the standing order which prevented the second reading of the government bill to confirm that provisional order, the board of trade promised to use their good offices to support a private bill to enable the company to secure the confirmation of that provisional order in the next session. The loss of this provisional order, in the sense I have mentioned, occurred between the time when the agreement was made and the prospectus prepared and the date of its actual issue, and I think the valuers must have made a large reduction from the original price on account of the unfortunate slip, which was occasioned by no fault of the promoters but through the delays in parliament. When the prospectus was issued, and the shares were so readily and so largely subscribed, and so many new shareholders came into the company, the directors sat down to consider the position and the course they should take in consequence of the changes which had occurred, and they came to the conclusion that there should be, in the interests of all parties concerned, an independent valuation of the property which the company was to purchase. Several of the directors were themselves interested in the properties which had been acquired and were to be sold by the Whitehall company, and this made it the more necessary that such a valuation should be taken. The South Metropolitan Co. was threatened with opposition by the Whitehall company, and it was really this that brought about the combination of the two parties, one represented by Sir George Elliot and his friends who had taken a deep interest in this question, and the other by Mr. Balfour and his friends, who had invested largely in the Whitehall court enterprise, and who had founded the Whitehall Electric Co. The agreement referred to in the circular, which has been sent to you, dated 12th December, 1888, will now be read to you by the solicitor. It has been made especially under power of the articles of association, which contain an important clause authorizing this being done. The solicitor will now read the agreement.

Later, at the same meeting, Sir John Pender made further remarks, as follows:—

Now, gentlemen, we have given you to-day a straightforward statement, and I wish to give you also a little further information, so that on leaving this room you will understand that the gentlemen connected with this enterprise have made up their minds to make it go ahead. We believe the time has come, and that there is a great deal of good useful paying work to be done with electric lighting. This is the further information I will give you. The company has given notice of a bill in parliament to obtain parliamentary powers to carry on the works for St. James's, Westminster, St. Martin's-in-the-Fields, and Waterloo bridge, which will include the ground covered by the provisional order which was obtained last summer, but which was not confirmed by parliament, although the board of trade did all in their power to get the bill passed. Notices have also been given for provisional orders in four districts—Mid-London, North London,

South London and West London. It may be that we shall not proceed with all these, but we thought it wise to give the notices, without which we could not proceed. In view of all the works executed and in hand, and what is proposed to be done in the future, the directors think the prospects of the company, as put before you to-day, are very encouraging indeed. There is another point. Some people have said to me, "But there are more electric lighting companies in existence than can possibly be required." But the population of this mighty city is 5,000,000 of people, and if the electric light is successful (and I believe it must become the light of the future), we shall require to spend £34,000,000 to £35,-000,000 sterling before we can do the work required. Therefore, when I find respectable people—people of high position having money to spend—coming forward to take part in this work I hail them with great satisfaction. There is plenty of good paying work for us all. As I said before, electricity is yet in its infancy, and the more that science can be brought to bear upon it the more we shall have of this light. The light is doing a great sanitary work, and with its use the air remains pure, and there is less heat. I have not a word to say against gas. I believe that gas, being the essence of heat from coal, has a great deal of work before it, but in another field than that of lighting. Those interested in gas must look to apply it to other purposes. The light of the future is to be the electric light. That finishes the business of the day, gentlemen.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Decision for the Board of Electrical Control Against the U. S. Illuminating Co.; the Latter Co. Sues the Commissioners for Damages.—Annual Report on the Subways.—Rapid Transit Sought for New York.—An Electrical Course at Columbia College.—Mr. E. N. Dickerson's Lecture at the Electric Club.—Comments on the U. S. Supreme Court Decision in the Bate Case.—Prospective Removal of the Westinghouse Electric Co.'s General Office to New York.

JUDGE LAWRENCE, of the Supreme Court, has sustained the position taken by the Board of Electrical Control in the suit brought against that body by the United States Illuminating Co. The company will now be compelled to abide by any and all orders of the board without questioning its jurisdiction or right. Judge Lawrence alluded to the wisdom of the legislature in giving full power to the board to act. He thought that while the Illuminating company brought forward the testimony of undoubted experts that the conduit was not feasible or practicable, the evidence produced by the board—notably the affidavit of the city electrician of Chicago—was equally strong and effective.

A few days after this decision, the United States Illuminating Co. brought suit for damages against Commissioners Hess, Moss and Gibbons in the sum of $250,000.

The Board of Electrical Control has made its second annual report to the Governor, the previous reports having been made by the old Subway Commission, which was practically the same body. The total length of trench excavated in the city is 240,-155 feet, and the total length of single duct for telegraph and telephone service is 2,287,880 feet, less 325,429 feet for distributing service and connections. Estimating the duct as having a capacity of eighty wires, the total mileage of wire provided for is 34,665. It is estimated that the conduits for electric light and power service have a capacity for nearly 600 miles of wire, exclusive of the Edison system. The number of poles removed is given at 776, and 946 miles of wire have been taken down. The Metropolitan Telephone & Telegraph, the Western Union, the Brush and the Edison companies, and the city fire alarm telegraph have in all 4,453 miles of wire underground, but it is admitted that there are to-day more miles of wire overhead than existed a year ago.

Our new mayor announces his purpose to enforce the Subway law. He has assumed the presidency of the board, but no radical change of policy has yet been announced. At a recent meeting of the board, the Consolidated Telegraph and Electrical Subway Co. reported that 2,287,880 feet of duct had been thus far constructed for telegraph and telephone wires, and 316,776 for Edison incandescent lighting. About 45 miles of trench had been opened and filled. The miles of electrical wires in the subway on Jan. 1 were :—

	Miles.
Metropolitan Telegraph and Telephone Co.	4,062.32
Western Union Telegraph Co.	39.08
Brush Electric Light Co.	8.87
Edison company	192.23
New York City Fire Telegraph	101.02

The subway is now completed between the Battery and Fifty-eighth street in Broadway, also along Church street, College place, West Broadway, South Fifth avenue and Sixth avenue. Other routes, solely for electric light service, extend from Fourteenth to Fifty-eighth streets on Broadway, from Eighteenth to Fifty-eighth streets on Sixth avenue, and on various cross-town streets.

Since the expose of the Sugar Refinery Co.'s affairs, the *Herald* has instituted a diligent search for electrical sensations. In its issues of the 18th and 19th of January, it charges Mr. E. T. Gilliland and John C. Tomlinson with retaining a quarter million dollars rightfully belonging to Mr. Thomas A. Edison for the sale of certain rights to the phonograph. The libel formed the subject of an Associated Press report, and seems very likely to cause trouble for some one. The parties concerned refuse to make any statements. It is however, known that Messrs. Gilliland and Tomlinson have ceased all connection with the Edison interests. Mr. Gilliland has interested himself with Mr. O. E. Madden in the Empire City Electric Co. and the Non-Magnetic Watch Co. of America.

Anyone who has a plan for providing New York with rapid transit will be welcomed with dollars and honors by our new Mayor. Mr. Frank J. Sprague, in his lecture before the Institute of Electrical Engineers last year, did not overestimate what has now become a most serious question. The crowding on the elevated roads is little short of disgraceful. At least seventy-five per cent. of the passengers travel several miles, and the large number of stoppages necessitates an enormous number of people devoting a considerable portion of each day in getting to and from their places of business. A recent bill in the legislature for an "L" road on Broadway called forth most emphatic protests.

The trustees of Columbia College have decided to establish a department of electrical engineering. They have provided for the appointment of an instructor in electrical engineering and an assistant for teaching the theoretical branches of mathematical physics as applied to electricity and its relations to heat, and magnetism.

A motor, closely allied to that of Mr. Keeley, has made its appearance in this city. Mr. E. D. Speer, of Cincinnati, is the inventor and promoter. Mr. Speer modestly claims to save 95% of the power of the fuel. His concern is called the Non-Exhaust Steam Engine Co.

The committee of the Board of Trade and Transportation has presented its bill to the legislature regulating telephone rates to $72.00 per year in cities of over 500,000 inhabitants, and $36.00 in all other cities.

Mr. E. N. Dickerson, well known to the electrical fraternity through his work as counsel for the American Bell Telephone Co., lectured before the Electric Club Jan'y 17th on "The Steam Engine." Mr. Dickerson called attention to the enormous loss in the conversion of coal into steam with our present type of engines, pointing out that in electrical engineering the question of cost of supplying current is one most largely dependent upon the cost of fuel.

The jubilant tone of the observations printed by the daily press as coming from President Johnson and Secretary Hastings of the Edison Electric Light Co. in regard to the commercial effect of the Supreme Court decision of January 21, in the Bate case, does not meet with an altogether hearty response from the legal department. On the contrary, the decision proved, from the latter point of view, to be little better than a Dead Sea apple. The best efforts of able counsel, to say nothing of a large amount of money, were employed to secure an early decision of this case, in the hope that the Supreme Court would hold that the foreign patent limitation of the statute related to the date of application and not to the date of issue of an American patent. Almost the whole force of argument of counsel was directed to this one point, which, had it proved successful, would have freed Mr. Edison's patents from all limitations, and possibly have placed the competitors of the Edison company practically at its mercy. But the Court, it seems, skillfully avoided the necessity of passing upon this point, and so left the law exactly where the counsel of the other electric companies have all along contended it was. It was a bitter disappointment to the Edison interests, and one which is not materially assuaged by the circumstance that some of the competing concerns will be materially benefited by the effect upon their patents of the favorable decision on the remaining point.

It is rumored that in consequence of the recent consolidation of interests between the Westinghouse and United States companies, the general offices of the first named company will be removed to this city in the course of two or three months.

NEW YORK, January 26, 1889.

.... WITH a series motor, or a motor excited by a constant current, you may vary the load as much as you please and the volts will vary, but the current will remain perfectly constant; the pressure may be made to vary as you like, and the current will remain perfectly constant.—*Professor George Forbes.*

.... THE great advantage of high-speed engines, is that the steam has no time to condense, or, rather, that very little of it is condensed in comparison with the amount utilized.—*Gisbert Kapp.*

PHILADELPHIA.

A City Electric Lighting Plant Under Discussion.—The Street Lighting Contracts for the Next Year.—The Suit of the State of Pennsylvania Against the Western Union and Baltimore and Ohio Telegraph Companies; a Statement by Dr. Norvin Green.

THE probability that the special committee of councils investigating the subject of electric lighting for the city will report in favor of the municipality establishing its own plant, and that this recommendation will lead to a discussion of the entire matter in councils, has raised the question as to the ownership of the numerous abandoned conduits under some of the streets. There are several of these structures under Chestnut and Market streets, which might possibly be utilized for the city's wires if these should ever be buried.

City treasurer-elect Bardsley said that while he did not wish to express a positive opinion without examining the ordinances, he was confident that the conduits had become the property of the city by the failure of the companies to make use of them within the time limits fixed by the ordinances. "It is doubtful, however," he said, "whether any of them are of any value. The city has the right to put in two or three wires in the conduits laid in Market street by the Western Union Telegraph and Bell Telephone companies, and these might be used to advantage if the city should establish its own plant and bury its wires." Mr. Bardsley favored the city doing its own lighting if the companies shall not come down in their prices.

Estimates as to the cost of the proposed plant vary widely. The Pennsylvania railroad found that it could secure a plant of 1,000 arc lamps capacity for $100,000, and the cost to the city would probably be little greater. The necessity for more lamps is generally admitted, and the plant required would be of at least 2,000 or 3,000 lamps capacity. The cost of this is estimated at anywhere from $250,000 to $500,000.

The bids for illuminating the streets by the electric arc lamps next year were opened a few days ago by director Wagner and chief Walker, of the electrical department.

According to the specifications of the contracts, the director can have any light tested and rejected, if not up to the standard. The lights are to burn from sunset to sunrise. It is further specified that lights which burn less than nine hours each night from September to March 31, and less than six hours from April 1 to August 31, will not be paid for. The failure of the lights for two nights, or any other violation of the specification will cause the annulment of the contract.

All the bidders will receive contracts, as each company bid only for the territory it covers. There will be an average decrease in cost of 2½ cents for each lamp per night from the price paid during the current year.

There is an appropriation of $130,000 for the purpose of paying the expense incurred by the electric lights. The bids are as follows:—

Germantown Electric Light Co. (Thomson-Houston) old borough of Germantown, 2,000 c. p., 55 cents (same as this year).

Frankford Electric Light and Power Co. (Thomson-Houston), Bridge street below Asylum turnpike and east of it, 55 cents (same as this year). Northern Electric Light Co. (Thomson-Houston), north from and not including Poplar street, and east from and including Second street to the Delaware river, 1,200 c. p., 48 cents (last year, 49 cents).

Brush Electric Light Co., Brush system, 2,000 c. p., between the Delaware and Schuylkill rivers, south of Washington avenue, 54 cents; from the south side of Spruce street to the north side of Washington avenue, between the rivers, 47½ cents; between south side of Market street and north side of Spruce, and Delaware and Schuylkill, 45 cents; between north side of Market street, south side of Callowhill, west side of Broad and Schuylkill river, 47½ cents. West Philadelphia, 50 cents.

United States Electric Light Co. (U. S. system), 2,000 c. p., between the north side of Market street and north side of Poplar, east of Broad to the Delaware, 49 cents (this year 50 cents). Philadelphia Electric Lighting Co. (Thomson-Houston, north side of Callowhill street and Erie avenue, east side of Broad street and the Schuylkill river, 45 cents (this year, 47½ cents). Between south side of Eighth, Callowhill and north side of Poplar from Eighth to Broad, 47½ cents (this year 52½ cents). Between the north side of Callowhill street and Erie avenue, east side of Broad and Schuylkill river, 45 cents (this year 69½ cents).

Wissahickon Electric Lighting Co. (American system), 700 to 800 c. p., between Allegheny avenue, twenty-eighth ward, and Leverington avenue, twenty-first ward, 55 cents.

The joint special committee appointed to ascertain if a more desirable method can be adopted by the city for lighting the streets with electric lights, held a meeting a few days since.

The city at the present time is paying $129,000 a year for the lighting of 755 electric arc lights on the streets.

This is said to be excessive, and for the sum of $300,000 it is claimed that the city could put in a plant that would provide 3,000 lights at an expense of $90,000 a year.

When the meeting was called to order it was moved that, considering that the contracts for '89 had been awarded, that the meeting be postponed for the present, as there was no need fo hurrying the matter.

On the other side, it was urged that it would take some time to consider the matter, and require minute consideration, as it is very important, and if the committee should act favorably on the subject it will take nearly a year to construct the plant.

Chief Walker of the electrical department said, in answer to a question, that it was the intention of the electrical bureau to test all the lights next year, and if they were not up to the standard, the company supplying the same would receive no money for the lights.

On a motion to consult with the directors of public safety and public works and obtain all the information possible on the matter, the meeting adjourned to meet again at the call of the chair.

City-solicitor Warwick and councilmen generally will watch with interest the suit that has been instituted by attorney-general Kirkpatrick against the Western Union and the Baltimore and Ohio Telegraph companies and the Baltimore and Ohio company of Pennsylvania, with the view of having their property and franchises forfeited to the state for violating the state constitution.

The charge against the Western Union is that it bought a competing line, and the Baltimore and Ohio company is charged with selling out to a business rival. The attorney-general has become possessed of irrefutable information that Jay Gould and his colleagues on October 5, 1887, bought out the entire capital stock of the Baltimore and Ohio concern for $5,000,000, though the par value of the same was but $3,875,000. The attorney-eneral has asked for a writ of *quo warranto* to summon the companies before the court to show by what authority they continue business in the state and why all their franchises, rights and privileges should not be forfeited to the state. Judge Simonton granted the writ and made it returnable on January 29.

When the Baltimore and Ohio company obtained permission from councils to erect its poles and string its wires in this city the company gave a bond of $50,000 conditioned that it should never pass into the hands of a rival concern. City-solicitor Warwick has taken steps to sue on the bond, but has met with many obstacles, chiefly on account of his inability to produce evidence showing that the actual purchase of the Baltimore and Ohio plant was made by the Western Union company.

Dr. Norvin Green, the president of the Western Union, in speaking about the suit said:—

"There is no good ground for the suit, and we are not at all disturbed by it. Just who the parties that have instituted the suit are I do not know, as I have not seen the papers. At the time of the purchase of the Baltimore and Ohio property by us we guarded against the very points that are raised by this suit. Under the United States law of 1886, all telegraph companies were given the right to operate their lines in all states, and even if there is a Pennsylvania state law, as is alleged, it would have no effect in the face of the United States law. The United States Supreme Court has decided over and over again that telegraph business is interstate commerce, and cannot be interfered with by state action or statute.

There is no consolidation of the Western Union and the Baltimore and Ohio Telegraph companies. The latter is still maintained as a separate and competing company. Then again the Western Union, when it made the purchase, did not buy that portion that was operated under the Pennsylvania charter. The Baltimore and Ohio parent company was chartered under the Maryland laws. In each one of the other states where the company built lines, separate state charters were secured, and each of these separate companies was leased by the original company. The Pennsylvania company was not included in the purchase, we expressly refusing to purchase, as we were aware of the stringent state charter and did not care to enter into any controversy over it."

PHILADELPHIA, January 18, 1889.

BOSTON.

Municipal Recommendations in Several Cities.—A Satisfactory Burglar Alarm Test.—Quincy Telephone Subscribers Tired of Disturbance from Electric Light Wires.—Damages Secured for Bad Telephone Service at Naugatuck.—Boston Aldermen Satisfied with Telephone Rates.—The Western Union Telegraph Co. Resenting Taxation.—Report of Committee of Aldermen on Overhead Wires.—Trouble at Malden Between the Electric Light and Telephone Companies.—Sprague Electric Cars Running on the Brookline Branch of the West End Railway Co.

IT is interesting to observe the recommendations of the newly inaugurated mayors of our state, and to note among others the following: The mayor of Cambridge recommends the introduction of police signals.—The newly-elected mayor of Worcester suggests that their police signal system be extended.—His honor of Quincy, thinks there should be an improvement in the fire alarm system.—Police signals are declared a public necessity by the mayor of Chelsea.—In Lowell, the city of spindles, the newly-elected chief officer thinks that the police department should have

a signal system.—Hon. E. S. Bradford, of Springfield, believes in investigating the quality and expense of lighting by gas and electricity, and the expense of all-night burning.—Mr. Jackson, of Fall River, recommends the adoption of police signals; electric lights, he said, are a great improvement over gas, and it is well to increase their number as fast as the city's finances will permit. The old town of Newburyport has a mayor; he thinks the electric lights in the streets should be burned later than midnight.—Perhaps he belongs to a lodge. In the ancient borough of Watertown, a police signal system is recommended by the new comer. In all the inaugurals that have come to hand some application of electricity is commended or recommended. It is significant to observe the general request for police signals.

At a meeting of the directors of the Brookline National Bank in Brookline, on the afternoon of the 8th inst., one of the directors thought it would be a brilliant idea to test the burglar alarm—the bank being connected with the police station by a private wire. The alarm was set off, and within an incredibly short time police officer Watson was standing before the directors. The test was satisfactory. A good thing to do once in a while.

About 25 telephone subscribers of Quincy, including eight physicians, have notified the telephone company that they shall cease to be subscribers if the telephone service is not improved by altering its relations with the electric light wires.

Recently E. A. Sanders, the general manager of the G. M. R. Shoe Co., of Naugatuck, won a suit at Naugatuck against the Southern New England Telephone Co. Justice Gibb decided for the plaintiff in $100 and costs. The suit was brought for failure to properly transmit a message while the plaintiff had urgent need for good service, the call being for a physician. Inattention and insulting language on the part of a telephone operator in the main office was alleged.

On the 26th of December, alderman McLaughlin, from a special committee appointed to investigate telephone rates as paid by the City of Boston, made a report, in which comparisons are made with prices paid in other large cities. The conclusion of the committee is that the City of Boston has a more favorable arrangement for telephone service than most other cities.

At the last meeting of the board of aldermen for 1888, a communication was received from the mayor, returning without his signature the order granting the New England Telephone and Telegraph Co. leave to attach its wires to poles on the new Harvard bridge, the mayor claiming that the control of the bridge rests with the commissioners of Harvard bridge. The order was reconsidered, and on motion of C. W. Smith, was referred to the next board.

Assistant attorney-general Henry C. Bliss, on behalf of the Commonwealth, and George S. Hale for the defendant, have been taking testimony in the case, in the United States Circuit Court, of the Commonwealth *vs.* the Western Union Telegraph Co., for unpaid taxes for the years 1886-7, amounting to about $30,000. The company declines payment on the ground that it pays a local tax on real estate in New York; and it also contends that the levy made by the Commonwealth is a tax upon interstate business, and, furthermore, that it is a tax upon a federal franchise, which is contrary to law, as laid down in a national book case.

The committee of the Boston board of aldermen, appointed October 8th, last "to enquire into and report what action can be taken by this board to protect the lives of the firemen and property from danger by the overhead electric wires," after visiting New York and other cities, have reported in substance that, from the information obtained, they are of the opinion that there is no difficulty in placing all heavily charged wires underground that are now in use in our city, and the only serious question in this regard is that of expense. These wires as at present located are undoubtedly very dangerous to the public, and especially so to firemen in the discharge of their duties at fires, and fatal accidents occur frequently every year from contact with these exposed wires, and will continue so long as the overhead system is allowed to exist. The committee, therefore, recommend that immediate steps be taken by the board of aldermen to require that all heavily charged wires be placed underground, and that application be made to the general court for the necessary authority. The report was ordered printed, and referred to the new board of aldermen.

In consequence of the interference of strong current in electric light wires with telephone circuits on the same poles, the New England Telephone and Telegraph Co. recently requested the Malden Electric Co. to remove the electric wires on the telephone company's poles in Malden and Melrose The electric light company, instead of removing the wires, proceeded to place more of them on the poles. On the 5th, a number of these electric wires were removed by the telephone company in Melrose. This is a growing evil, and something will have to be done to satisfy telephone subscribers.

The electric railway absorbs the attention of the average Bostonian at the present time. The first trial trip of a car over the entire line from Oak square, Brighton, to Park square, was made on Monday night, the 31st of December, and the result was generally satisfactory. This branch of the West End Railway Co. employs the Sprague system. On Tuesday, January 1st., president Whitney and the directors of the West End street railway made a trip in one of the cars, and yesterday two of them were running most of the afternoon, carrying passengers the same as any other car of the company. The writer was one of those who tested the new conveyance yesterday, and he was, in common with all on the car, well pleased with the experiment. The line extends from Oak square, Brighton, through Washington and Cambridge streets to Allston, thence through Harvard street to Beacon street in Brookline, through Beacon street to West Chester park on the Back Bay, through West Chester park to Boylston, through Boylston to Church, through Church to Providence street, then to Park square and to Boylston street, and back through Boylston and the other streets. A branch line extends through Beacon street, Brookline, from its junction with Harvard street to Chestnut Hill reservoir. From Brighton to near the point on Beacon street where is the entrance to the Back Bay park, the overhead system of wires is used for the supply of motive power, but the rest of the way to Park square the conduit system is used. The conduit is located just outside of the track, so that where there is a double track both the conduits are between them.

On the 28th of December, Hon. Prentiss Cummings appeared before the railroad commissioners in behalf of the petition of the West End Street Railway Co., for authority to use the overhead electric system upon its line between Arlington and Bowdoin square, Boston via Cambridge. The electrical engineer of the company was also present, and said that either the overhead wire or the conduit system could be used without a particle of damage to man or beast. He said that the company would be ready within two weeks to run half-hourly trips of passenger cars propelled by electricity, between Brighton and Park square. When the men have become accustomed to the new motor, the trips will be made oftener. No one appeared in opposition to the road's petition, and it will undoubtedly be granted.

BOSTON, January 16, 1889.

CHICAGO.

The Chicago City Council Come to Terms with the Telephone Company.—A Bill Regulating Telephone Charges in the Illinois Legislature.—Chicago Electric Club Meetings; Discussion of Formulæ for the Insulation of Distributing Conductors.—The Postal Telegraph Co. Mulcted in Damages for Error in a Commercial Message.—Professor Barrett on the New City Lighting Plant.—Train Lighting on the Milwaukee and St. Paul R. R.—A New Dynamo by Mr. S. J. M. Bear.—An Interesting Installation of Accumulators.

THE city council found the solution of the telephone problem early in January. An ordinance was adopted which in its essential features was satisfactory to the aldermen and the telephone company. The measure is a compromise. The aldermen gave up the effort to secure a deduction of subscribers' rentals, and the company pays more for its privileges than it wished to do. The measure meets with general satisfaction. Chicagoans are tired of the squabble, especially those who have desired telephones but were unable to secure them, inasmuch as the company was not allowed to extend its wires. The ordinance has one feature which will tend to make it popular. It is understood that the $30,000 which the city will receive from the telephone company will be used in extending the electric light system. The principal conditions of the ordinance are contained in the following extract:—

Where the wires are laid underground the company shall, for the purpose of reaching and connecting their subscribers and branch offices, have the privilege of bringing the said wires, conductors, and cables to the surface within every four blocks and attaching the same to houses and carrying them over roofs, provided the consent is first obtained from the owner to whose property they propose to attach said wires, conductors and cables, and said wires shall be kept at least 12 feet above the surface of the roofs, except in such buildings as the wires are to enter, and said company may in so doing, cross streets, alleys, and city property with wires grouped in cables * * * It shall, through its president or secretary, file with the city controller, the first day of January and July of each year, a statement of its gross receipts from the telephone business done within the city of Chicago for the six months next preceding such statement, and the said company shall pay into the city treasury three per cent. on such gross receipts, and the company, during the term for which the ordinance is granted, shall not increase to its present or future subscribers the rates for telephone service now established. Also, that with the acceptance of the ordinance there shall be filed by the said company a schedule showing the rates charged for telephone service at the date of the passage of this ordinance within the limits of the city of Chicago.

* * * * * * *

Nothing in this ordinance contained shall be construed or taken as preventing the city of Chicago, whenever it shall be authorized so to do, from passing an ordinance regulating the rates to be charged by telephone companies for the rental of telephones, or for the licensing of telephone companies, it being the intention of this ordinance that the city of Chicago shall in no way surrender any rights it may have, or may hereafter acquire, to license telephone companies or to regulate the prices to be charged for telephones. But if the city shall acquire the right to regulate rates and exercise the same, the payment of the three per cent. shall cease.

There are provisions requiring the telephone company not to enter into combination with similar corporations under penalty of forfeiting its charter; also reserving the right of the city to grant franchises to competing companies. The duration of the ordinance is twenty years.

At the council meeting, January 7th, an attempt was made to reconsider the ordinance. Mayor Roche said he had signed the

ordinance believing that it was for the best interests of the city. The ordinance did not in any way interfere with the regulation of the telephone rates when the city had the requisite authority so to do. He said he favored $75 as a rate, but there was no way in which such a price could be secured at present. If the city refused to come to terms with the company it simply lost the three per cent. of the latter's gross revenue. The attempt to reconsider failed.

An ordinance has been introduced requesting the legislature to grant the council the authority to reduce the rate of telephone rentals. Fault has already been found with it. It has been asked why should its provisions be limited to the exercise of power over the telephone company; why should it not include all corporations operating under city franchises, such as gas companies and electric light companies.

Mr. O'Toole, of the town of Lake, has introduced a bill in the General Assembly, making the rentals of telephones in Illinois as follows:—When a subscriber has one telephone the rate shall be $3 per month; when he has two telephones, $2.50 per month. Between villages connected by telephone the charge shall be 15 cents for the first five minutes and five cents for each subsequent five minutes. The telephone company in Chicago could not stand any such deduction, and does not fear that the bill will become a law.

The Chicago Electric Club held the first meeting of the year, January 7th. Mr. F. S. Terry, the treasurer, presented his report, which showed the receipts of last year to be $2,644.83 and the expenditures $2,939.39. The deficit is fully covered by dues not paid in. Mr. W. A. Kreidler, the secretary, presented his report. He referred to the fact that the club had made a substantial gain in membership during the year and had been the means of laying before the electrical fraternity a highly interesting series of papers which had attracted attention not only in the United States but abroad. He spoke of the quarters now occupied by the club, and emphasized the necessity of securing rooms better adapted to the needs of the organization. The lease would expire he said in May, and the club after that time should have new quarters in which the cuisine especially would be of a more satisfactory kind. The club then listened to a discussion on the subject of insulation which had been brought before the meeting in this way:—C. C. Haskins, the city inspector of electric lights, invited representatives of the several electric light companies to meet and consider the subject of insulation. They responded, and at their meeting Mr. H. Ward Leonard proposed the following formula, to ascertain the requisite insulation on all circuits:—

$$\text{Insulation} = \frac{E \times 10{,}000}{C}.$$

These gentlemen without taking action turned the subject over to the club for its consideration. It was briefly considered at a meeting in December, and was set down as a special order for January 7th. At this meeting Professor Badt, who led in the discussion, proposed these formulæ for the determination of the necessary insulation:

$$\text{Direct current } R = \frac{E \times 25{,}000}{C}$$

$$\text{Arc system } R = \frac{E \times 1{,}000}{L}$$

$$\text{Alternating transformer } R = \frac{E \times 25{,}000}{C \times L}$$

where L = length of circuit.

These formulæ were discussed by Messrs. Cutter, Schillinglow, Thompson, and others. At the meeting of the club, January 14, the discussion of these formulæ was continued. Messrs. Leonard, Sperry, Thompson, Cutter, Sargent, Wilmerding, and others, spoke. After a two hours' session it was decided to adopt the second formula of Professor Badt, $R = \frac{E \times 1{,}000}{L}$ as the one to determine the resistance in all cases. A number of examples was worked out, and it seemed to be the general opinion that the results even in extreme cases were not unjust.

Judge Baker recently handed down a decision of considerable importance to telegraph companies. C. D. Lathrop & Co., secured some months ago a judgment against the Postal Telegraph & Cable Co. on account of errors in messages transmitted to New York over defendant's lines. The messages related to transactions in coffee. The attorney for the defendant asked for a new trial on the ground that the company was not liable for the errors because the printed heading on the telegraph message contained an exemption from liability; because Lathrop & Co. did not notify the company of the importance of the despatches, or of the damage likely to result from errors; and because the transactions of Lathrop & Co. were in the nature of gambling transactions. Judge Baker decided that, notwithstanding the printed exemption from liability on the despatch blanks, the telegraph company was bound to use ordinary care in the transmission of telegrams, and the fact of the errors raised a presumption of negligence. The messages being commercial messages the company had sufficient notice of their importance. As to the transactions being gambling transactions, the court said they were not necessarily illegal. Whether the purchases were legal depended on whether they were actual purchases, and the jury had decided they were. The court overruled the motion for a new trial, and entered judgment on the verdict for $6,698, the difference in prices of purchase and sale, resulting from the telegraph company's error. The telegraph company appealed.

Professor Barrett says the new electric light system in Chicago will prove highly economical. When the entire city is lighted by the better illuminant the saving from the displacement of gas lamps will aggregate, he estimates, about $250,000. His calculation is based on the saving from the displacement of 1,000 gas lamps by the arc lights already in operation. The 1,000 gas jets cost $26,000 annually. Estimating that four per cent. is paid as interest on the money invested in the plant, Professor Barrett says there will still be a yearly saving of about $9,000. The system is giving the greatest satisfaction, and the city electrical department is already overwhelmed with applications for the extension of the system. No trouble has been experienced with the underground mains.

The executive committee of the National Electric Light Association has leased a portion of the Exposition building in Chicago, for holding the February convention. The daily sessions will be held in one of the art rooms. A large amount of space will be reserved for exhibits.

The Chicago, Milwaukee & St. Paul Railroad Co. is now lighting two of its trains by electricity. The lights are supplied directly with current from the dynamo until midnight, when a battery of accumulators takes the load. The installation was made by Leonard & Izard.

Mr. S. J. M. Bear, a Chicago inventor, has written to a daily paper stating that he has designed a dynamo which will produce twice as much current per horse-power as any generator in use. He makes this statement in his article descriptive of the machine: "As more glow lamps are paralleled in circuit the applied power is lessened resulting in more light from less coal."

The Accumulator company, represented by Conant & Hood, Chicago, will make an interesting installation in the residence of Potter Palmer, on the Lake Shore drive. A 175-light United States dynamo operated by an Otto gas engine, will charge a set of accumulators for the supply of current for lamps in the house. The residence is wired for 250 lamps. When it is desired to light them all, the accumulators will supply half the lamps and the dynamo will furnish current directly for the balance of the lights.

CHICAGO, January 22, 1889.

MONTREAL.

New Contract of the Royal Electric Co. for Public Lighting; the Royal Company's Incandescent Business.—The Westinghouse Central Station of the Consumers' Gas Co., at Toronto.—An Edison Station Projected in the same City.—The Heisler Company also on the Ground.—Damage to Electric Service by Sleet, Gale and Fire.—Quick Restoration of the Quebec Telephone Service.—Electric Lighting Notes.

THE Royal Electric Co., notwithstanding public protests and counter proposals from other companies, have been awarded the contract for lighting Montreal, or rather an extension of time, and of the number of lamps to be used. As I have before stated, the Royal company's previous contract would have expired in two years. The new contract extends the period by three years—making it five years instead of two—and increases the number of lamps to 800 arcs, an increase of about 680 lamps. Montreal will thus be more generally lighted probably than any city of its size. A Mr. Fuller has, however, entered a suit to declare the Royal company's contract illegal, but nothing is expected to come of it.

The Royal company find orders for incandescent lights coming in much faster than they are able to install them, and are now 800 lights behind on order. Their new station will be in operation in a few days, from which all demands can be supplied.

The City of Toronto called for bids for an extension of the city lighting by 200 arc lamps Bids ranged as low as 24 cents. None of the tenders, however, were accepted, and the question of an increase in the city lighting is still an open one.

Toronto, however, is to be well supplied with incandescent lighting by the Consumers' Gas Co., who will use the Westinghouse company's system and sell light by meter. The plant as at present laid out will have a capacity of 3,000 lights, but will undoubtedly be increased very rapidly, as Toronto has no central station incandescent lighting at present. The Edison company have also organized a company there, planning for an ultimate station capacity of 5,000 lights.

The Heisler company have made strong efforts to establish a company in Toronto, but apparently without success as yet.

The vicinity of Toronto and as far east as Quebec was visited last week by a very severe sleet storm. The Bell telephone system, at Kingston, was completely demolished. The telegraph service of the Grand Trunk Railway in that vicinity was entirely down for several days. During the gale of the 10th inst., much

damage was done to lines and service. The Bell telephone exchange, at Quebec, was burned out on the 7th inst.; the fire is attributed to an electric light cross. New switch-boards were shipped from Montreal, and under the supervision of division manager McFarlane, work was rapidly carried on, so that by the time the damage caused by the sleet of the same night was repaired, the exchange was in working order, many of the subscribers not being aware of the fire damage.

The Royal Electric Co. report a sale of 30 arcs at Sherbrooke, and an increase of 20 arcs at Pillow, Hersey & Co.'s, Montreal. They will also supply 50 arcs at the ice palace during the carnival, and 31 arcs at the court house.

The Edison company report 600 lights in addition to their Toronto plant.

The Reliance company are to put in an arc plant at Prescott, Ont.

The Edison station at Sault St. Marie will soon be in operation.

The Chandivere Electric Light Co. (U. S. system), of Ottawa, have increased their station capacity 500 incandescents, making a capacity of 2,000 in all.

MONTREAL, January 20, 1889.

LITERATURE.

Practical Electrical Measurements. By J. SWINBURNE. London: H. Alabaster Gatehouse & Co.; New York: D. Van Nostrand, 1888.

ON the somewhat unusual assumption that needless accuracy has been the prevailing characteristic of previous treatises on electrical measurements Mr. Swinburne discusses in this volume what he terms workshop measurements as distinguished from more refined laboratory practice. It is mainly a reprint of articles that have appeared in the English *Electrical Review*, and after being revised and amplified they are now published as an attractive hand-book neatly bound in flexible covers. Whatever may be the general opinion regarding the practical utility of the apparatus and methods described in standard text books, such as Ayrton's and Stewart & Gee's, it is doubtful whether any experienced workman in the field of heavy electrical engineering, will complain that the measurements so far designed for this particular class of measurements are needlessly accurate, or that the tests ordinarily applied are amenable to any such criticism. The author comes to his task, however, so well equipped by practical experience, that there appears to be a basis for his very pronounced confidence. His selection and treatment of the subject-matter is decidedly original, and a large amount of stereotyped matter, which is usually deemed indispensable to works on electrical subjects, is conspicuous by its absence. It is a source of regret, however, that, notwithstanding his somewhat didactic style, the author often unwisely assumes so much knowledge of the subject in hand, on the part of the reader, that essential detail is frequently omitted. This is particularly noticeable in the treatment of dynamos and motors.

The opening chapter discusses the measurement of resistance, and describes several modifications and practical forms of the Kirchhoff and Thomson bridges for the measurement of very small resistances, such as armatures. The much felt want of a cheap and yet approximately accurate Wheatstone bridge is strongly expressed, and ought to merit the attention of instrument manufacturers. The measurement of leaks—a somewhat neglected subject—is considered at length, and the use of ohmmeters discussed. It is difficult to tell just what the author's opinion of the latter instruments is, but he evidently thinks they ought to be calibrated throughout their scale. He also holds the same view, apparently, regarding all the meters—either for current, potential or energy—which he afterwards describes, and, doubtless, most of the users of such instruments will agree with him. This is in fact, a serious reflection on the character of the commercial test instruments now produced, for it must be obvious that almost any combination of iron and copper will produce an effective instrument with an arbitrary scale, and it ought to be equally obvious that the real requirements for an electrical measuring instrument are that it shall be direct reading and have a scale of uniform divisions.

The greater part of the remainder of the book is devoted to a description of many of the numerous modern instruments designed for the measurement of electrical quantities, and of various methods of standardizing them. The defects peculiar to the different instruments are pointed out with considerable minuteness, and a multitude of corrections for temperature, contacts, etc., are treated as of grave importance. Most of the simple methods described are considered inaccurate, and in short the author's critical tendency is so pronounced, that the reader is inclined to the opinion that he is not so opposed to needless accuracy as he imagines.

Mr. Swinburne appears to have a *penchant* for measuring all electrical quantities by means of the fall of potential along wires of known resistance. All sorts and sizes of resistance boxes adapted to this object, including a number of "ohm" and "mho" switches for combining the wires, are described in detail. Of course potentiometer tests can be made accurately if sufficient care is observed, and they are often the most convenient, but to assume that they are particularly adapted to workshop calibrations of ammeters and voltmeters, is easier than to prove. For reliable work they are essentially laboratory methods as they involve the use of accurately adjusted resistances and standard cells, both of which are subject to temperature corrections, and of at least two sensitive galvanometers. It is doubtful if any person of experience who should be required to calibrate a large number of instruments, would apply the method to any other purpose than that of standardizing a standard instrument.

Although the author claims, in the preface to this work, to have selected for description only such instruments as are best suited for commercial use on account of their approximate accuracy combined with portability and cheapness, he describes such apparatus as Sir William Thomson's new gravity instruments, which are known to require the most delicate manipulation of any yet devised. He also refers to the Forbes's meter and the Ayrton & Perry bicycle wheel voltmeter, neither of which have ever been placed on the market. The employment of storage batteries as the source of current for calibration work is strongly recommended, and several convenient switches for transposing them when applied to this purpose are described. Standard cells and voltameters as applicable to calibrations are adequately discussed, and there are two instructive chapters on the respective subjects of meters and the winding of voltmeters. The portions of the work relating to dynamos, batteries and incandescent lamps are, however, merely discursive and lack detail and preciseness. This seems to be rather unfortunate, for after spending so much time in learning how to standardize instruments, the student would like to be taught how to use them. To persons more or less experienced these chapters will not be without interest, as the author criticises some prevailing notions in a pungent and effective style.

The concluding chapter on alternating currents, while not lacking in information, is written in a style hardly consistent with the character of the book. It is a rambling discussion of the subject, suggesting various practical tests, but not describing them with sufficient fullness to enable those unfamiliar with the subject to apply them. The work is original, useful, but incomplete.

Die Erzeugung und Verteilung der Electricität in Zentral-Stationen. Von Dr. MARTIN KRIEG. Band ii. Die Erzeugung und Verteilung der Electricität durch Gleichstrom-Maschinen mit und ohne Verbindung von Akkumulatoren. Magdesburg, 1888. A. & R. Faber.

THE numerous types of dynamos already in use and the innumerable modifications constantly introduced in the apparatus of central stations, render it impossible for any author in the limits of a readable book to describe fully the equipment of even the most important electrical plants at the date of his writing. The sudden demand for all kinds of electric lighting apparatus that has grown up since the establishment of the Edison lighting station in New York (1882), has called into being many ephemeral systems for supplying plants. The market just now is filled with machines and mechanisms whose value has not received any adequate test. Meanwhile, a process of selection is going on which will result in the "survival of the fittest." To attempt for some years a complete description of all the machines and kinds of plants in successful operation would be a premature undertaking. Anything, however, which assists in classifying knowledge regarding what is in use and thus promoting the selection of the "fittest," is valuable. The book under notice is calculated, in this way, to aid materially in the evolution of the ideal central station.

If the first volume (on the Generation and Distribution of Electricity by Alternate Current Machines and Converters, which has not yet come under our inspection) be as suggestive as the second, it is well worth reading. The author's aim is to impart information and not to educate. He realizes the embarrassment to which the existence of numerous systems exposes him, and he wisely confines himself to a detailed description of a few of the more important. In the nine chapters, into which he divides the 375 pages, he discusses in the first four, prominent types of machines and accumulators, and systems of distribution and regulation. The rest of the book is given up to descriptions of methods of installation, disposition of conductors, description of certain central stations, and calculations of the cost and profit of central stations.

The machines described in the first chapter were chosen with judgment. The descriptions, aided in most cases by excellent illustrations, are concise yet simple. The power required and volt-amperes furnished are indicated in tabular form. The chapters on accumulators is rather more complete. This might be expected for two reasons: first, our information regarding accumulators has been rather meagre; and, second, the bias of

the author is, apparently, for the more extended use of accumulator in central stations. Indeed, it may be said that the tendency of the book is in that direction. It should be added that this position is well maintained. Dr. Krieg's arguments for the use of accumulators on the ground of economy and convenience will be hard to meet.

A good indication of the fact that methods of constructing more economical and convenient secondary batteries are receiving close attention and with some degree of success, is the secrecy which certain establishments maintain regarding their processes. The author mentions this secrecy to account for his lack of detail in some cases. Statistics are given of the accumulators of the Electrical Power Storage Co., the Julien system, the de Khotinsky, Fasbaky-Schenck, and Tudor. The Tudor batteries were used by Dr. Kohlrausch in the experiments on which were based the conclusions regarding accumulators, an abstract of which was published in the ELECTRICAL ENGINEER, for November, 1888, and which are given in this book.

Dr. Krieg's treatment of conductors and auxiliary apparatus is marked by the conciseness already noted, which is, nevertheless, not inconsistent with completeness. He devotes considerable space to various systems of underground cables, making his descriptions quite exhaustive.

The chapters on the building and economical operation of a central station are methods of computation, and are the best in the book. It is unfortunate that such good text as that of this chapter should be spoiled by muddy cuts. There is no reason why the curves so elaborately worked out should not be presented to the reader in a form easier of interpretation. The estimates for the cost of construction and maintenance of an electrical plant are carefully made, and form the basis of the recommendation for a more extended use of accumulators. The fact that the larger the plant (within limits) the less is the cost per lamp, is well brought out in the last table of estimates given. In the last chapter, on methods of computation, several of the curves are very ingenious, and afford a simple method of computation. The descriptions, in the eighth chapter, of the large central stations are interesting if not important.

The book is a useful one, and we bespeak for it the cordial reception desired by the author. The good judgment shown in the selection of material and in the author's views, dispose the reader to give attention and consideration to suggestions which may at first seem unusual or even questionable.

NEW PERIODICALS.

Electric Power. Conducted by RALPH W. POPE and GEORGE H. STOCKBRIDGE. HENRY W. POPE, Business Manager. Published monthly by the Electric Power Publishing Company, 150 Broadway, New York.

We have received the first number of this journal, dated January, 1889. As its title implies the publication will be devoted chiefly to the interests of the transmission of power by electricity. In their announcement the editors say: "It is the purpose of this journal to assist in bringing to public attention the manifold advantages of electric power."

Readers of the ELECTRICAL ENGINEER will recall Mr. Ralph W. Pope's connection with this journal under its former title—THE ELECTRICIAN AND ELECTRICAL ENGINEER—as one of its editors, with pleasant reminiscences of his broad views and genial wit; while Mr. Stockbridge's former association with the *Electrical World*, in charge of its patent bureau, is fresh in the minds of all who keep up acquaintance with electrical publications.

The initial number of *Electric Power* may doubtless be taken as a fair example of its scope and quality, and in both respects it fully deserves attention in electrical circles, as well as from all who are interested in industrial pursuits. Besides important original articles by David E. Lain, Thos. D. Lockwood, G. R. Blodgett and S. D. Greene, it contains many well-chosen selections and abstracts, together with a large number of technical and industrial notes, bearing chiefly upon the electric motor and its uses.

The journal is a quarto of twenty-four pages, exclusive of advertisements, and we are restrained from a warm commendation of its make-up and general appearance only by its resemblance to THE ELECTRICAL ENGINEER in those respects. We can hardly appropriate to ourselves the flattery of imitation in this instance, inasmuch as the best features of our journal are due in large measure to the intelligent work devoted to it some years ago by one of the editors of the present new journal.

The Telephone. A Review of Electrical Science. Published Fortnightly. London: 18 Charing Cross.

"The space of our paper will to a great extent be devoted to telephonic intelligence and to improvements and inventions connected with the Telephone."

The above quotation is from the editorial announcement found in No. 1, vol. 1, of the new electrical journal just started in London. The editors say further: "The attention which we propose bestowing upon this subject will, however, not be an exclusive one, and part of the paper, and a part to which we attach the utmost importance, will be reserved for original articles on Electrical Science, both theoretical and practical, * * *."

This periodical begins its career with an issue which is not only very readable by all interested in electricity, but must prove of special interest in telephone circles. It contains technical, practical and statistical articles relating to the telephone, and a fair amount of other matter touching theoretical and applied electricity generally. We shall look with much interest for the succeeding numbers of *The Telephone.*

NEWS AND NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF JANUARY 8th, 1889.

The January meeting of the Institute of Electrical Engineers was held at the College of the City of New York, at 8 P. M.

On motion of Mr. T. C. Martin, Mr. Francis W. Jones was elected chairman for the meeting.

There being no routine business before the meeting, the chairman immediately presented Mr. E. G. Acheson, who read his paper on "Lightning Arresters and the Photographic Study of Self-Induction." (See page 47.)

The Chairman—Gentlemen, you have before you a very interesting subject. It is unnecessary for me to say how well and ably it has been placed before you. The paper is now before you for discussion. It is suggested that I call upon Dr. Moses.

Dr. Otto A. Moses—As I have had a very good opportunity of knowing the careful methods in which Mr. Acheson directs his thought experimentally, I feel to a certain extent diffident upon being called upon so suddenly to express any doubts as to the correctness of his experiments. He has conferred with me occasionally on the subject in the course of his experiments. There are one or two things that might tend to start this discussion which I will suggest, so that some who are present here who I know have taken great interest in this matter may continue it. If Mr. Acheson will look at figure 2 (page—) in these various experiments with the Leyden jar, he will remark where he has a wire coiled around the metallic coating of the conductor, he has substituted there a supplementary coil of two or three turns, and has brought the terminal of it to a certain distance from the interior conductor. He has done that, as I understand, as a substitute for the wire W, in both cases making the air space the same. Will Mr. Acheson please repeat what was the object of that substitution so that I may direct another question afterwards?

Mr. Acheson—The doctor is mistaken in regard to its being the equivalent of the wire W. In order to ground it I have assumed that the outer surface of the jar J represents the earth, and I connect the outer surface of the lead to that by a short metallic connection, in order to reduce it to one potential as we would have it in practice.

Dr. Moses—Were the lengths equal of the two wires—the one wrapped around the lead coating and the wire W?

Mr. Acheson—No, sir. And the coil of the wire E about the lead in this case was probably accidental in the sketch, because in reality it was only one turn around it, so that there was no parallel effect there.

Dr. Moses—There was another point that I would like to be enlightened upon. You mention in one case that you experimented with copper and iron wire and used wires of the same diameter in both cases. Did you take into consideration at all the conductivity of the wires, or did you think that unimportant?

Mr. Acheson—Owing to the existence of that air space I assumed it was wholly useless to consider the resistance of the wire, as we had an infinite resistance already in the circuit; I mean in the space A.

Dr. Moses—In that space A did you consider the difference in the size of the condensing surfaces of N and A?

Mr. Acheson—Yes; I attempted to make a measurement of the capacity of the apparatus with the jar removed; but although I had a constant on the galvanometer—a very high constant—I failed to get any capacity, not because there was none there, for we knew that there was, but it was beyond the reach of my instruments. The size of the balls was considered of course, and the ball X was made of a size that would allow me to obtain a sufficiently high electromotive force without spinning off, as it would do where it was very small.

Dr. Moses—By what means did you cause your rotations?

Mr. Acheson—By hand. I used in fact Mrs. Acheson's sewing machine as the motive power.

Dr. Moses—In photograph No. 13 (page 53), when you shifted the machine——

Mr. Acheson—I shifted the position of the plate—the sensitive plate, my revolving disc remaining in its former position. The

disc being here rotating, immediately back of it was my sensitive plate, and in order to produce this first spot marked 1 I had the plate at a certain height and raised it higher for the succeeding ones twice.

Dr. Moses—Perhaps these experiments may have a bearing on the sparking in the brushes of dynamo machines?

Your power there of avoiding the spark might enable you to avoid the spark on the brush, which comes evidently from the same cause. In the paper in which Professor Hughes described these experiments to which you refer he indicated that there might be some difference in the metals that were used for brushes. There had been experiments in this country before then in that direction; but it seems to me it would be quite a prolific field of investigation to find out whether by alternating brushes, perhaps of iron and copper, you might not be able to eliminate the spark from the dynamo machine.

Mr. E. T. Birdsall—Dr. Moses speaks of sparking from the brushes of dynamos. It has been some time since we have seen much of that.

The Chairman—We have with us a gentleman from Boston, Mr. Hamilton, from whom we should be pleased to hear.

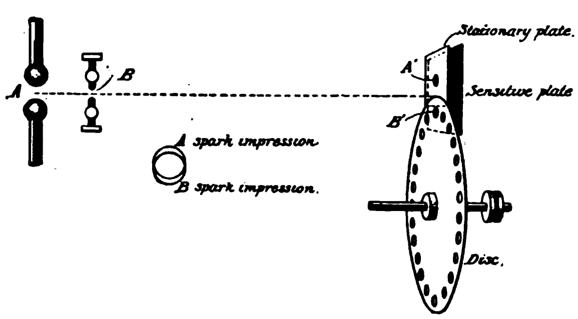
Mr. Leonidas Le Cenci Hamilton—I have been very much pleased to hear the paper which has been read. One question arises in my mind—whether or not the ghost, so-called, in the photograph might not have been caused by a difference in the revolution of that disc. It seems to me that the experiments, with no possibility, as I can understand it, of accuracy, as to velocity of revolution, might possibly result in this ghost filling the plate.

Mr. Acheson—I neglected to state the manner in which the disc was timed. I timed it always. Of course, I could not get an exact speed. These are not printed exactly like the negatives. While some of them exhibited a little or no ghost at all, others exhibited a length of as much as a tenth of an inch. Now, we know there is no difference in speed like that.

Mr. Hamilton—How did you control the speed?

Mr. Acheson—I had everything ready for the discharge of the jar and held that in waiting until I had the speed up, with my watch before me. I worked with a treadle so that I had perfect control of it and worked it up until I had a revolution of the band wheel of a certain value, of which my note book gives the record in each and every experiment.

Mr. Hamilton—The photographs were each separate, were they not? For instance, in No. 5 (page 53), A and B, were the photographs taken at different times?



MR. ACHESON'S APPARATUS.

Mr. Acheson—That A, B spot was made by one spark at the same instant of time. The spot A was produced through a stationary aperture, while the spot B was produced through the moving aperture in the disc. It was a question that I wanted to decide whether any vibration that might be introduced in the work would cause any movement of the outlines, and I always had the A spot for that object, so that I might have a means of comparison with the spot produced by the moving aperture. I am sorry that these are not an exact print of the negatives, but I presume we never will have them. I do not suppose that they could be reproduced exactly. Even if the plate is good the printing will disfigure it.

Mr. L. W. Serrell, Jr.—I would like to ask Mr. Acheson if he developed the negatives all at the same time, that is, with the same developer, and gave them all an equal length of time in developing. This ghost or tail of a comet is a vanishing thing, and if the development was applied at different lengths of time it would make a different depth to the negative and make a different length to the ghost or to the tail. I would like to know whether they were all developed at the same time.

Mr. Acheson—I am not a photographer by profession, and, in fact, I never did any photographing until I commenced this work. I bought my supplies in a store and used a small hand-book as a guide. Although I spoiled some plates, each and every one of them was developed separately, and it was all done after night. None of this work was done by daylight. Much of it was done in the neighborhood of midnight or later, and, as a rule, after considerable experience, I developed them until they ceased to show any increase.

Mr. Birdsall—In taking pictures on glass plates such as Mr. Atcheson took, although these probably do not exhibit that defect to any extent, a glass sensitive plate pointed at any bright object, and a picture taken of the bright object, it will always exhibit this halo, and taking a picture through a hole like that, if the source of light were not perpendicular to the surface of the plate, it would exhibit that halo on one side. If the spark was not far enough away from the surface of the plate, so that both the holes A and B were practically in a perpendicular line, that property which is called halation of plates, and which is avoided in the paper negatives—that property would introduce probably an appreciable error, as in taking pictures with say a 10-inch focus lens, we get a picture of the sun on a plate about one-quarter of an inch in diameter, and there will often be a half-inch of this halo around this image on the plate. If we take a picture of the sun through a large hole it would in all probability show more halation on one side than on the other, similar to these pictures, although that error may not be introduced in these.

Mr. Joseph Wetzler—There is one point that occurs to me in connection with figure 5 (page 52). Mr. Acheson remarked that when he applied an iron rod in that coil the spark was very much diminished. He attributed this at first to the magnetization, but when he inserted the copper he found the same diminution of spark. He then came to the conclusion that the retardation was due to the energy abstracted from the circuit by electric currents set up within the bar. It seems to me that that result of the equal action of the iron and the copper might have been predicted when we consider that it takes some time for iron to magnetize; in other words, the iron would not, as a rule, magnetize with a current of a static discharge on account of its great rapidity; that static discharge is practically instantaneous; while it takes some time for iron to magnetize, something in the neighborhood of one-hundredth of a second, if I remember rightly. We might, therefore, conclude that the effect was not due to magnetization of the iron, but was probably due to electric currents set up in the iron.

Mr. Acheson—I quite agree with Mr. Wetzler in his opinions; it is such as I finally formed.

Mr. Serrell brought up a question in regard to the production of the ghosts being due to the line of the ray of light not being perpendicular to the glass surface. At first I had some difficulty and thought I had achieved success before I had, owing to the fact that my two sparks and the hole through which they were taken were not in a direct line, and it caused a distinct overlapping of the outlines of the spark as produced in the spot, very distinct and sharp. At first I thought it was a difference of time between the two sparks; that the spark was a little back of A, which was what I wanted, and I was much pleased; but it was not the case; it was simply due to the fact that they were not in line.

Professor Geyer—I was unfortunate in not hearing the whole of this paper, and I am not sure that I fully grasped it. I hope I may be pardoned in asking a question for my own information—to what cause, Mr. Acheson, did you ascribe the ghost? I am not sure that I quite caught that.

Mr. Acheson—It is due to the oscillation of the current and the continuous charging and discharging of the condenser surfaces, which has to go through the space A, as illustrated in these figures, producing a spark continually diminishing in flow, and continuing for a certain length of time until the energy is expended in some manner. On the negatives you can see that the spark weakens and fades away until it actually disappears. You cannot give it a definite length. You cannot set an end to it. This is due to that gradual diminishing of the amount of energy which is oscillating backward and forward in the circuit.

Professor Geyer—I know of an analogous experiment which I think proves that the position you take is perfectly correct, and that it is not necessary to find photographic causes for the ghost. The experiment, I recollect, was one made by Professor Meyer, of the Stevens Institute, where a Leyden jar was discharged through the prongs of a tuning fork, at the end of which there was a little pointer which moved over a rotating cylinder blackened with lamp black. When the Leyden jar was discharged there was made on that blackened paper one great blotch where the lamp black was dissipated. At some distance further on, the cylinder rotating with uniform velocity, there was another blotch, and then there were three and four, and then there would be a moderate interval; then there would come a great group of them, and then another group, so that, taking the trouble to count them, there were actually several hundred of those discharges recorded, with no possibility of any photographic disturbance on this cylinder, showing that there were at least 700 of these oscillatory discharges.

Mr. Charles Cuttriss—I would like to ask Mr. Acheson a question in regard to these diagrams as taken from the negative. You will observe in both of them that there is a full light circle and then a tail. Now, I would ask if that was so on the photograph, or was it not a gradual broadening up without any abrupt line between the bright part and the other? It would appear to me as though there was at the first discharge a greater volume of light or a more intense passage of current just at that distance to photograph the true hole and show it across the table.

Mr. Acheson—If I understand the gentleman correctly he wants to know whether the outline of the aperture in the disc is clearly defined. It is, if that is the question. On the negatives it is clearly defined. You can trace perfectly all those outlines. I think that you are correct in assuming that the first discharge is vastly greater than any succeeding one. That outline is shown on the negative.

Mr. Allan V. Garratt—I have listened with a great deal of interest to this paper and discussion, and I cannot help wishing that before we go away we may get a few more facts in regard to these photographs, if possible, to clear up any possible doubt as to their character. I should like to ask Mr. Acheson if the plates were all of one make and of the same number?

Mr. Acheson—All of same make and all number 26.

Mr. Garratt—I understand they were developed, practically, until they would not develop any more. I have occasionally played with plates myself. I see no reason under those circumstances to suppose that the trail of light, which I think a photographer would not call a ghost, is not correct. I do not see any elements of error there. In regard to the speed of rotation, some of the trails are only half the length of the others. I do not know with what degree of regularity Mr. Acheson can revolve a sewing-machine wheel, but I should suppose that he would be able to eliminate an error of fifty per cent.; that is, if he worked it as hard as he could, and if he was in equally vigorous condition during all of his experiments, I see no reason to suppose that any considerable degree of error was introduced there.

I cannot help feeling, gentlemen, that this paper—the matter therein contained—is something that will lead to a good deal of discussion and investigation on this extremely interesting subject. I believe that it is one that we shall hear a good more of.

Mr. Birdsall—My suggestion in regard to the spot of lights showing the entire circle of the hole and then fading away, is that the first spark of the continued series of sparks which formed the discharge, might be the one which has the most energy in it in the form of light due to conditions of the air, such as burning the dust between the poles or anything like that, and the succeeding ones might have as much energy in them, although not so much of that energy in the form of light, but more in the form of heat.

Mr. Serrell—I would like to ask Mr. Acheson which way his wheel turned around, whether the tail was due to the wheel, gradually cutting off the light on the plate, and the spark being produced by duration, or whether the first bright spot was due to the first flash, and the wheel went in the direction of the tail.

Mr. Acheson—The aperture moved in the same direction in which the tail faded.

The Chairman—This certainly is a subject of interest in almost all branches of the electrical profession, particularly in the department with which I have been identified myself, where we find these antagonistic currents in our relays, in our cables and in our wires. It causes us a good deal of trouble to find just how they act and also to overcome their bad effects; particularly in relays where the signaling current passing through the various convolutions arouses this antagonistic current and causes relays to act very slowly. It changes the character of the signals entirely. I think probably, as suggested, in dynamo machines, this current has a great deal to do with almost every electrical apparatus. I do not see how you can avoid it.

If there are no further remarks to be made upon the subject the secretary has some matters which he wishes to bring to your attention.

The Secretary—Gentlemen, it gives me pleasure to announce that the next paper to be read before the Institute in the regular series will be by Lieutenant Jarvis Patten, a member of the Institute, on February 12th, entitled "On a New System of Multiplex Telegraphy," with illustrations. It is possible that during the present month an extra paper will be presented by Mr. F. L. Pope, on some recent work in the field of electro-metallurgy. He is engaged in the preparation of this paper now, but he is not certain about the time at his disposal, and it is barely possible that he may not have it in readiness, this month, but if it should be ready due notice will be given as usual.

Mr. Cuttriss—If the discussion on this paper is ended I would take pleasure in moving a vote of thanks to the author for one of the most able papers and showing the deepest insight, I think, into recent research, that we have had before us.

The motion was carried.

The Chairman—I have, therefore, very much pleasure in presenting Mr. Acheson with the unanimous thanks of the Institute for the able and interesting paper he has presented with so much pains and so much care and accuracy of experiment.

Mr. Acheson—I thank the Institute for this kindness in appreciating a little work.

Adjournment.

.... ANOTHER INDUCTIVE TELEGRAPH INVENTOR.—Rev. Balus Cade, of Wake Forest, North Carolina, has a device by which a telegram can be sent from a *morning* train, or from one *morning* train to another.—*Electrical Review*, N. Y. Why not from afternoon trains?

THE EDISON UP-TOWN STATIONS.—NEW YORK.

The beginning of service by the Edison Illuminating Company in the up-town districts of New York is a very noteworthy event in the progress of house-to-house electric lighting. It is of special interest, not only on account of the magnitude of the undertaking, but equally or more so from the thorough and magnificent manner in which the whole work has been designed and carried out.

After an investigation of the lighting in New York city, it was decided to lay out and construct generating stations and conductors for distribution of current, to supply the territory bounded by Seventeenth and Fifty-ninth streets and Third and Eighth avenues. The supply of motor service from the same stations and through the same conductors is included in the system. In addition to the two stations now substantially completed in 26th and 39th streets, a third in 53d street will soon be under construction. The station buildings are most substantial in construction and very elegant in appearance. In their interior plans they present striking novelties, the distribution of the machinery, boilers and engines, having been laid out on altogether new lines.

The Twenty-sixth street has a frontage of 56 feet and a depth of 98 feet 9 inches. The excavation for the foundations, cut out of solid rock, has a depth of fourteen feet below the street. The height of the building is about 90 feet. The two stations are substantially alike. There are a basement and four stories. In the basement the engines are located; on the first floor the dynamos; on the second floor, apparatus for handling ashes, and a general workshop; and on the third floor the boilers. The top floor is devoted to the storage of coal, tanks for water supply, and a commodious meter room.

The engine room contains 14 Armington and Sims' high-speed engines of 200 h. p., each belted to two dynamos on the next floor above. The 28 dynamos have each a capacity of 600 amperes and an initial E. M. F. of 140 volts. On the second floor a central space is fitted up as a general workshop and repair room. On each side of this space, next to the wall, are located the large horizontal smoke flues leading from the boilers above and extending along each side of the building to the rear and connecting with the smoke stacks. Between the smoke flues and the partition dividing off the workshop are the ash pits and the cars for handling ashes.

The Babcock & Wilcox water tube boilers are arranged in two batteries of seven on each side of the third floor.

A striking feature in the carefully worked out plans of the station house, is found in the arrangements for storing and handling coal. There are two large elevator shafts from the basement up to the roof. The elevators are balanced against each other, their cables winding and unwinding on the same drum, and operated by a double cylinder engine of ample capacity located in the basement. For each of the platforms there is an iron car capable of holding 1¼ tons of coal. Supported about midway between the floor and ceiling of the coal loft on the fourth floor are three car tracks, to the level of which the coal is hoisted in the car. When the load of coal arrives at the top of the elevator shaft, the car is shoved off on a weighing platform. The car is dumped by automatic apparatus at any point desired. In the meantime the other elevator with its empty car has descended and is receiving its load. Messrs. Crane Brothers supplied the elevators. Coal, from the loft, is delivered in front of the boilers through iron chutes.

Two large and one smaller Davidson pumps are placed in the vault under the basement.

The entire scheme of the up-town stations and service was carefully elaborated, with the view of employing the most advanced and best electrical and engineering methods of design and construction, by a special committee. The committee comprised Mr. E. H. Johnson, president of the Edison Electric Light Company; Mr. C. H. Coster, director of the Edison Electric Lght Company and of the Edison Electric Illuminating Company; Mr. John I. Beggs, vice-president and general manager of the Edison Electric Illuminating Company, of New York; Mr. C. E. Chinnock, the former general superintendent of the Edison Electric Illuminating Company, of New York. Mr. J. H. Vail, the general superintendent of the Edison Electric Light Company, was appointed chief engineer of the committee. Mr. Chas. E. Emory, M. E., was retained as consulting engineer, and Mr. Albert Buchman as the architect.

The result of their work as seen in the two solid, elegant and thoroughly equipped stations, testifies to the skill and good judgment of the committee, no less than to the broad and liberal views of the directors of the Edison Electric Illuminating Co. evinced in their large investment of capital in the work.

The distribution is to be by the three-wire system in the up-town district. About sixty miles of the well-known Edison tubes have already been laid underground in the up-town streets—making about 180 miles of conductors.

.... THREE classes of men have been required for the accomplishment of the greater triumphs of science; the investigators or discoverers of abstract and often apparently useless truths, teachers of all grades, and popularizers.—*Alpheus Hyatt.*

A RESTLESS PHILANTHROPIST.

We have been favored with a circular letter, reprinted below, by one of the fortunate recipients. It is rather too good to keep and will be sufficiently diverting without comment.

Designer of Apparatus for Special Purposes.
Contractor for Arc and Incandescent
Electric Lights and Steam-Power.

City Street Lights Tested and Compared with
Contract Requirements,
Complete Plants Erected for City Lighting.

HAROLD P. BROWN,
ELECTRICAL ENGINEER,
201 West 54th St., New York.

Dear Sir:—I address you on a matter of LIFE and DEATH which may personally concern you at any moment. Last spring alarmed at the large number of deaths caused by careless methods and criminal economy on the part of many electric lighting companies, I started a movement in favor of greater care for public safety. In a careful essay I tried to point out the sources of danger and to indicate means whereby arc lighting could be made safe. But there is no possible way of making safe the high-tension alternating current, which is now extensively used for incandescent lighting. At once representatives of the alternating current syndicates, which are both wealthy and unscrupulous, made vicious personal attacks upon me and put themselves upon record as claiming that their current was "absolutely harmless" and "perfectly safe" (see *Electrical World*, July 28). The only course open to me to maintain reputation was to demonstrate by experiment the exact death pressure in the continuous and the alternating currents; but to do this with scientific accuracy required apparatus which cannot be obtained at short notice in this country.

I therefore called upon MR. THOS. A. EDISON, whom I had never before met, and asked the loan of instruments for the purpose, which could not be obtained by me elsewhere. To my surprise Mr. Edison at once invited me to make the experiments at his private laboratory and placed all necessary apparatus at my disposal. The results proved beyond question that the alternating current would PRODUCE INSTANT DEATH at one-sixth the pressure used by the alternating current companies for electric lighting and pronounced by them "perfectly safe." (See inclosed report, Medico-Legal Society.)

Under the auspices of Dr. Cyrus Edson, of the BOARD OF HEALTH, I then made two public demonstrations at the School of Mines, Columbia College, which the alternating current people were invited to attend and were given opportunity to verify my measurements with their own instruments. This, of course, they failed to do, and in spite of the fact that their current has *killed and crippled for life* a large number of men, they still endeavored to deceive the public, objecting to my experiments because the subjects used "weighed less than a man and were therefore more easily killed." I then invited the committee of the Medico-Legal Society having in charge the determination of the BEST METHOD OF EXECUTING CONDEMNED CRIMINALS (under the N. Y. electrical execution law which goes into effect Jan. 1, 1889), to witness the killing, with the alternating current, of animals weighing as much or more than a man. This so impressed the committee with the death-dealing qualities of the alternating current that they drew up the inclosed report, recommending its adoption for EXECUTION PURPOSES at exactly the pressure used for "safe and harmless" electric lighting. At the society's meeting of Dec. 12, this report was *unanimously adopted* after the representatives of the alternating current companies had been given ample opportunity to defend their views.

Even this did not discomfit them, for Mr. Geo. Westinghouse, Jr., president of one of the alternating current companies, published on the 13th a letter upholding his high-tension alternating current as "less dangerous than the continuous." To test his sincerity in making so absurd a statement, I published on Dec. 18th the enclosed challenge which will explain itself. This has as yet received no acceptance.

Now, HOW DOES THIS AFFECT YOU? The special danger in the use of the high-tension alternating current lies in the fact that its physical effect on the nerves is many times greater than the continuous current with the same pressure, and the rapid alternations place the insulation of its conductors under a tremendous strain, similar in effect to that produced by what is known as "water hammer" in pipes. This strain causes *leakage to the ground* from the wires which I find upon careful measurement, is sufficient to kill or cripple any person standing on a damp place and touching either wire, and the danger increases in direct proportion to the length of the wire and the dampness of the day. That this danger is not imaginary is shown by over 15 deaths and a large number of serious injuries within the past year from this very cause, and many of these cases were *not* electric light employés. In every city having a large alternating current station many crippled pensioners can be found. The most serious cases of injury are those of a son of Professor Young, of Princeton College, who was paralyzed by stepping on a ground connection while touching an alternating current wire; and W. J. Bell, of St. Paul, whose nervous system was completely shattered by touching a guy wire on a District telegraph pole which happened to be in contact with a Westinghouse alternating current wire some distance away. In this case, the "insulation" of the alternating current wire was *apparently perfect*. It is not an uncommon thing for telephone and district telegraph apparatus to be burned by their wires coming in contact with the alternating current conductors; any person who then touches the telephone or call box runs a terrible risk. This BRINGS THE DANGER HOME TO ALL OF US.

What is the remedy? Simply a limitation of the pressure to 300 volts or less, which will then make the alternating current no more dangerous to the general public than the arc light wires, since in order to kill it would be necessary to grasp both wires. The leakage to ground would then be less than the pressure required to kill. The expense occasioned to the electric lighting companies by this reduction of pressure to SAFE LIMITS would be simply the cost of about *twice as much additional wire* as they now have in use, which would be insignificant in comparison with the good result thus obtained.

I therefore ask you as a public-spirited man, to oppose with all means in your power the extending of the high-tension alternating system in any city or town where you have influence; to lend me your aid in securing legislation which will keep this EXECUTIONER'S CURRENT out of our homes and streets, and prevent reckless corporations from saving their money AT THE EXPENSE OF THE LIVES OF THOSE DEAR TO YOU.

The killing of a little child in the streets of Philadelphia, on Dec. 17th, outweighs all possible considerations of "economy in first cost" so temptingly set forth by Mr. Westinghouse's company and others. I shall be glad at any time to send you printed matter on this subject or to *assist you in any way* against the encroachments of the executioner's current. In return I shall esteem it a favor to receive information of any deaths or injuries from electric lighting in your vicinity, or any "answers" to my arguments brought forward by my opponents.

Sincerely yours,
HAROLD P. BROWN.

ENGLISH COMMENT ON MR. BROWN.

The conflict between the continuous and the alternating systems has been renewed with increased vigor in the states. In a long letter to the New York *Times*, Mr. George Westinghouse, Jr., makes some sharp comments on the recent experiments of Mr. Harold P. Brown, at Edison's laboratory, Orange, N. J.; asserting that Mr. Harold P. Brown is not seeking for truth, but is looking after the imperiled interests of the Edison company. Mr. Westinghouse is not content that the alternating current system should be considered as safe as its rival, it is much safer; "the alternating current is less dangerous to life, from the fact that the momentary reversal of direction prevents decomposition of the tissues." To this onslaught, Mr. Harold P. Brown has replied by a challenge to a duel *à l'outrance*. Mr. Westinghouse is to take a current alternating 300 times a second through his body, and Mr. Brown will do likewise with a continuous current; the pressure is to begin at 100 volts and increase by 50 volts at a time; each contact is to be made for five seconds, and the battle is to go on until one or the other has cried enough. All this is, no doubt, excellent fooling, but has little or nothing to do with the question at issue, which is simply whether the dangers of high tension currents are so great and of such a nature as to warrant the enforcing of precautions which would practically amount to prohibition. This question, we take it, is satisfactorily answered by our own experience of alternating current distribution from the Grosvenor Gallery, as well as by the enormous and increasing growth of the Westinghouse company in America. Even Mr. Harold P. Brown, we should think, must at heart accept the deductions he would have us draw from his experiments with several reservations, in the face of such a remarkable manifestation of public favor.—*The Electrician* (London).

CONSOLIDATION OF ELECTRIC LIGHT COMPANIES.

The consolidation of the Westinghouse and United States companies, is an event of unusual importance in the electric lighting business. Until within a short time the manufacture of electric lighting apparatus, both arc and incandescent, was practically in the hands of six corporations, viz., the Brush, Edison, Thomson-Houston, Westinghouse, United States and Sawyer-Man companies. The Westinghouse company having leased the Sawyer-Man and assumed the control and management of the United States company, the number is now practically reduced to four. The new combination, however, now greatly exceeds either of the others in extent of manufacturing facilities, volume of business, and number of important patents owned.

The United States is the successor of the Weston Electric Light Co., which was organized July 7, 1877. It owns the inventions of Edward Weston, Moses G. Farmer, and other prominent inventors, which cover many early inventions relating to electric lighting. Some of these are of a fundamental character, especially those relating to dynamo machines, automatic regulation and incandescent lamps, not a few of which antedate even

the work of Mr. Edison in this field. Having been in active and extensive operation for 12 years it has several hundred plants in operation, besides a number of central stations. Its manufacturing business amounts to more than $1,000,000 per year, and includes dynamos, motors, fittings, fixtures, and arc and incandescent lamps. Its Newark factory has a capacity for making 5,000 incandescent lamps per day, and other material in proportion.

The Westinghouse company has, in a little over two years, taken the first rank in the incandescent lighting business, having sold 143 central station plants, having a total capacity of 250,000 16-candle incandescent lights in actual operation. It recently purchased the Waterhouse company, of Hartford, and has commenced the manufacture of arc lighting plants on that system, having now in hand an order for 1,200 arc lamps, and a corresponding outfit of dynamos for lighting the City of Pittsburgh. The combined capacity of the consolidated companies is equivalent to 15,000 incandescent lamps per day, or 4,500,000 lamps per year, and there is every indication that the capacity of the works will soon be fully tested. It is now preparing to manufacture Tesla motors in large quantities for use in connection with alternating stations.

STORAGE BATTERIES.

TEMPORARY INSTALLATIONS.

The storage battery is found to be a most convenient and effective means of providing electric illumination for special occasions—such as balls, dinners, and other large social entertainments—abundant and artistically arranged lights enable the decorator to enhance his effects to a surprising degree.

A particularly successful use of accumulators for this purpose was made on the occasion of the ball at Dr. Webb's city residence, January 11. The outfit was furnished and placed by the Electrical Accumulator Co.

The following is from the report of Mr. Geo. B. Prescott, Jr., electrician of the company.

"* * * The following are the main points in relation to the temporary installation of accumulators at Dr. Webb's ball on last Friday evening:—

"There were two series of 35 cells each of the Electrical Accumulator Co.'s "15 A" cells, which were connected in parallel and supplied current for 90 16 c. p. lamps, from 6 o'clock in the evening until 4 o'clock in the morning. These cells were charged at the company's works at Newark and carted to Dr. Webb's residence on the day of the ball, where they were placed in the basement. The lamps were used for the illumination of the ball-room and the banquet hall. In the former there were 60 lights which were suspended from the cornices and formed a border on four sides of the room. Beneath the lights was stretched a width of very thin transparent pongee silk which agreeably tempered the light and gave it a pink tinge. The ceiling and walls of this room are very handsomely frescoed, and the light illuminated the paintings so effectively that they displayed beauties that had not before been noticed by the family. In the dining hall there were 30 lights distributed in a somewhat similar manner, the lamps being enclosed in decorative globes, some of cut glass and others, opal, arranged uniformly between the carved panels of the wall. The effect in both rooms was magnificent, and no accident or hitch of any kind occurred."

THE TELEPHONE.

ST. LOUIS.—THE NEW TELEPHONE BUILDING.—The Bell Telephone Co. of Missouri will soon be the possessors of an extremely handsome building. Work will be commenced at once on the plans of Messrs. Shepley, Rutan & Coolidge, architects, of Boston, whose design was chosen from several competing plans. The building is to be located on the southeast corner of Tenth and Olive streets. The site is 50 feet on Olive street by 109 feet on Tenth street. The building is to be seven stories high, and fireproof throughout. It will present a very striking and solid appearance. The cost will be about $125,000. The intention is to rent the first five stories and half of the sixth. The executive offices of the telephone company will occupy the west half of the sixth floor, the elevator coming up from the rear on the Tenth street side. The seventh floor will be occupied exclusively by the telephone operating room.

ELECTRIC LIGHT AND POWER.

ST. LOUIS.—The four electric light companies doing business in this city were consolidated to-day. The companies are the Brush, the Thomson-Houston, the Metropolitan Light and the Western Light Association. The stockholders of the Brush association, it is understood, have agreed to accept Thomson-Houston stock of par value, $100 for Brush Electric Association stock, share for share, and turn over the entire stock of their company, which would, of course, carry that company's plant, wires, franchises and business. The Thomson-Houston stock is worth probably $125, and has paid 2½ per cent. per month for some time. The terms of the deal with the Western are not known on the street further than that some stock and some cash will be given for the Western plant, franchises and business, and the Chicago people agree to keep out of St. Louis. The same terms have been accepted by the Metropolitan company. D. R. Powell, president of the Thomson-Houston, says the combination is not a trust, but that his company has purchased the other three.—*Press despatch*, January 7.

MORE ALTERNATING TRANSFORMER SYSTEMS.—It is learned from an authoritative source that the Brush Electric Co. is about to put a new alternating 2,000 volt transformer system on the market. This system is said to resemble very much the alternating system of the Anglo-American Brush corporation of London, brought out last summer by its electrician, Mr. Mordey. The Mordey alternating dynamo belongs to the type which has a stationary armature, with one internal field coil and large iron keepers revolving.

It is also learned that the Zipernowski-Deri system is soon to be introduced in the United States. Ganz & Co., of Budapest, the owners of the system, several years ago made an agreement with a leading American company, which is an advocate of the direct current incandescent system. This company, it is said, has never sold, and in fact, never tried to sell, a Zipernowski-Deri outfit, and thus practically shut the system out of the country, besides breaking the spirit of its agreement. At least Ganz & Co., a firm of enormous capital, whose electrical department represents only a fraction of their business, seem to have come to this conclusion. They are now ready, it is asserted, to negotiate or have already reached an agreement with an American company for the purpose of introducing their system in the United States.—*Western Electrician.*

A COAL cutter is run by an electric motor in the T. C. Heimes colliery near Osceola, Clearfield county, Pa. It is a 10 h. p. Sprague; is mounted on a truck running upon the rail-track of the mine. It is wheeled to any desired point, and connected to the cutter by a tarred hempen rope running over sheaves with V-shaped grooves, at a distance of about 30 feet.

Foreign.

France.—THE PARIS MUNICIPAL ELECTRIC LIGHT STATION.—The commissioners nominated to decide between the tenders for the steam and electric plant required in the central station have published their decision, which is to the following effect: The order for the boilers was given to the Belleville company, whilst that for the engines is divided between two firms—Messrs. Wehyer and Richmond, who supply three triple expansion engines of 140 h. p., and Messrs. Lecouteux & Garnier, who supply three single cylinder engines of 170 h. p. The dynamos are divided between the French Edison company, who supply six machines each, capable of an output of 400 amperes at 110 volts, and the agent of Mr. Ferranti, who supplies three Ferranti dynamos each of 113 kilo-watts capacity.

MANUFACTURING AND TRADE NOTES.

THE HILL CLUTCH WORKS, Eastern office, 18 Cortlandt street. New York, report that they have closed the contract with the Mt. Morris Electric Light Co., of New York, for the complete equipment of their large new station with everything in the line of power transmission machinery, friction clutches, etc. This station when equipped will be one of the finest in the country. At the start it will have a capacity of 2,000 h. p.

The same concern also report that they have just closed a contract with the United Electric Light Co., of Springfield, Mass., for the complete equipment of their station with friction clutches and everthing in the line of power transmission machinery. The Clutch Works designed this station, and they say when it is equipped it will be a fair rival, in point of fine machinery and workmanship, to their large plants in St. Paul and Minneapolis, Minn., which are considered in the west to be among the most complete and economical plants yet installed.

SPRAGUE MOTORS.—Mr. H. O. Woodruff, agent, reports the installation in Des Moines, Iowa, during the year 1888 of 18 Sprague motors, as follows: Iowa Printing Co., 20 h. p.; Leader Printing Co., 15 h. p.; Iowa State Register, 10 h. p.; Homestead Co., 5 h. p.; Western Lithograph Co. 5 h. p.; Cheshire Bros., Printers, 3 h. p.; Plymouth Congregational Church, 1 h. p., and 11 smaller ones for a variety of manufacturing and domestic uses.

THE WRIGHT ELECTRICAL ENGINEERING CO., of Boston, Mass., has been organized as a contracting and construction company. Mr. Alex. P. Wright, well known as superintendent of the Springfield, Mass. central station, and from his still earlier work as an old-time telegrapher is at the head of the enterprise. The company will enter largely in central station and railway work.

MR. W. L. ADAMS, formerly junior partner of Dickerman, Adams & Co., of Boston, agents for the Eddy motor for the New England states, has sold his interest in that firm and will engage in business for himself. Mr. Dickerman continues the firm's business.

MR. F. E. PETTINGELL, of Boston, has now associated with him Mr. Andrews, as junior partner, the firm name standing, Pettingell, Andrews & Co.

THE JOHNSON ELECTRIC CO., 14 Mt. Washington ave., Boston, Mass., has recently been incorporated. The company will manufacture a secondary battery of Mr. Johnson's invention.

THE ADVANCE ELECTRIC CO., 848 Congress street, Boston, have begun the manufacture of the Ward and Sloan battery. This company show the results of tests over the signature of Professor Dolbear, which are surprising for primary batteries.

THE WESTERN ENGINEERING CO.—The following is from the Kearney (Neb.) *Hub*, of January 5. :—"Negotiations have been carried on for some time past, and the contract has been closed, for the Western Engineering Co. of Lincoln, Nebraska, to remove to Kearney. The capital stock of the company has been increased to one hundred thousand dollars and stock all taken. The Western Engineering Co. put the electric plant in this city, and has many contracts throughout our own and adjoining states for other work. It will be a corporation of a high order, employing in its various divisions many hands. The fact is that Kearney is to become the electrical centre of the west."

Messrs. D. C. Jackson and J. G. White, who went west some two years ago from Cornell University, are at the head of this successful company.

THE CALIFORNIA ELECTRICAL WORKS, San Francisco, Cal., we are informed, have recently been appointed agents on the Pacific coast for the "Okonite" wires and cables for aerial, submarine, and underground use, manufactured by the Okonite Company, New York. This company report a large business in these specialties throughout the west.

NEW INCORPORATIONS.

Citizens' Electric Co., of Dudley and Oxford, Mass. Capital, $10,000.

Citizens' Electric Light Co., Webster, Mass., John W. Dobble and others. Capital, $10,000.

Grove Electric Light and Power Co., St. Joseph, Mo. Capital, $1,000,000.

American Electric Railroad Co., Chicago, Ills., H. Henry and others. Capital, $1,000,000.

Calkin Electric Co., St. Johns, N. B., Jeremiah Calkin and others. Capital, $150,000.

Hyde Park District Telegraph and Electric Co., Hyde Park, Ills., James Crape and others. Capital, $10,000.

Perkins Lamp and Electrical Supply Co., Chicago, Ills. Capital, $250,000.

Phœnix Electric Fire Escape Co., Chicago, Ills. William S. Bates and others. Capital, $130,000.

American Heat, Power and Light Co., Chicago, Ills., Jesse Cox and others. Capital, $100,000.

People's Eléctric Light and Power Co., Mount Vernon, N. Y., W. A. Armstrong and others. Capital, $100,000.

Riverton, Palmyra, Mount Holly Electric Light, Power and Heating Co., Mount Holly, New York. Capital, $50,000.

Merchants' Electric Light and Power Co., Birmingham, Ala. Capital, $20,000.

Eighth Street Electric Light Co., Philadelphia, Penn. Capital, $10,000.

Wisconsin Storage Battery Co., Milwaukee, Wis., DeWitt Davis and other. Capital, $10,000.

Continental Dynamo Co., Newark, N. J., Charles Schumacher and others. Capital, $20,000.

West Jersey Electric Light, Power and Heating Co., Camden, N. J., G. Harvey Knight and others. Capital, $25,000.

Joliet Light, Power and Transit Co., Joliet, Ills., Lewis E. Ingalls and others. Capital, $300,000.

National Electric Light and Motor Co., Victoria, B. C. Capital, $100,000.

Rhodes and Kesse Electrical Co., Los Angeles, Cal., S. J. Kesse and others. Capital, $10,000.

Middleborough Electric Light and Power Co., Middleborough, Mass., Wilbur A. Stiles and others. Capital, $25,000.

Savannah Electrical Co., Savannah, Ga., Herman Myers and others. Capital, $50,000.

Edison Light and Power Co., Portsmouth, Va., H. L. Maynard and others. Capital, $25,000.

Fort Collins Electric Co., Denver, Col., William B. Miner and others. Capital, $50,000.

Freeman Dynamo Electric Motor Co., 89 Liberty St., New York, N. Denison Morgan and others. Capital, $250,000.

St. Louis Electric Light and Power Co., S. M. Dodd and others. Capital, $600,000.

Citizens' Electric Co., Worcester, Mass. Capital, $10,000.

New Ulm Electric Lighting Co., New Ulm, Minn., M. Mullen and others. Capital, $25,000.

Monroe Electric Light and Power Co., Monroe, La. Capital, $25,000.

West Duluth Light and Power Co., West Duluth, Minn., W. T. Tanner and others. Capital, $35,000.

Western Electric Light Co., Milwaukee, Wis., Henry C. Payne and others. Capital, $100,000.

Notes.

ATLANTIC CITY, N. J.—The Pennsylvania Railroad Co. have closed a contract with the Sprague company for the electric equipment of their system of street railway at Atlantic City. Before adopting electric traction for their street cars the company caused a careful examination of the subject to be made by their engineer and experts. The managers of the Sprague Electric Motor and Railway Co. may justly congratulate themselves upon securing the contract.

BOSTON, MASS.—The Sprague Electric Railway, at Boston, which extends from the centre of the city at Park square to Brookline, and is a part of the West End Electric Railway, is now in practical operation, and is carrying a large number of passengers. The cars run easily and are under complete and perfect control, and respond readily in changing the speed to the different movements of the electric switch on the front platform moved by the operator. These operators are not skilled electricians, but for the most part street-car drivers, who have learned the method of operating the electric car after a few hours practice, and who express the opinion universally that it is far easier and more pleasant work than driving horses. The road has been already visited by a large number of street railway men from the neighborhood, and who have appeared to be much pleased with the neatness and unobstructiveness of the overhead system, and general look of stability and reliability of the entire road.

THE THOMSON-HOUSTON ELECTRIC CO., on November 29th, started to equip the Cambridge Division of the West End street railway, of Boston, running from Bowdoin square, via Cambridge street, West Boston Bridge, Main street, to Harvard square, Cambridge, three miles, and thence via North avenue to Arlington, four miles. About six miles of this line is double track and paved.

As the season was so far advanced it was first thought advisable to equip the line as far as Harvard square, and accordingly the rail connections were made from Harvard square to Bowdoin square, and back. This work was completed Dec. 3d. In view of the fact that the cars on this division of the West End street railway run on a headway of less than two minutes, it will be seen that remarkably good time was made by the Thomson-Houston company in removing the paving and drilling and connecting the rails without interrupting the traffic. The work of connecting the rails on North avenue is also about done. The poles used in equipping this line are made of lengths of strong iron pipe firmly shrunk together and are very neat and unobtrusive. There are three styles of these poles, it being deemed advisable to use a stronger one on the curves than was used on the straight stretches; 300 have been used from Harvard to Bowdoin square. They are set in crushed rock and cement.

The cross suspension method is to be used the entire length of the line. The cross wires from which the trolley wires hang have been stretched, and are in position from Harvard to Bowdoin squares.

The overhead trolley wires are now being placed in position. In order not to interfere with the operation of the cars during this work, a large platform staging is used, which permits passage of the cars underneath it. In connection with the work of equipping the line it may be said that the Thomson-Houston company has had to cope with several difficulties which would not enter into the construction of other lines in this city, and in the overcoming of which no little engineering skill has been employed. One of these points has been the drawbridge over which the two railway tracks run. Owing to its peculiar construction and situation, it has been found necessary, in order to effectually connect the wires, to design a special switch.

At the grade crossing of the Boston & Albany Railroad, in order to avoid raising the trolley wires above the gate, an automatic device will be employed in connection with the gates to prevent interference with the trolley wires. Twenty cars are to be equipped out of those now running on the road, three being fitted up at a time. The work on these is now in progress.

In regard to the power station, it is proposed at present to utilize the station of the Cambridge Electric Light Co., and place therein five 80 h. p. generators and complete switch-board for operating the same. The steam plant is already being placed in the station, and work of setting up the generators has been begun.

When the Thomson-Houston company completes their present contract with the West End street railway, 20 cars will be running from Bowdoin square to Arlington, each of which cars will have sufficient power to tow an additional car. All cars will be lighted with electric lights and equipped with head lights.

DAVENPORT, IA.—The electric railway installed by the Sprague company, has now been in operation over a month, and the president and directors of the road express themselves well pleased with the service. The officers of the road gave a striking proof of their confidence in their electrical outfit by advertising for sale all the horses owned by the company on the date of opening the road. Through the blizzard of Jan. 9th, which created so much disturbance along the Mississippi valley, and which snowed in a number of towns, stopping travel, delaying freight, and otherwise interrupting business, the Davenport electric railway kept on running without missing a trip, or any delay, although the road has a grade from 7¼ to 8 per cent., 1,600 feet long, upon one portion of its line, and several other grades of 6 per cent. with sharp curves.

HARRISBURG, PA.—The managers of the East Harrisburg Street Passenger Railway, operating the Sprague system, are so well satisfied with the practical and financial success of their electric plant that they have ordered an additional number of motor cars.

WASHINGTON, D. C.—The Thomson-Houston road of the Eckington & Soldiers' Home Railway, has been in operation since the latter part of October, and thus far without a hitch of any kind which can be laid to the electrical apparatus. The patronage of the road has increased to such an extent that it has been necessary to double the car capacity. Each motor car now tows an additional car, both of which are filled to their utmost capacity at every trip. The road is considered one of the finest which has been built in the United States, and reflects the utmost credit upon the Thomson-Houston company.

THE THOMSON-HOUSTON ELECTRIC CO. has recently closed a contract with the McGavock & Mt. Vernon street railway of Nashville, Tenn., for the equipment of a part of its road. The length of the line is 3.07 miles, of which 2.30 is double track, and .77 single, making a total length of single track 5.37 miles. There are seven curves on the line and numerous grades, the maximum being 5¼%. There will be six cars, each 16 feet in length, and capable of carrying 75 passengers, and equipped with two 10 h. p. Thomson-Houston motors. The overhead system will be used. Electricity will not be used on the entire line at present, but only upon a loop from Cherry street around by the Public square, back to the stables. The time now consumed by a car making this trip is 70 minutes. The electric cars will make this trip in 30 minutes. The consideration of saving one-half of the time, is a material one for both the company and the patrons of the road. Eight cars are now used on this division, and as the motor cars will be twice as fast, only four of them would be needed, but inasmuch as the company excepts an increased traffic the six cars will be put on as soon as ready. The city council, some weeks ago, granted a right to exchange animal for electric power to all the street railway companies, and if this road prove as successful as other roads operating this system, the remaining branches of the McGavock & Mt. Vernon road will be equipped, and it will, in all probability, be adopted by the East Nashville and South Nashville companies. The company has also closed a contract for the equipment of two miles of single track at Southington, Conn. The overhead line is all completed except on the curves, which are now being put in. The bracket method of suspension is employed except on the curves, where the cross suspension is used. The cars will be operated, each being equipped with two 10 h. p. Thomson-Houston motors.

LEGAL NOTES.

A DECISION AFFECTING THE RELATIONS OF DOMESTIC TO FOREIGN PATENTS.

SUPREME COURT OF THE UNITED STATES.

THE BATE REFRIGERATING COMPANY APPELLANT, *vs.* GEORGE H. HAMMOND & COMPANY.

Appeal from the Circuit Court of the United States for the District of Massachusetts.

Mr. Justice BLATCHFORD delivered the opinion of the Court, January 21st, as follows :—

This is a suit in equity, brought in the Circuit Court of the United States for the District of Massachusetts, December 16, 1886, by the Bate Refrigerating Company, a New York corpora-

tion, against George H. Hammond & Company, a Michigan corporation, founded on the alleged infringement of Letters Patent No. 197,314, granted to John J. Bate, November 20, 1877, for the term of seventeen years from that day, on an application filed December 1, 1876, for an "improvement in processes for preserving meats during transportation and storage."

The plaintiff is the assignee of the patent. The bill alleges infringement, within the District of Massachusetts and elsewhere in the United States, by the making, using and vending of the patented process, and alleges that the defendant has been engaged in the business of shipping fresh meat from the port of Boston to ports in Great Britain, by means of the process claimed in the patent. The claim is as follows: "The herein described process of preserving meat during transportation and storage, by enveloping the same in a covering of fibrous or woven material, and subjecting it when thus enveloped to the continuous action of a current of air of suitably low and regulated temperature, substantially as and for the purpose set forth."

The defendant filed a plea, setting up, among other things, that, on the 9th of January, 1877, letters patent of the Dominion of Canada, No. 6,938, for the same invention as that described and claimed in No. 197,314, were granted to the same John J. Bate, for the term of five years from the 9th of January, 1877; that after No. 197,314 had expired, at the end of the term of five years for which such Canadian patent was granted, the Circuit Court of the United States for the District of New Jersey, upon being advised of the grant of such Canadian patent, vacated and set aside an injunction which it had theretofore granted, by an interlocutory decree made in a suit in equity founded on No. 197,314, brought by the Bate Refrigerating Company against Benjamin W. Gillett and others; that thereafter Bate and the Bate Refrigerating Company procured the rendition of a judgment by the Superior Court for Lower Canada, declaring the Canadian patent to have been void *ab initio*, and vacating it and setting it aside; that such judgment of the Superior Court for Lower Canada being brought to the attention of the Circuit Court of the United States for the District of New Jersey, that Court reinstated said injunction; and that afterwards the Superior Court for Lower Canada, in a suit brought by Sir Alexander Campbell, Minister of Justice and Attorney-General for the Dominion of Canada, against Bate and the Bate Refrigerating Company and others, adjudged that its said prior judgment had been "arrived at through the fraud to the law and collusion" of Bate, the Bate Refrigerating Company, and another person, "deceiving the Attorney-General, the advocates, and the Court, employing and paying counsel on both sides, as well, seemingly, against themselves as on their apparent behalf," and revoked and annulled its said prior judgment. The plea concluded by averring that No. 197,314 expired on the 9th of January, 1882, and that the Circuit Court, sitting as a Court of Equity, had no jurisdiction to hear and determine an action in equity for the infringement of the patent.

The bill was then amended by averring that the application for the Canadian patent was not made until December 19, 1876, while the application for No. 197,314 was made December 1, 1876, and that the Canadian patent was not actually or legally issued until on or about June 26, 1878, on or about which date a model of the invention, as required by law, was filed in the Canadian Patent Office. The amendment to the bill also set forth the two judgments of the Superior Court for Lower Canada, and averred that by virtue of an act of the parliament of the Dominion of Canada, assented to May 25, 1883 (46 *Victoria, chap.* 19), the original term of the Canadian patent was actually fifteen years, instead of five years, and it would not terminate before the 9th of January, 1892.

Subsequently the defendant filed an answer to the bill, setting up among other defenses, want of novelty in the patented invention, but not denying that it had used the invention subsequently to the granting of the patent, and also setting up the granting of the Canadian patent for five years from January 9, 1877; that No. 197,314 was void, because it was issued for seventeen years, and its term was not limited by the Commissioner of Patents to five years from January 9, 1877; that the Canadian application was not made until after the application for No. 197,-314 was filed; that Bate did not file a model in the Canadian Patent Office until after the grant of the Canadian patent, and that the Canadian patent was actually patented to Bate on the 9th of January, 1877, and took effect on that date, although not actually delivered to the patentee until after the filing of the model. It also sets forth the two Canadian judgments, and avers that, on the 30th of November, 1881, Bate made a petition to the Commissioners of Patents for Canada, for the extension of No. 6,938, in which he averred that on the 9th of January, 1877, he "obtained a patent for the period of five years from the said date, for new and useful improvements on apparatus and process for ventilation, refrigeration, &c," and that he was the holder of that patent in trust for the Bate Refrigerating Company, and prayed that it might be extended "for another period of ten years;" that, on the filing of that petition, an extension of the patent was granted on December 12, 1881, "for a second period of five years" from January 9, 1882; that a further extension of the patent was granted December 13, 1881, "for a third period of five years" from January 9, 1887; that the plaintiff is thereby estopped from denying the fact that No. 6,938 was legally granted January 9, 1877, for a period of five years; that by virtue of the act of 46 *Victoria Chap.* 19, the original term for which No. 6,938 was granted was not 15 years instead of five years; that said act can have no effect on the duration of No. 197,314; that by reason of the prior patenting of the invention by Bate in Canada for five years from January 9, 1877, No. 197,314, if valid at all, expired on January 9, 1882; and that, therefore, this court, sitting in equity, has no jurisdiction to hear and determine an action for its infringement.

Without the filing of any replication to this answer the parties entered into a written stipulation, setting forth as follows: "Whereas, the answer of the defendant corporation in this cause sets up, in addition to other defenses, that the patent on which this suit is brought, being No. 197,314, granted to John J. Bate, complainant's assignor and president, on the twentieth day of November, A. D., 1877, expired on the ninth day of January, A. D. 1882, by reason of the prior grant to said John J. Bate of a patent in the Dominion of Canada for the same invention, and prays the same benefit of said defense as if the same had been pleaded to the bill of complaint; and, whereas, both parties desire to have said matter of defense argued and decided without incurring the great expense of taking testimony necessary to present for final hearing all the defenses raised in said answer: It is, therefore, stipulated and agreed by and between the parties that the defense above named shall be submitted to the court, as on plea set down for argument, upon the following agreed state of facts." The facts so agreed to were substantially as follows:—

1. The patent in suit, No. 197,314, was granted to John J. Bate on November 20, 1877, and the application therefor was filed in the United States Patent Office, December 1, 1876; and said patent was assigned to complainant before this suit was brought, the said Bate being a citizen of the United States at the time of said application, and the said invention having been made and reduced to practice by him therein.

2. On December 19, 1876, said John J. Bate filed in the Patent Office of the Dominion of Canada an application for a patent for improvements in apparatus and processes for ventilation, refrigeration, etc., including therein as one feature, the process described and claimed in said patent No. 197,314.

3. In pursuance of said application the Commissioner of Patents for the Dominion of Canada caused letters patent of the Dominion of Canada, No. 6,938, for the invention set forth in said application, and granted to said John J. Bate, his executors, administrators and assigns, the exclusive right, privilege and liberty of making, constructing, using and vending to others to be used, the said invention, to be signed and sealed with the seal of the Patent Office on January 9, 1877, and to be registered on January 11, 1877, and that the period of said grant expressed in said patent was five years from and after January 9, 1877.

4. On January 12, 1877, said Commissioner of Patents called upon said John J. Bate to furnish to the Patent Office a model of his said invention, and such model was furnished by said Bate on June 26, 1878, on which day said patent No. 6,938 was mailed to said John J. Bate.

5. On December 5, 1881, said John J. Bate filed a petition in the Canada Patent Office, setting forth "that on the 9th day of January, A. D. 1877, your petitioner obtained a patent for the period of five years from the said date for new and useful improvements on apparatus and process for ventilation, refrigeration, etc.; that he is the holder of the said patent in trust for the 'Bate Refrigerating Company,' and therefore prays that it may be extended for another period of ten years."

6. On December 12, 1881, said patent No. 6,938 was extended for five years from January 9, 1882, under renewal No. 13,812, and on December 13, 1881, said patent was further extended for five years from January 9, 1877, under renewal No. 13,818, in pursuance of the above-named petition.

7. On or about July 9, 1883, and June 30, 1886, the Superior Court for Lower Canada rendered two judgments affecting said Canada patent, to the purport set forth in the plea and the answer.

The stipulation further provided, that, if the decision of the Circuit Court should be in favor of the plaintiff, it should have a reasonable time thereafter to file a replication to the answer, and the cause should proceed in the ordinary manner; that, if the Circuit Court should decide the cause in favor of the defendant, a decree should be entered dismissing the bill, so that the plaintiff might take an appeal therefrom to the Supreme Court of the United States; and that, if the Circuit Court should decide the cause in favor of the defendant, and the Supreme Court of the United States should, on appeal reverse that decision, the defendant should have a right to proceed in the Circuit Court, under its answer, as to all defenses set up therein except the one mentioned in the stipulation, as it might have proceeded if the stipulation had not been made.

The cause was heard on the pleadings and stipulation, and the Circuit Court entered a decree dismissing the bill, from which decree the plaintiff has appealed to this Court. The Circuit Court gave no opinion on the merits of the case, but in deciding it followed, as it stated, the decision of the Circuit Court of the

United States for the District of New Jersey, held by Mr. Justice Bradley, in August, 1887, made in the case of *Bate Refrigerating Co. vs. Gillett* (31 *Fed. Rep.*, 809).

The questions discussed at the bar arise under Section 4,887 of the Revised Statutes, which is as follows: "No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force for more than seventeen years."

Two propositions as to the construction of this section are contended for by the appellant: (1) That the words "first patented or caused to be patented in a foreign country" do not mean "first patented or caused to be patented" before the issuing, or granting, or date, of the United States patent, but mean "first patented or caused to be patented" before the date of the application for the United States patent; (2) that the declaration of the section, that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one at the same time with the one having the shortest term," does not mean that the patent so granted shall expire at the same time with the term to which the foreign patent was in fact limited at the time the United States patent was granted; but that it means that it shall expire when the foreign patent expires, without reference to the limitation of the term of such foreign patent in actual force at the time the United States patent was granted.

We do not find it necessary to consider the first of these questions, because we are of opinion that the proper construction of Section 4887, upon the second question is, that the patent in the present case does not expire before January 9, 1892, the time when the Canadian patent, No. 6938, will expire.

The Canadian patent was extended for the two periods of five years each, under the provisions of Section 17 of the Canadian Act assented to June 14th, 1872 (35 *Victoria, Chap.* 26), which was in force when the United States patent, No. 197,314 was applied for and granted, and which read as follows: "17. Patents of invention issued by the Patent Office shall be valid for a period of five, ten, or fifteen years, at the option of the applicant, but at or before the expiration of the said five or ten years the holder thereof may obtain an extension of the patent for another period of five years, and after those second five years may obtain a further extension for another period of five years, not in any case to exceed a total period of fifteen years in all; and the instrument delivered by the Patent Office for such extension of time shall be in the form which may be from time to time adopted, to be attached, with reference to the patent, and under the signature of the Commissioner or of any other member of the Privy Council in the case of the absence of the Commissioner."

This statute appears to have been strictly complied with in the present case. The Canadian patent, No. 6938, ran, on its face, for five years from January 9, 1877, and, prior to the expiration of that time, and on the 5th of December, 1881, Bate applied for its extension for ten years; and it was, before the five years expired, and on the 12th of December, 1881, extended for five years from January 9, 1882, and on December 13th, 1881, for five years from January 9, 1887. The Canadian patent, therefore, has never ceased to exist, but has been in force continuously from January 9, 1877. It was in force when No. 197,314 was issued; and it has, by virtue of a Canadian statute, in force when the application for No. 197,314 was filed, continued to be in force at all times since the latter patent was granted. This is true, although the Canadian patent, No. 6938, as originally granted, stated on its face that it was granted "for the period of five years" from January 9, 1877; and although the instrument granting the first extension of five years states that it is granted "for another period of five years, to commence and be computed on and from the ninth day of January, which will be in the year one thousand eight hundred and eighty-two;" and although the instrument granting the second extension of five years states that it is granted "for another period of five years, to commence and be computed on and from the ninth day of January, which will be in the year one thousand eight hundred and eighty-seven." By the language of Section 17 of the Canadian Act of 1872, what was granted under it was "an extension of the patent"—of the same patent—for a further term. Therefore, the Canadian patent does not expire, and it never could have been properly said that it would expire, before January 9, 1892; and hence No. 197,314, if so limited as to expire at the same time with the Canadian patent, cannot expire before January 9, 1892.

Section 6 of the Act of March 3, 1839 (5 Stat. 354), provided that a United States patent for an invention patented in a foreign country more than six months prior to the application of the inventor for the United States patent, should be limited to the term of fourteen years from the date or publication of the foreign patent. Section 25 of the Act of July 8, 1870 (16 Stat. 201), provided that the United States patent for an invention "first patented or caused to be patented in a foreign country," should "expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term; but in no case shall it be in force more than seventeen years." Section 4887 of the Revised Statutes provides, that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than seventeen years."

These provisions of the Act of 1870, and of the Revised Statutes, mean that *the United States patent shall not expire so long as the foreign patent continues to exist, not extending beyond seventeen years from the date of the United States patent, but shall continue in force, though not longer than seventeen years from its date, so long as the foreign patent continues to exist.* Under Section 4887, although, in the case provided for by it, the United States patent may on its face run for seventeen years from its date, it is to be so limited by the courts, as a matter to be adjudicated on evidence *in pais, as to expire at the same time with the foreign patent,* not running in any case more than the seventeen years; but, *subject to the latter limitation, it is to be in force as long as the foreign patent is in force.*

A contrary view to this has been expressed by several Circuit Courts of the United States.

In October, 1878, in the Circuit Court for the District of Rhode Island, in *Henry* vs. *Providence Tool Co.* (3 *Ban. & Ard.*, 501), it was held that the 25th Section of the Act of July 8, 1870, meant that the United States patent should expire at the same time with the original term of a foreign patent for the same invention, without regard to any prolongation of the foreign patent which the patentee might procure from the foreign government. In that case the United States patent was granted October 10, 1871. A British patent for the same invention had been granted to the patentee on the 15th of November, 1860, for fourteen years, and expired November 15, 1874. Thirteen days after the latter date an order was made for the extension of the British patent for four years, the extension bearing date as of the day after the expiration of the original term; but the Court held that the United States patent expired on the 15th of November, 1874.

That decision was followed by the Circuit Court for the Southern District of New York, in *Reissner* vs. *Sharp* (16 *Blatchford*, 383), in June, 1879, which case arose under Section 4887 of the Revised Statutes. In that case the United States patent, granted October 20, 1874, for seventeen years, was held to have expired on the 15th of May, 1878, because a patent was granted in Canada, under the authority of the patentee, for the same invention on the 15th of May, 1873, for five years from that day, although in March, 1878, the Canada patent was extended for five years from the 15th of May, 1878, and also for five years from the 15th of May, 1883.

In *Bate Refrigerating Co.* vs. *Gillett* (13 *Fed. Rep.*, 553), in the Circuit Court for the District of New Jersey, in August, 1882, and in the same suit, in the same Court, in August 1887 (31 *Fed Rep.*, 809), in regard to the patent in question in the present suit, and on the same facts here presented, it was held, on the strength of the two Circuit Court cases above referred to, that the United States patent expired when the original term of the Canadian patent expired.

But we are of opinion that, in the present case, where the Canadian statute under which the extensions of the Canadian patent were granted was in force when the United States patent was issued, and also when that patent was applied for, and where, by the Canadian statute, the extension of the patent for Canada was a matter entirely of right, at the option of the patentee, on his payment of a required fee, and *where the fifteen years' term of the Canadian patent has been continuous and without interruption,* the United States patent does not expire before the end of the fifteen years' duration of the Canadian patent. This is true, although the United States patent runs, on its face, for seventeen years from its date, and *is not, on its face, so limited as to expire at the same time with the foreign patent; it not being necessary that the United States patent should, on its face, be limited in duration to the duration of the foreign patent.*

In *O'Reilly* vs. *Morse* (15 *How.*, 62), the patent to Morse was issued June 20, 1840, for fourteen years from that day, while § 6 of the act of March 3, 1839 (5 *Stat.*, 354), was in force, which required that every United States patent for an invention patented in a foreign country should be "limited to the term of fourteen years from the date or publication of such foreign 'letters patent.'" Morse applied for his United States patent April 7, 1838. He obtained a patent in France for his invention October 30, 1838. The objection was taken in the answer that the United States patent was void on its face because not limited to the term of the French patent. The Circuit Court held that the patent was not void, but that the exclusive right granted by it must be limited to fourteen years from October 30, 1838. The same objection was

urged in this Court, and the same ruling was made. In *Smith* vs. *Ely* (15 *How.*, 187), which was a suit on the same patent, under the same facts, the same question arose and was decided in the same way. A full and interesting discussion of the question is to be found in *Canan* vs. *The Pound Mfg. Co.* (23 Blatchford, 178), in regard to § 4,887, which contains the same word "limited" found in § 6 of the Act of 1839, which word is not found in § 25 of the Act of July 8, 1870, from which § 4887 was taken.

Under this view the time of the expiration of the foreign patent may be shown by evidence *in pais*, whether the record of the foreign patent itself, showing its duration, or other proper evidence; and it is no more objectionable to show the time of the expiration of the foreign patent by giving evidence of extensions such as those in the present case, and thus to show the time when, by virtue of such extensions, the United States patent will expire.

We find in the record in this case, among the papers which it states were submitted to the Court under the stipulation above referred to, a certificate of the Commissioner of Patents, dated July 8, 1883, appended to a certified copy of the United States patent, stating that the term thereof is limited so that it shall expire with the patent obtained by the patentee in Canada, No. 6938, dated January 9, 1877, for the same invention; that the proper entries and corrections have been made in the files and records of the Patent Office; that it had been shown that the original patent had been lost, and that the certificate is made because that patent was issued without limitation, as required by Section 4887 of the Revised Statutes. While it may be proper, in a case where the date of a foreign patent, issued prior to the granting of a United States patent to the same patentee for the same invention is made known to the Patent Office prior to the granting of the United States patent, to insert in that patent a statement of the limitation of its duration, in accordance with the duration of the foreign patent, *it does not affect the validity of the United States patent if such limitation is not contained on its face.*

It results from these views, that the decree of the Circuit Court must be reversed, and the case be remanded to that Court with a direction to take such further proceedings as shall be in accordance with law and with the stipulation between the parties above referred to, and not inconsistent with this opinion.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From December 25, 1888 to January 15, 1889 (inclusive).

Alarms and Signals:—*Automatic Fire-Alarm*, A. Watson, 395,096. *Signal-Transmitter*, J. C. Wilson, 395,101 and 395,102. *Fire Alarm Annunciator*, W. A. Barnes, 395,111. *Electric Alarm*, same, 395,112, December 25. *Electric Signaling Apparatus*, J. P. Coleman, 395,315, January 1; M. W. Dewey, 395,-958 and 395,959, January 8; W. Henion, 396,207, January 15.

Clocks:—*Controlling Device for the Regulating Members of Clocks*, W. S. Scales, 395,357, January 1.

Conductors, Insulators, Supports and Systems:—*Process of Manufacturing Insulated Conductors*, W. Siemens, 395,083. *Electric Cable Support*, C. H. Bowen, 395,207, December 25. *Electric Cable*, W. A. Conner, 395,546. *Conduit for Electric Wires or Cables*, E. H. Phipps, 395,584, January 1. *Support for Aerial Electric Conductors*, H. H. Cutler, 395,814, January 8. *Insulator Support for Electric Conductors*, L. Daft, 396,196. *Overhead Insulator*, S. H. Gilson, 396,334, January 15.

Dynamos and Motors:—*Dynamo-Electric Machinery*, F. Von Hefner-Alteneck and C. Hoffmann, 395,019. *Core for the Armatures of Dynamos*, D. J. Hauss, 394,978. *Brush for Dynamos*, E. W. Rice, Jr., 394,999. *Circuit-Controller for Dynamo-Electric Machines*, T. A. Edison, 395,123. *Dynamo-Electric Machine*, F. F. Loomis, 395,157. *Armature for Dynamo-Electric Machinery*, W. S. Belding, 395,260. *Electric Motor*, D. F. Sweet, 395,299, December 25. *Dynamo-Electric Machine*, J. F. Kelly, 395,622, January 1. *Synchronizing Device for Dynamo-Electric Machines*, C. Hoffmann, 396,086. *Thermo-Magnetic Motor*, N. Tesla, 396,121. *Unipolar Dynamo Electric Machinery*, R. Eickemeyer, 396,149. *Armature for Dynamo-Electric Machines*, L. Daft, 396,195. *Electro-Dynamic Machine*, C. Coerper, 396,269. *Commutator-Brush Carrier for Electric Motors*, C. J. Van Depoele, 396,314. *Dynamo-Electric Machinery*, I. T. Dyer, 396,355, January 15.

Galvanic Batteries:—*Battery-Cell for Electric Belts*, S. Colling, 394,958, December 25. *Dry Voltaic Battery*, I. Kitsee, 395,706. *Voltaic Battery*, T. Coad, 395,769. *Mode of Preparing Solution Compounds for Galvanic Batteries*, W. P. Kookogey, 395,835. *Method of Preparing Solution Compounds for Galvanic Batteries*, same, 395,837, January 8. *Galvanic Battery*, P. R. De F. D'Humy, 396,329; B. Scheithauer, 396,342, January 15.

Ignition:—*Electric Appliance for Discharging Guns*, B. A. Fiske, 396,199, January 15.

Lamps and Appurtenances:—*Sign for Electric Lights*, E. A. Dubey, 395,317, January 1. *Holder for Electric Arc Lamps*, J. Pawlowski, 395,755. *Regulator for Incandescent Electric Lighting Systems*, M. J. Wightman, 395,936. *Method of Manufacturing Electric Lamps*, T. A. Edison, 395,962. *Incandescent Lamp Filament*, same, 395,963. *Coupling for Gas and Electric Light Fixtures*, R. Herman, 396,039, January 8. *Head-Light*, J. F. Shawhan, 396,241, January 15.

Measurement:—*Electric Meter*, E. Thomson, 395,018, December 25. *Electrical Measuring Apparatus*, H. V. Hayes and A. C. White, 395,974, January 8.

Medical and Surgical:—*Medical Battery*, H. E. Waite, 395,932, January 8. *Electrical Body-Wear*, J. V. Long, 396,212, January 15.

Metal Working:—*Mode of Covering Surfaces of Metal with Lead*, O. Elberling, 395,269, December 25. *Manufacture of Electrotype of Stereotype Plates*, J. Dale, 395,488, January 1. *Cathode for an Electro-Depositing Apparatus*, E. Emerson, 395,773. *Process of Electric Welding*, C. L. Coffin, 395,878. *Forming, Brazing and Welding of Metals by Electricity*, E. Thomson, 396,009. *Method of Electric Forging*, same, 396,010. *Method of Electric Welding*, same, 396,011. *Apparatus for Electric Welding and Working Metals*, same, 396,012. *Electric Pipe-Joining and Pipe-Work*, same, 396,013. *Electric Metal Working*, same, 396,014. *Method of Electric Riveting*, same, 396,015, January 8. *Process of Electric Welding*, C. L. Coffin, 396,270. *Magnetic Separator*, T. A. Edison, 396,356, January 15.

Miscellaneous:—*Overloading and Slack Cable-Stop for Electrical Hoisting-Machines*, W. Baxter, Jr., 394,952. *Rheostat*, S. Bergmann, 395,116. *Toll Apparatus for Producing Electric Light*, D. H. Davies and J. M. Tourtel, 395,215, December 25. *Lightning-Rod*, L. L. Mast, 395,399. *Safety-Device for Use in Electric Circuits*, A. C. Cockburn, 395,421. *Regulator*, A. Gartner, 395,492. *Electrically-Operated Cutting Device*, R. Thayer, 395,524. *Automatic Safety Cut-Out for Electric Circuits*, G. T. Woods, 395,533. *Electro-Magnetic Rock-Drill*, H. N. Marvin, 395,575. *Electrical Switch*, P. H. Brangs, 395,609. *Wire Splicer and Cutter*, H. V. Wulbecke, 395,642, January 1. *Art of Compiling Statistics*, H. Hollerith, 395,781. *Apparatus for Compiling Statistics*, same, 395,783. *Apparatus for Indicating and Recording Changes at a Distant Point*, G. E. Winslow, 395,862. *Electrical Heating*, J. V. Capek, 395,950. *Electrical Store-Service Apparatus*, R. N. Dyer, 395,961, January 8. *Attachment for Pianos*, F. W. Hale, 396,156. *Electric Coupling for Hose-Pipes*, D. J. Simpson, 396,176, January 15.

Railways and Appliances:—*Device for Automatically Stopping Trains*, I. L. Meloon and P. S. Whiting, 395,163, December 25. *Conduit Electric Railway*, B. Jennings, 395,442. *Electric Railway Signal*, D. G. Smith, 395,667, January 1. *Electric Train-Brake Apparatus*, A. I. Ambler, 395,682. *Trolley for Electric Railways*, W. F. Jenkins, 395,703. *Conduit for Electric Railways*, S. Trott, 395,761, January 8. *Suspended Switch for Electric Railways*, C. H. Wells, 396,124. *Traveler for Electric Railways*, C. J. Van Depoele, 396,310. *Hooked Suspender for Electric Railway Conductors*, same, 396,311. *Suspension Device for Electric Railway Conductors*, same, 396,312. *Adjustable Crossing and Switch for Overhead Conductors*, same, 396,313. *Railway Signal*, W. C. Paul and O. D. Kleinsteuber, 396,365, January 15.

Storage Batteries:—*Flexible Sealed Cell for Secondary Batteries*, M. Baily and J. Warner, 395,028, December 25. *Insulating Support for Secondary Battery Electrodes*, H. F. De B. Cameron, 395,311. *Secondary Battery Charging*, C. F. Brush, 395,377, 395,378 and 395,379, January 1. *Apparatus for Charging and Discharging Secondary Batteries*, W. P. Kookogey, 395,836, January 8. *Secondary Battery*, O. Lugo, 396,213 and 396,214; I. L. Roberts, 396,367, 396,368 and 396,369, January 15.

Telegraphs:—*Electric Telegraphy*, M. W. Dewey, 394,960. *Telegraphic Printing Code*, same, 394,961, December 25. *Automatic Telegraphy*, P. B. Delany, 395,427. *Multiplex Telegraphy*, F. J. Patten, 395,508, 395,509 and 395,510. *Vibratory Multiplex Telegraphy*, S. D. Field, 395,556. *Electro-Harmonic Telegraphy*, M. W Dewey, 395,613. *Printing Telegraph*, same, 395,614, January 1.

Telephones, Systems and Apparatus:—*Telephone Apparatus*, U. H. Balsley, 394,951. *Electric Switch-Board*, I. H. Farnham, 394,964. *Hotel Telephone System*, 395,187, December 25. *Speaking Telephone*, F. Blake, 395,476, January 1.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in February 1889.

Reported for the ELECTRICAL ENGINEER, *by* F. B. Brock, *Patent Attorney*, 639 *F street, Washington, D. C.*

Fire Telegraph, W. H. Mumler, 123,355; *Magneto-Electric Machine*, A. N. Allen, 123,438; *Gas-Lighting, Electric*, A. N. Allen, 123,439; *Telegraphs*, W. C. Barney, 123,441; *Electric Railway Signal*, H. S. L. Bryan, 123,449; *Relays and Sounders*, G. Little, 123,490; *Automatic Telegraph*, G. Little, 123,491; *Railway Signal*, Verny & Veillet, 123,527, February 6, 1872. *Lightning Rod*, Wells & House, 123,600; *Automatic Telegraph*, G. Little, 123,711, February 13, 1872. *Annunciator*, C. E. Churnock, 123,808; *Insulator*, D. R. P. Emminger, 123,878; *Arc-Light*, A. A. Meynial, 123,923; *Electrolysis*, J. H. Rae, 123,932; *Lightning Rods*, D. F. Welsh, 123,958; *Fire Telegraphs*, Wright, Holley & Miles, 123,970, February 20, 1872. *Automatic Fire Telegraph*, T. A. Edison, 123,984; *Electric Clock*, E. Wilson, 124,104; *Gas Lighting*, S. Gardiner, Jr., 124,126, February 27, 1872.

[Drawings and specifications of any patent will be furnished by Mr. Brock at cost, 15 cents each.]

THE

ELECTRICAL ENGINEER.

Conducted by F. L. POPE AND G. M. PHELPS.

PUBLISHED MONTHLY AT

11 Wall Street, New York City.

TERMS OF SUBSCRIPTION.

United States and Canada, - - - - - - per annum,	$3.00
Four or more Copies, in Clubs (each) - - - - - "	2.50
Great Britain and other Foreign Countries within the Postal Union "	4.00
Single Copies, -	.30

[*Entered as second class matter at the New York, N. Y., Post Office, April 9, 1888.*]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VIII. NEW YORK, MARCH, 1889. No. 87.

THE DECISION OF THE COMMISSIONER OF PATENTS IN THE TELEPHONE INTERFERENCES.

WE have delayed this issue of the ELECTRICAL ENGINEER to print in full the decision of the Commissioner of Patents in the long pending interferences between Bell, Gray, McDonough and others, because of its scope, significance and general interest.

The decision derives much of its interest and significance from the fact that it covers substantially all the charges of fraud made in the pending Government suit to annul the Bell patents. This puts the Government suit in a rather curious position. The United States, through its Attorney-General—who does not know anything about such matters—alleges by a bill, which nobody swears to, that there ought to be inquiry as to whether there was any malpractice or fraud in the Patent Office. Now the United States, by the officer who does particularly know of such matters, in the exercise of its undoubted jurisdiction, summoned Mr. Bell into the Patent Office before that bill was filed, and heard argument after it was filed, and made the very inquiry which the Attorney-General says ought to be made, and decides that all those charges are groundless. This case before the Commissioner of Patents, which consists of a motion of Gray for leave to amend, and a motion of Gray and a motion of McDonough to reopen, has been argued at very great length in the Office. In March, 1887, the McDonough motion was heard before Commissioner Montgomery, General Duncan and Mr. Jefferson Chandler—the latter being one of the Government counsel in the suit against Bell,—appearing for McDonough. In May, 1887, Gray's motion to amend was argued before the Primary Examiner, who decided against him, and was again argued before the Commissioner in person the first week in December, 1887, by Mr. Phillipp and Mr. Casey Young, for Gray; Mr. Conkling and Mr. Storrow against him. The motion of Gray and the motion of McDonough to reopen were argued for eight days before the Commissioner, beginning February 1, 1888, by Col. Ingersoll, Mr. Frank Hurd and Mr. Humphreys, counsel for the Meucci Co., as counsel for McDonough. It was also argued by Mr. Casey Young orally, and by Mr. Phillipp subsequently in a long printed brief, for Gray. By consent of Mr. Bell's counsel they pitchforked in everything they could find in any of the other cases, including the evidence at the hearing before the Secretary of the Interior in the fall of 1885, and all this was argued on the first occasion by one of the Government counsel, though on a rather limited part of the case, and later by the Pan-Electric counsel and by Gray's and McDonough's special counsel. The case might well have been dismissed on the ground of laches, but at the hearing the Bell counsel as well as the Commissioner expressed their disinclination to that course. In the present decision the Commissioner has gone at great length into the whole intrinsic merits of the controversy, and has declared that he reaffirms the earlier decisions because they were right.

It is interesting to refer to the decision of Secretary Lamar, in which he said that he neither formed nor expressed any opinion as to the merits, but merely that there ought to have been an inquiry. There has now been an inquiry of the most elaborate nature, and here is the result.

The present position of the Commissioner is worth noticing also. He was one of the Democratic majority of the Pan-Electric investigating committee; the result of which may fairly be regarded as more political than judicial; he was personally selected by Mr. Secretary Lamar to be Commissioner of Patents, because Mr. Lamar knew him personally and thought very highly of him; and he was appointed by President Cleveland. He has come to this conclusion because no other is possible, and the perusal of the very full statement which he makes of the case will, we believe, convince all candid readers of the justice of the decision.

THE ELECTRIC LIGHT CONVENTION AT CHICAGO.

WE are sorry to have to say it, but the discussions of the February Convention of the National Electric Light Association appear to have been unusually windy, dreary, inconclusive and unprofitable.

The opening address of President Duncan, however, presented a striking array of figures showing the growth of business in electric lighting and railway service during the past year, arranged in a clear and effective manner.

The Association did well, we think, in committing itself to the further continuance of a headquarters in New York under the charge of the Secretary and Treasurer appointed October 1st, Mr. Allan V. Garratt. The permanency of the office as now established depends chiefly upon the pecuniary resources of the Association. With an adequate representation of the thousand or more central station operating companies of the country in the membership, that question would settle itself promptly. While we can-

not regard the proceedings of the recent convention as likely to prove attractive to electrical companies or firms eligible to membership, we believe that the experiences at Chicago, of all who took interest enough in what was said and done on the floor of the convention and elsewhere, point out unmistakably not only the existence of breakers ahead but how to steer away from them. It is a gratifying circumstance that there was substantial unanimity in all action taken by the convention as to the administration of the affairs of the Association for the coming year, including the appointment of a committee to revise the constitution, which proves imperfect in several respects notwithstanding its revision six months ago.

The unanimous election of Mr. Edwin R. Weeks to the presidency ensures a wise oversight of the Association's interests and a judicious consideration of its future policy.

The Association owes its inception, we believe, to the initiative of Mr. Geo. S. Bowen, of Elgin, Ill., who saw clearly the possible usefulness of an organization of practical men, operating electric plants for the purpose of making money for their owners, with meetings for the interchange and comparison of experiences and the suggestion or adoption of improved methods of practice and administration. During its five years existence much has been done to justify Mr. Bowen's endeavors. The relative sterility of the recent convention was unquestionably due to the absorption of general attention in matters quite foreign to the true purposes of the Association, matters necessarily dealt with in committees, conferences and caucuses outside the convention, but bringing every member on the ground under their influence. We do not believe that the conditions which produced such a state of affairs will be permitted to arise again.

The Convention warily declined to commit itself to any deliverance on such questions as Underground Conductors, Petroleum Fuel, Municipal Lighting, etc., but it is a pleasure to record that it braced up to positive action on one subject. Though hungry and anxiously awaiting recess for luncheon, the Association acted promptly and decisively on the preamble and resolution offered by our genial friend, Dr. Moses, touching the pernicious activity of "a certain individual" in "exaggerating the dangers of electric currents" and striving "to influence legislation" to secure "the introduction of electricity" for the infliction of capital punishment. A handsome majority resolutely and manfully voted that the "National Electric Light Association earnestly protests against those efforts and unanimously resolves that the members of this body decline to allow any electric current under their control to be used for ignoble purposes." We may now expect, of course, that the ill-starred agitator will promptly withdraw his objectionable pamphlet from circulation. Even the anonymous notoriety conferred upon him by the Association must prove a fatal blow to his nefarious purposes. It is perhaps regrettable that out of well meant kindness Dr. Moses carefully concealed the identity of the obnoxious person under his designation as "a certain individual."

Can "the individual who happens to be meant" be the eminent electrical engineer whose plan of shutting off a circuit automatically by any accidental grounding, and thus leaving hundreds of people in darkness and danger, was so felicitously characterized by Mr. T. Carpenter Smith on the floor of the convention?

The Electrical Exhibition in connection with the convention was an undeniable success, not only in its extent and variety, but notably in its attractiveness to the people of Chicago. The vast number of visitors was truly surprising.

The new Mayor of New York, Hon. Hugh Grant, takes decided ground in electrical subway affairs. He evidently means to do what he can to get the wires underground, on all routes provided with conduits. Apparently he has no doubt of the entire feasibility of the present subway plans; at all events, he wants to have them faithfully tried, and seems disposed to push forward the construction of conduits on cross-town routes. It would seem wiser to await the result of a thorough trial of existing conduits before laying more. The amusing Mr. Gibbens, always against the Mayor, now takes up the cudgels for the electrical companies, but has already had a knock down or two from Mr. Grant. The new Mayor takes subways too seriously for joking, and we regret the prospect of missing the fun with which Mr. Hewitt and Mr. Gibbens enlivened the tiresome proceedings of the Board of Electrical Control during the former's term of office.

The Metropolitan Electric Supply Company of London, has in our opinion, shown, a wise discretion in awarding the contract for its second central station plant to a home firm of good standing and reputation. With an English and an American concern working at a similar undertaking, under like conditions, and almost side by side, each will be stimulated to show its best work. The contest between these two plants and the great installation at Deptford, will certainly become interesting, and is not unlikely to be very instructive.

Our esteemed transatlantic contemporary, the London *Electrical Review*, is respectfully informed that the only theory, which seems to account for the origin of the mysterious despatch sent out from Buffalo, once upon a time, announcing the total failure of the Westinghouse plant in that city, is based upon the Wellerian hypothesis of coincidences. President Johnson of the Edison Company, is said to have stayed in Buffalo "that wery" same night. But it may be remarked, in passing, that the statement was not true.

In a pamphlet distributed at the Chicago convention, the assertion is made that Walter K. Freeman, now of Eau Claire, Wis., "made and sent to Thomas A. Edison, the first incandescent lamp made with a hight resistance carbon, that he, Edison, had ever seen," and it is therein further stated, that Edison repeatedly admitted to Freeman, in the presence of witnesses, that he received from Freeman an incandescent lamp, upon which he, Edison, based his subsequent experiments. Whether, if true, this is important, would seem to depend largely upon the precise construction of the said lamp, respecting which the author, perhaps wisely, preserves a discreet silence.

AMONG the number of special assemblages to be got together during the French Exhibition, a Congress of Commercial Travelers is announced to be held at Paris, July 9th to 12th. Here is an excellent opportunity for the American drummer. In an "experience" meeting we have little doubt he would be able to hold his own with The Illustrious Gaudissart himself. Although the Congress will be held at a rather warm season, we take the liberty of suggesting to the American delegation some modification of the costume in which the deputation of commercial travelers paid their respects to General Harrison last summer. We fear that the apparition of a considerable body of men arrayed in "long linen dusters, shiny black hats and a new style of umbrella" would prove too much for French gravity.

ONE consequence of the decision of the Supreme Court, in the Bate case we do not remember to have seen touched upon in the numerous discussions which have taken place in relation to the subject. It was held by Judge Wallace in the Circuit Court of New York, in 1886, reaffirming three or four prior Circuit Court decisions in cases in which the facts were similar, that the domestic patent for an invention previously patented abroad for a term of 14 years, does not expire until 14 years from the date of the foreign patent, notwithstanding the grant might have terminated by the failure of the patentee to pay the taxes due at the expiration of three years. This decision would apply to a patent in Great Britain, France, Belgium, and many other countries, but the Supreme Court now holds, apparently, that the domestic patent can only remain in force so long as the foreign patent remains in force. The consequence will be, that many patentees, who under the Circuit Court decisions have always regarded their patents as valid, will find that they have expired by reason of the failure of the owners of the foreign patents to pay the periodical taxes; a discovery, which will no doubt constitute an unpleasant surprise to more than one owner of electrical patents. The doctrine upon which the decisions of the lower courts have uniformly been based, is that the term of the American patent was determined by the condition of the foreign patent at the date of the domestic grant, and that nothing thereafter done to the foreign patent, either by way of extension or curtailment, could in anywise affect the rights of the inventor in this country. The Supreme Court now rejects this doctrine with emphasis, and it appears to us that the consequences in some directions are likely to be serious.

THE decision rendered by the Commissioner of Patents of the Dominion of Canada, revoking Edison's patent of November 17, 1879, for incandescent electric lamps as noted in our news columns, is one of great importance to electric lighting interests in the United States. Under the decision of the United States Supreme Court recently given in the Bate Refrigerator case, Edison's fundamental lamp patent in the United States, No. 223,898, would seem to be dead beyond hope of resurrection. The Canadian decision is final in respect to that jurisdiction, while our Supreme Court, as we have elsewhere pointed out, in commenting upon the Bate case distinctly announces the doctrine that the domestic patent can remain in force only so long as the prior foreign patent remains in force, which is apparently conclusive.

OBSERVATIONS.

ONE of the signs of the times is the facility which the general public, and especially the rising generation exhibits, in adopting and using electrical phrases.

When a person is much astonished or overwhelmed he is *electrified*; we talk of *lightning speed*, or of the *lightning* express. A young teamster who lives in our town, has such a mania for anything electrical, that he not only attends all the lectures and reads with avidity all the books relating to electricity to which he can obtain access, but he also experiments during his spare time, and in his working hours actually speaks of harnessing his horses in *series*, or *multiple arc* as the case may be; and is never at the close of the day tired; he is only *polarized*.

. . .

WAS there ever a more overworked word than this same "polarized;" or a more overworked idea than "polarization?"

An electro-magnet is so mounted upon a permanent magnet that the two poles become of like magnetism, while its armature mounted so as to vibrate between them acquires a magnetic polarity of opposite character: and lo! we have a polarized relay."

A voltaic battery placed on short circuit acquires a deposit of hydrogen over the surface of its negative plate, so that its internal resistance is raised, and so that the ratio between the positive and negative plates in the electro-chemical series is changed; and our battery is "polarized." So again we speak of a beam of "polarized light," etc.

No wonder that the brain of the student often becomes polarized in finding out *all* about electricity.

. . .

THE Boston *Advertiser*, in common with many other daily papers, and doubtless stimulated by the glittering success of the New York *Sun* in its scenes from the real life of celebrated inventors, has established an electrical column. The following head-line recently adorned that column:—

"Electrical Treatment of Alcohol in Beets."—A first glance indicated that a really philanthropic use had at last been found for the invisible force which is always in its infancy; but a calmer and more protracted examination revealed that *Beets* was after all, the proper spelling, and that the item above, referred to a method employed in France for purifying the products of the distillation of beets by means of electricity.

. . .

INCIDENTS in electrical experience repeat themselves as certainly as history does—or as the many coincidences or double occurrences, with which every observer is familiar, in the every-day life of all of us.

Looking over some old files of the *Telegrapher*, a few days ago, the observer came across the interesting account of a Western Union superintendent, who wasn't much on electricity, but take him on authority, and he was there. It stated that this worthy gentleman happened into one of the offices in his district once upon a time, when it chanced that there was but one wire working to Kiachta, a place to which he wished to send a message; "Can't you raise Kiachta" said he? "No," said the operator, "this is the only wire we've got, and I can't raise him on here;" "Switch it round on some of the other instruments," was the reply, "you'll raise him somewhere."

Within an hour after reading of this incident, the observer's attention was called to a similar instances of recent occurrence, in which a telephone official figured as principal. Mr. John Smith (let us say) who is popularly supposed to be perfectly at home with his art, sends a call to Central, and wishes to talk to a storekeeper up-town; in three minutes the operator reports "No. 293 don't answer"; "Don't answer" vociferates J. S., "Tell him he must!"

ARTICLES.

ON THE PLACE OF ACCUMULATORS IN ELECTRIC LIGHTING.

BY GEORGE B. PRESCOTT, JR.

It has been remarked that the electric light will not fulfill all the requirements of an universal illuminant until some method of accumulating and storing electricity for future consumption, similar in effect to that by which illuminating gas is now reservoired in gasometers, has been discovered. Those who are familiar with the subject are aware, however, that the only known method of accumulating electricity *per se*, is through the medium of thoroughly insulated surfaces, as exemplified by the Leyden jar and other forms of condensers; and they know, moreover, that electricity so stored is not available for use in any of the commercial industries in which continuous currents of controllable magnitude and duration are required. The dynamic electricity of batteries and dynamos—if the distinction may be allowed—cannot, therefore, be directly stored for subsequent use in commercial lighting, but it is possible to transform currents so produced into other available forms of potential energy. When so transformed this energy may be controlled at will, and reconverted into electricity at such times and for use in such quantities as may be required.

The storage battery, or modern accumulator, is an instrument capable of effecting this kind of transformation and of bottling up energy so to speak, although, like the primary battery and the dynamo machine, it in no sense stores electricity. In short, the current with which it is charged merely causes certain chemical changes to take place in the constituent elements of the accumulator, and when the charging is discontinued, if the elements are placed in electrical contact, they tend to resume their previous condition, restoring, in the process of reuniting, the electricity which effected the separation.

Whenever one kind of energy is transformed into another kind, more or less loss can be shown to occur, and the action of the accumulator is not an exception to this rule. The proportion of loss generally varies with the conditions under which the transformation is effected, and in the case of the accumulator depends mainly upon the rate of charge and discharge. If these double transformations are conducted slowly the loss may be nearly inappreciable, but at the higher rates which are frequently demanded in practice the efficiency is proportionately reduced. The fact of the existence of this loss clearly indicates that the direct production and consumption of electricity must always be less expensive, both in original outlay and cost of production, than its subsequent use through the medium of accumulators; unless, indeed, there are other modifying conditions which overbalance the additional cost of accumulators and offset their maintenance. That such conditions do exist in many branches of the electric lighting industry can be readily demonstrated, and it may likewise be shown that the use of accumulators as auxiliaries to many existing lighting plants would insure a marked reduction in their running expenses. While it would be absurd to assert in a general way that the accumulator is a superior substitute for all direct lighting systems, and justly expose the views of such a claimant to merited condemnation, it would display equal ignorance to deny that the modern accumulator is a valuable adjunct to the art of electric lighting.

To whatever service accumulators may be applied, however secondary their function in the installation of which they form a part, a nice attention to every detail of their equipment is essential to successful operation. Not the least important part of every accumulator installation is that which pertains to the proper regulation of the quantity and pressure of the current during charge and discharge. This portion, simple as it is, embraces novel and distinct features peculiar to the system, the details of which have been gradually developed as practical experience has shown to be necessary; just as the higher perfection of any art is always reached by a gradual process. Physical apparatus should, of course, be selected with reference to the particular service which it is destined to perform, and it would be folly to attempt to accomplish by means of accumulators results which could be produced to better advantage by other means. It is necessary, therefore, that the applications of accumulators should be undertaken in this spirit by those who are competent to discriminate, as, otherwise, the results accomplished may prove to be as detrimental as they might have been beneficial. If accumulators are intelligently utilized to meet those conditions to which they are by their nature adapted, if they are properly installed with reference to regulation, and faithfully maintained in accordance with the instructions of the manufacturers, they will be found as serviceable and reliable as any other class of electrical apparatus. In the matter of maintenance, accumulators probably require less supervision and attention than is commonly bestowed upon steam boilers, engines and dynamos, or even upon primary batteries, and yet frequent inspection, and proper attention when they do require it, is unquestionably demanded. Neglect of this requirement, like a failure to keep water in a boiler or oil on a crank pin, would very likely result in a serious injury to the plant.

The place of accumulators in electric lighting is a broad one, and it will be sufficient to mention in a general way a few of the conditions ordinarily existing in both central station and isolated incandescent plants, in order to indicate it. It is an undisputed fact that the economy of a given steam power plant is a maximum when the load is a maximum, and that the pounds of coal per horse-power increase as the power decreases. It follows from this that a direct lighting plant can only be operated at its maximum economy when running at its maximum capacity. From what has already been said regarding the infallible certainty of loss resulting from any form of conversion of energy, it is evident that if the load were equal to the capacity of a plant for 24 hours each day no system of conversion could compete in point of economy with one which effected the direct production and use of the current. There is an exception even to this general statement, however, when one or more groups of lamps are located at such a great distance from the source of power, that the interest on the cost of conductors together with the cost of the energy wasted in them, becomes of serious importance; not to mention the increased difficulties of regulation. In cases of this character, the value of the accumulator as an auxiliary to a direct incandescent system becomes obvious. The cells may be located directly at the centres of consumption and charged by a moderate current at high pressure over a small conductor. They may be charged during the hours of light load and discharged as required; the whole charging current, in addition to the current of the batteries, being available on the lamp circuits, during the period of maximum load, if it should be so desired. Often the interest on the cost of such an accumulator installation plus the cost of the energy lost in conversion of current, is much less than the loss by the direct system as previously specified. Another and vastly important consideration in favor of the accumulators is that during the 10 or 12 hours of each day when the consumption of current is so small that a station can only be operated at a loss, the power could be shut off entirely and the accumulators resorted to for the current required during that period.

As a matter of fact, the ideal condition of a continuous maximum load, as assumed above, nowhere exists in practice. The actual load curves for stations of similar capacity throughout the country differ not only in respect to the duration of the maximum period, but likewise in the hours

during which the light and heavy loads occur, according to the character of the lighting. It is nevertheless true that they all show a remarkable similarity in the variation of current consumption, and all the 24 hour stations, particularly the smaller ones, require but a very small portion of the capacity of the plant for the greater part of the day. For this reason, many of the smaller stations cannot be profitably operated for more than 12 hours a day, and customers are therefore unable to obtain the light for the remainder of the 24 hours, the system being thereby deprived of much of its value to many consumers.

Here again the utility of the accumulator for tiding over these costly periods of light loads become apparent. It is evident that any ordinary station running for 12 hours a day, more or less, is not likely to have an output approaching its capacity for more than two hours at the longest, while for the greater part of the time it will be much below it. Why should not such a station be operated during that period of 12 hours at somewhere near its full capacity, and, therefore, under the most economical conditions for the power produced, and utilize the excess of current to charge a sufficient number of accumulators to maintain the lighter load during the remainder of the day?

This is the legitimate work of accumulators, and when they are properly installed and maintained to meet such conditions, the class of small stations referred to will be enabled to supply satisfactory light for 24 hours a day at moderate cost, while the larger stations may greatly reduce their running expenses and at the same time maintain the efficiency of their service.

For a certain class of central station work the accumulator has a field of its own, viz.: the lighting of a district in which the consumers are scattered to such an extent as to make the cost of distribution and regulation prohibitory to any multiple arc system. In cases of this sort the accumulators are, of course, located at small centres of consumption, in such numbers as to meet the requirements. Unoccupied cellars and lofts may be obtained for the accomodation of the cells at a nominal rent, and a single charging circuit may be arranged to take in all of these sub-stations.

Still another application of accumulators has met with considerable favor in some of the smaller towns already operating arc systems. In stations of this character it is not unusual to find that the power plant is only equal in capacity to the arc lamps in use, and while the owners would be glad to be able to supply a limited number of incandescent lights, they object to incurring the outlay for additional boiler and engine capacity. To meet conditions of this kind a sufficient number of cells are installed where required on the series system, and charged by the regular arc dynamo during the day. When the lighting hour arrives the dynamo is changed to the arc circuit and the accumulators then left to take care of the incandescents.

Again, there is no difficulty about installing accumulators on ordinary arc circuits, and this method offers in fact the only satisfactory solution of the problem of operating incandescent lamps on arc circuits. The failure of one or more of the incandescents does not subject the remainder to any excessive strain, and no cut-outs or other automatic devices are required. Moreover, the fluctuations of the arc current are largely compensated by the battery.

Whatever advantages may be gained by the use of accumulators as auxiliaries to central station work, they will prove even more useful and economical when applied to any kind of isolated plant. Indeed, for the latter work, they are usually indispensable. Such plants are generally installed where the necessary steam power is already available, although occasionally the whole generating plant is provided especially for the purpose. In either case the major portion of the lights are only required within a period of ten hours or less, although there are very few instances in which it would not be desirable to the owners to have a limited number of lights for the whole 24 hours, if it were not for the proportionately greater expense entailed by the operation of the plant for that length of time. Now it can be shown that in most plants of this character the same general load curves obtain that have been found to prevail, as already indicated, in central station supply, and it is evident, therefore, that for such plants as are ordinarily operated for from eight to ten hours a day, there would be surplus capacity for a sufficient length of time each day to charge enough accumulators to carry the light load for the remainder of the 24 hours. Under such circumstances the total capacity of the plant could also be increased in case of necessity, by allowing the accumulators to discharge into the lamp circuit at the same time that the dynamos were delivering their maximum output. As it frequently happens that a large isolated plant will not require anywhere near its full quota of lamps at any one time, and yet must have the total current capacity available in the event that it should be wanted, this flexibility of the accumulator system permits of the installation of a much smaller dynamo plant than would otherwise be required, the saving thus made in first cost going a great way towards paying for the accumulators themselves.

As in the case of the central station auxiliary accumulators, already cited, their use in isolated plants enables the power plant to be operated at its maximum efficiency during its running time, and, while supplying light for 24 hours entails only an ordinary day's labor on the regular staff.

As a means of utilizing variable or intermittent power, such as that of waterfalls or windmills, in the production of electric light, the accumulator can hardly be said to have a rival.

The operation of a plant composed wholly or partly of accumulators demands a certain amount of hand regulation, as is practically the case to-day in every direct system. Convenient and reliable apparatus for this purpose is provided, and nothing is lacking in this respect to insure a uniform pressure at the lamps.

The several accumulator systems are, however, more susceptible to various methods of automatic regulation than perhaps any system involving the continuous running of dynamos, and while the supply of automatic devices is not fully complete at present, the increasing use of accumulators will undoubtedly create the demand which will bring them forth in due time.

A NEW SYSTEM OF MULTIPLEX TELEGRAPHY.[1]

BY LIEUTENANT F. JARVIS PATTEN, U. S. A.

THE paper this evening has a single object, its purpose being to describe the salient features of a system of multiplex transmission by telegraph, and as the system is still in the experimental stage, I shall have more to say concerning devices thus far used wherein practical results have come near to the indications of theory, than as to the actual possibilities of the system in use. The general subject is so familiar to all present that a review of the different methods of multiplex transmission is scarcely necessary. Suffice it to say that the system under consideration falls under the general class of synchronous multiplex telegraphs which depend for their operation upon the absolute or approximately uniform rate of movement of similar apparatus placed at the different stations of a line.

In the interest of those present who may not be familiar with the fundamental principle underlying all systems of multiplex transmission, I will give a brief description which will be understood by reference to figure 11. A line wire is shown connecting two distant points, at each end of which is placed a machine which carries a revolving brush or trailer, which is caused by some form of mechanism to

1. Read before the American Institute of Electrical Engineers, February 12, 1889.

sweep over a circular table of contacts ; this is sub-divided, as shown, into a convenient number of segments insulated from each other. Each of these segments is connected to a branch circuit, which includes all the necessary instruments for a single operator sending or receiving. If we consider the trailer motionless and resting on, say, the segment No. 1, then the two operators at the end of the line would each evidently find the main line connected to his sending and receiving apparatus for the time being, and if the trailer remained in the position shown, they could hold uninterrupted communication with each other. If, now, the trailers were moved to the segments No. 2, in each distributor, then operators No. 2 at each end would have the line. It will now be understood that if by any means the trailers could be revolved uniformly around the circle the line would be given in turn to each of a number of operators in succession. Evidently it would be feasible to move the trailers slowly from one segment to the next and so give the line in turn to any number of operators connected, in the manner described, to the main line.

Early attempts at multiplex transmission did not go farther than this. The line was given slowly first to one and then to another operator, the time that each in turn could hold communication being indicated by a common metronome. Later attempts went farther than this, the idea being to make the trailers revolve at a high rate of speed, moving in fact, so fast, that each operator in turn is connected to the line so rapidly that he is practically unaware that the line has ever been taken from his circuit. It is easy to see that this would not require a very high rate of speed. If it be assumed that the operator can make the shortest signal with his key in one-fifth of a second, it only becomes necessary to move the trailers at a speed of more than five revolutions in a second, when it would evidently be impossible for any of the operators to close a key without having the line during this interval connected to his branch circuit. In order that the signal sent by any operator shall reach the corresponding operator at the other end of the line, it becomes necessary, of course, that the trailer at the two stations should be on the same identical segments at the same instant of time. The solution of this problem will then consist in causing the trailers, however far apart, to move with absolute uniformity and precision. If this can be done at a sufficiently high rate of speed then a single wire may be given in rapid succession to a number of operators at each end, and all can simultaneously communicate over the single wire without interruption from or interference with each other.

Such a system has for its object the utilization of all the currents which in a given unit of time can be distinctly transmitted over a single wire. If it is assumed that in average Morse transmission five pulsations of current or makes and breaks of the circuit occur in every second, then if n represent the number of separate currents that can be made to succeed each other during this interval of time, $\frac{n}{5}$ will represent theoretically the number of receivers or operators that can work the same wire at the same time.

Any system based upon the foregoing theoretical consideration, which consists practically in giving the line for a brief interval of time to a number of operators in rapid succession, rests fundamentally upon the fact that the identical revolutions in the same period of time of certain parts of the apparatus at different stations can be maintained continuously, in other words, a perfect synchronizing device of some sort must be the fundamental starting point without which any such system will remain what a noted English scientist has aptly described as a "mere figment of the intellect."

In the literature of the telegraph, already large, synchronizing devices are common, and in the books their operativeness is generally taken for granted. All such devices, with a single exception that occurs to me, are founded upon the isochronous motion of some mechanism which, under the operation of natural forces, has a fixed rate of movement, and preserving this motion unvaried so long as these forces are acting freely. The pendulum and the tuning fork perform their oscillations of great or small amplitude in the same period of time ; their rate of movement is, therefore, described as being *isochronous.* Two such exactly similar devices while in motion, therefore, should be in *synchronism* with each other ; but all these devices once set in motion immediately tend to a state of rest, and it becomes necessary to apply constantly some extraneous force to keep them in continued operation ; they must continually receive an intermittent impulse to prevent them from coming to a state of rest. The natural rate of movement of the apparatus, which is alone the result of the uninterrupted action of the forces in the system, is thus made subject to a slight but constant disturbing effort.

In view of these considerations which have been expressed in the most general terms, it has been my endeavor to perfect a synchronizing device that should be independent of the uniform rate of motion of any part, the general statement of the problem being to devise apparatus which shall move in unison with each other at a variable instead of at a constant rate of speed. Recent electrical inventions point clearly to an ultimate solution of this problem, if it has not already been achieved. A pertinent illustration of this fact is found in the common speaking telephone, so common that variable synchronism is already in daily use among those who regard matters electrical as full of mystery. In this apparatus the diaphragm of the receiving instrument moves in perfect synchronism with that of the transmitter, and it seems by no means an exaggerated comparison to regard the receiver as an alternating current motor moving in perfect unison with the changes of potential in the generator and the line circuit. My experiments in this field were first directed to the application of this peculiar relation of the alternating current generator and motor to a synchronizing device only to reach the conclusion, however, that it could not be made operative on a circuit of any considerable length.

Further experiments led to a simpler solution of the problem involving few uncertain elements.

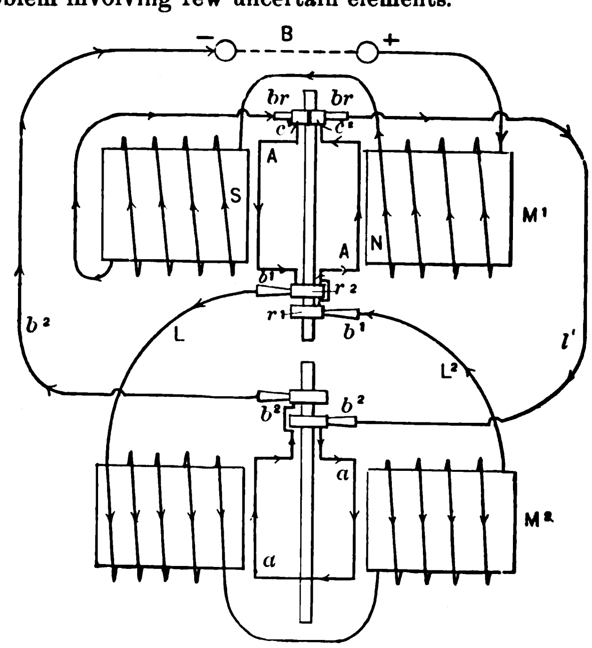

FIG. 1.

I had constructed two ordinary direct current motors of the simplest form, an ordinary two-pole field and single coil armature conveniently arranged for use as either direct or alternating current machines. The armature circuits were connected at one end to an ordinary two-part commutator and at the other to two

insulated ring contacts. They are shown by a simple diagram in figure 1, where both are connected in a single circuit. The armature of the machine M^1 was normally open at the ring contacts, and could be closed either by connecting the ring or through an external circuit. Such a circuit was made to include the field coils of the machine M^2, and the armature of this machine was connected in the direct current circuit from the poles of the battery. Thus connected, the two machines moved as one; the machine M^2 following all the fluctuations of speed in the machine M^1, as if their armatures were carried by the same shaft, the speed being varied between wide limits. To convert this mechanism into a synchronizing device in

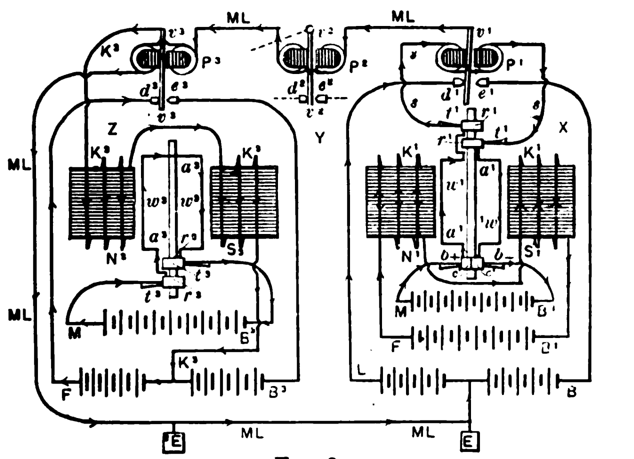

FIG. 2.

such a way that the machines could be placed at a great distance from each other was another step. As there was evidently an alternating current in the external loop connected to the armature of the first machine, the reversals of current in this circuit must correspond in time to the half revolutions of the armature of this machine, and an ordinary polarized relay connected in the loop would vibrate in unison with the half revolutions of the armature in the machine M^1. The second machine could therefore be made operative at a distance by simply connecting another relay in an independent line circuit and causing the latter to reverse the current in the second machine. This arrangement, which constitutes the fundamental synchronizing device is shown in figure 2. Here the first machine placed at station X has a polarized relay connected in the external armature circuit, and the relay vibrates in response to the

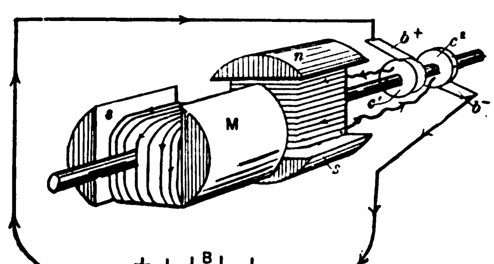

FIG. 3.

reversals of current in the armature of this machine, which correspond accurately to the half revolution of the machine at X. A line circuit extends from the fixed point of the relay vibrator to the distant station Z, where it includes the coils of another relay and returns to the middle point of the line battery L B at X, the opposite poles of which are connected to the contact stop of the relay at this station. From these connections it results that any relays in the line circuit will be actuated by reversed currents in unison with the half revolutions of the machine at X. At any distant station, as the one shown at Z, another machine has its field coils connected as follows: One terminal to the fixed point of the relay and the other to the middle point of a local battery, the opposite poles of which are connected to the contact stops of this relay, the armature of this machine being connected through ring contacts and brushes to an independent source of direct current. Connected in this manner, the two machines still move in perfect unison, even at variable speeds, though separated from each other by any line resistance through which a polarized relay can be made to act. With a single coil armature the driven machine is at times quite erratic, as it can evidently move in either direction, and I have seen such machines reverse instantly at a speed of several hundred revolutions a min

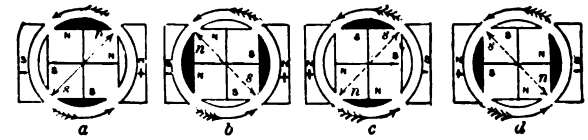

FIG. 4.

ute, and go apparently as fast in the opposite direction, and this even when provided with a fly-wheel of moderate weight.

This difficulty may be overcome in a variety of ways; an effective one is shown in figure 3, which represents a form now given to the armature of the driven machine; it has two coils in series connection, but wound with their poles at right angles to each other. This armature, being placed in a single field, I had supposed would move at only half of the speed of the first machine; but, on the contrary, the synchronism was perfect, the motion was continuous in direction and it has never been known to reverse. The analysis of its action is shown in figure 4, where the armature is represented in the four successive quadrants of a single revolution, the black and the white pole pieces representing the ends of the two coils in their different positions. The dotted lines indicate the position of a pair of resultant poles which must lie diagonally between the actual poles; this diagonal line represents the resultant polarity of the armature, and it is evident that neither of

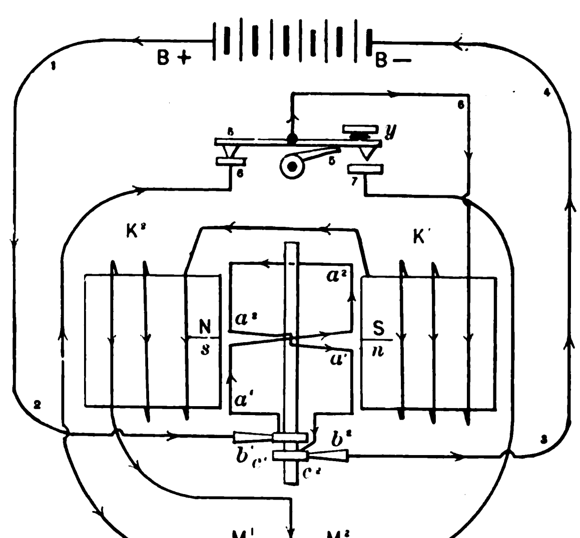

FIG. 5.

its actual poles could be in a position of stable equilibrium while in line with the poles of the field; the resultant armature pole is therefore made to follow a changing field that moves through 180 degrees at each reversal of the current.

Figure 5 illustrates an experiment made in determining

a suitable form of armature. A two-point key was used to reverse the field intermittently, the armature being supplied with an independent direct current. Even with this irregular alternation of the current the motion was still continuous. Another method of preserving absolutely steady synchronism is shown in the sketch figure 6. In consists in providing the driven machine with a single coil armature and a multipolar field; thus arranged the armature passes through a smaller arc of the entire circle at each reversal

FIG. 6.

of the field; but while the motion is steady it has the evi dent disadvantage that so high a speed cannot be obtained with the same number of reversals in a given time.

Such are the main features of the synchronizing device. There are numerous details which cannot be treated within the limits of a single paper. The uniform motion of distant machines is secured at rates of speed that may vary within considerable limits, and synchronism is maintained independently of the isochronous motion of any device or moving part, all the machines moving in unison with a govern-

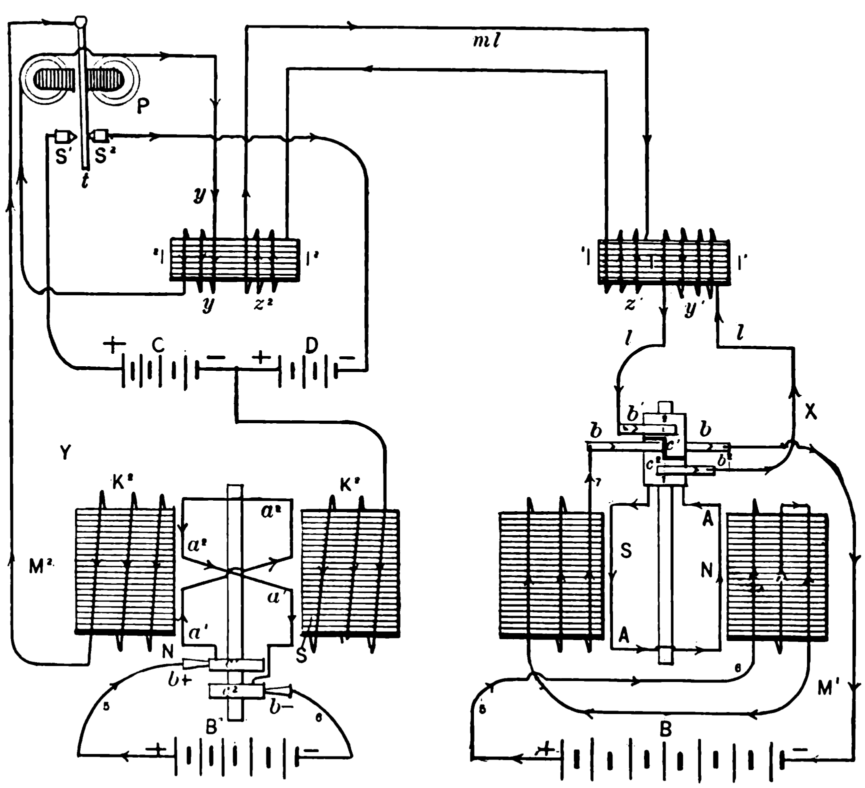

FIG. 7.

ing motor which sets the pace for all the rest. The controlling machine may evidently be any form of direct current motor carrying a revolving pole changer.

A practically constant speed is, of course, necessary in any application of this device to the telegraph, but as an illustration of the variable synchronism it may be stated that in a continuous run of 25 hours the speed of three machines, connected by a single line circuit, has varied uniformly between 100 and 1,000 revolutions per minute. Figure 7 illustrates a modification of the original system in which induced currents of high E. M. F. are used as synchronizing currents. The armature loop of the governing machine is connected to the primary of an induction coil, the secondary to the line circuit at distant stations, the impulses are reconverted and caused to actuate a polarized relay as before.

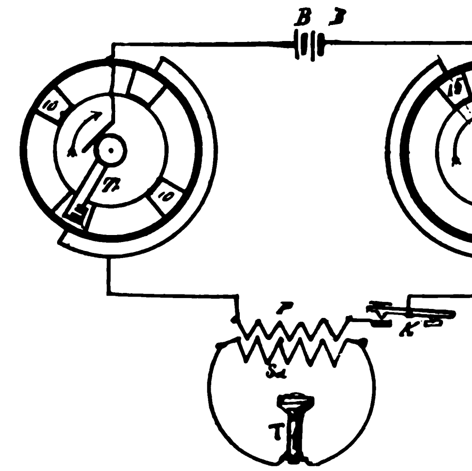

FIG. 8.

A simple experiment made to determine the accuracy of the synchronism will be explained, as it led directly to a separate application of the systems to the transmission of signals. The connections are shown in figure 8. From the battery B a line extends to the spindle of the two machines, each provided with segmental distributors of 48 parts. From one such segment in the machine M^1 a wire was taken to a segment of the other machine, the primary of an induction coil and a key being connected in this line; the secondary of the coil was connected, as shown, to an ordinary telephone receiver. If the machines were moving in unison the circuit of the primary would be completed whenever the revolving trailers were simultaneously upon the connected segments in the two machines, and the key was closed. If either trailer were slightly in advance of, or behind, the other, there could be no primary circuit formed on closing the key, no induced current, and no sound in the telephone. The machines were driven at variable speeds, and the wire at one machine was moved from one segmentto another, until the particular one was found that corresponded to the one selected in the first machine; the telephone then responded accurately to every revolution, thus proving the synchronism perfect within less than the breadth of a single segment. Other wires were then connected to other segments with a like effect.

A singular and unexpected result was deduced from this experiment. Evidently the machine M^2 might start into synchronism at any point of the circumference, the trailers making any angle with each other, as the one shown in the diagram. A revolving switch had been provided, which was so arranged that by turning it a wire could be moved from one segment to another, and so adjust the circuits independently of the relative positions of the trailers. The machines were repeatedly stopped and started again, but

came again into synchronism always at the same point, the wires never requiring any adjustment, establishing clearly the singular fact that the driven machine always went into synchronism at the same point, and could, therefore, be made to start in at any point of the distributor by

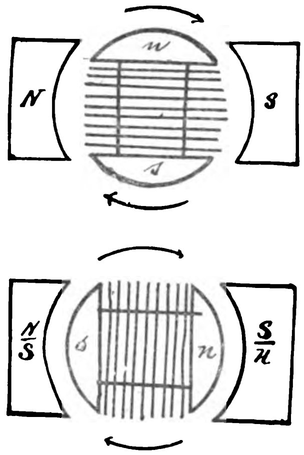

FIG. 9.

a proper adjustment of the trailer on the spindle. The reason for this may be found by considering the relation of the forces as expressed in the diagram figure 9. Here

X and Y are connected to the line M L, as shown in figure 2. The synchronizing current is constantly maintained upon the line, and is made to serve also for transmission of signals. It will also be observed that as the armature of the relay at X puts opposite halves of the line battery to earth alternately at each half revolution of the machine at X, one-half of the circumference of the segmental distributor corresponds to the transmission of positive and the other to the transmission of negative currents to line. Thus while the trailer is sweeping over one-half of the distributor, one part of the line battery L B is connected to line and earth, and while traversing the other half of the distributor the other part of the battery will be in circuit, each in turn sending a succession of impulses of opposite polarity. Some arbitrary line as Q^1 U^1 may, therefore, be drawn diametrically across the distributor at X, and on one side of this line positive, and on the other negative, currents will be sent to the line wire, and by making the distributor movable about its axis the line Q^1 U^1 may be made to fall within the broad spaces $E+E-$. The distributor is composed of two parts, one designated $E+$, and $E-$ is connected directly to earth; the other consists of a series of insulated segments, 1, 2, 3, etc., in opposite quadrants of the distributor. Whenever the trailer is on the parts $E+$, $E-$, the battery has a free path to earth and line through the trailer Tr^1. The insulated segments are connected to the local branches in pairs, each local branch having at least two such segments diametrically placed in opposite

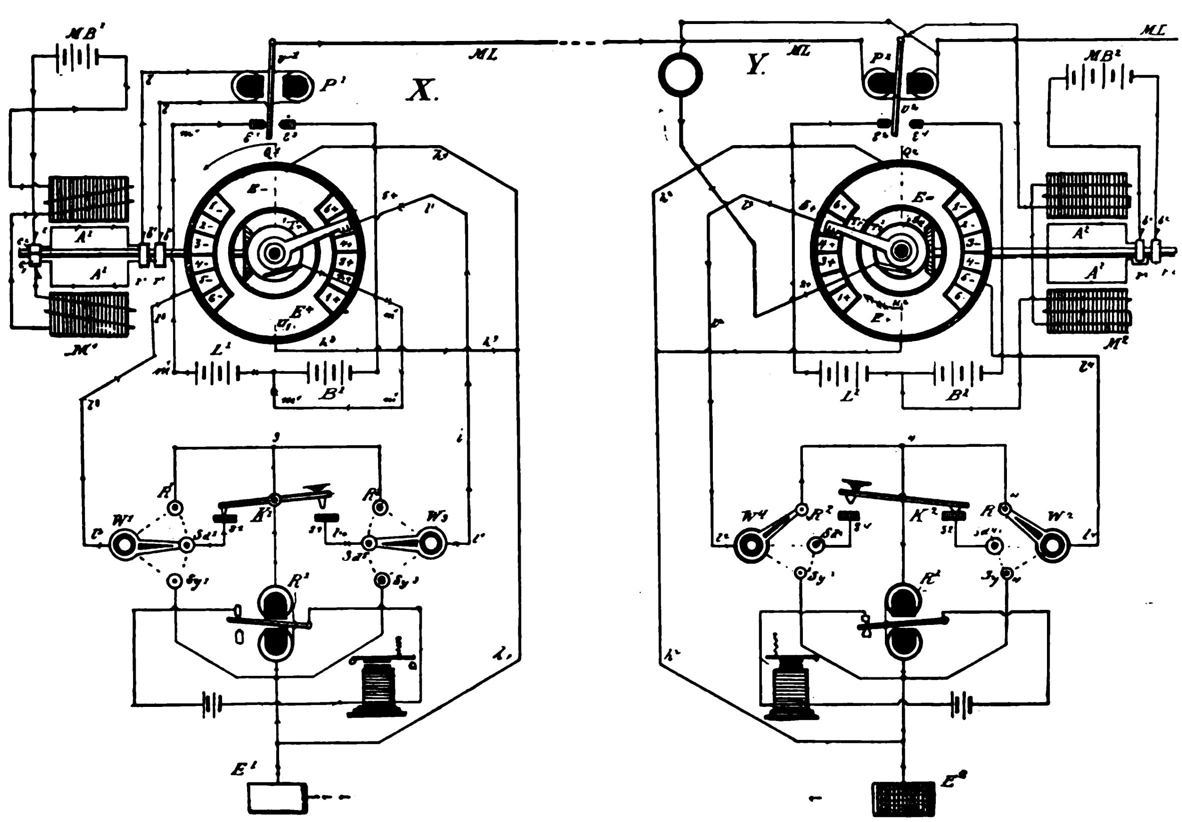

FIG. 10.

the same machine is shown with the armature in two positions, differing by 90°; the first is a position of maximum effort, while the second is a minimum, as the field poles are changing to the opposite designation indicated by the lower letters. As the machines are provided with fly wheels of considerable weight, the point of maximum effort shown in the upper diagram is the one at which the machines most readily come into synchronism with each other, being the point of least opposed mechanical resistance. In figure 10 is shown the simplest adaptation of the synchronizing device to a system of telegraphic transmission. The motors

halves of the distributor. The connections and instruments in circuit are alike for all the branches, and are, therefore, shown in detail for only one.

Each branch—say that of operator No. 5—has a double line to earth taken from opposite halves of the distributor, as those shown at 5 + and 5 —. These branches are connected to a three-point switch W^1 and W^3, which may be turned to R^1 and R^3 for receiving, or to S^1 and S^2 for sending, thus throwing the key in circuit, or to sy^1 and sy^2 for synchronizing, thus leaving the sending and receiving apparatus out of circuit. An ordinary reversing key is used,

the relay circuit being connected to its middle point. The drawing represents station X sending and Y receiving. Thus, if the key be depressed, as at Y, so that its front contact puts the line to earth, intermittent pulsations of one polarity will go to line, corresponding to the contacts made by the trailer with the segment pertaining to this branch on the right hand side of the distributor at X, while the negative currents, corresponding to the left hand half of the distributor, will be cut out, and the corresponding relay at both stations will be actuated by currents of constant polarity. If, now, the key be reversed, the trailer, on reaching the opposite segment, 5 —, will send an opposite current to line and earth, causing the polarized relay to reverse in accordance with the motions at the key; hence signaling may be effected with a sounder connected in a local circuit as shown. Thus, if the key were closed at both the front and back contacts at the same time, the receiving relays would all vibrate in unison with the synchronizing relay in the line circuit, and transmission is effected by cutting out all the positive or all the negative impulses, according to the position of the key, whether on its front or back contact. With a slow speed the contacts connecting any branch to the main line must of course be increased to insure certainty of action; but with a sufficiently high speed few contacts will be required. In the foregoing system the synchronizing current, which is only used as such at two points during each revolution, is made to answer for signaling purposes also.

There are, of course, numerous details incident to such a system that cannot be dealt with in a superficial description. Each operator's circuit being made up with a number of rapid contacts with the main line, each one of the ordinary Morse characters is necessarily made up of a number of pulsations of current, and the serious problem has been to construct a relay that would respond to these broken currents. A single polarized relay has a tendency to leave its contact during the breaks. A number of devices have been made to correct this. One such device is a sort of locking relay. From the opposite segments on the distributor the branch circuits go as before to the contacts of a two-point key, but each through the coils of a separate relay, either of which has its armature attracted according to the position of the key, Either armature on being drawn up becomes locked by an auxiliary magnet, and held in this position so long as the armature of the other relay is against the back stop through which the locking circuit is closed. On reversing the key the second armature is momentarily drawn up, and is locked in the same manner by the armature of the first, which is then released. Numerous other devices of a similar character have been used, which cannot be explained in this paper. Figure 11 shows by a diagram of circuits a modification of the system of single wire transmission, in which superposed currents of high tension are used to actuate the receiving apparatus, thus making it independent of the synchronizing current. The key is so arranged as to open and close the primary of an induction coil, the secondary of which is connected to line. A telephone or similar receiving apparatus, arranged to respond to currents of high E. M. F., is connected with a receiving circuit instead of the relays. With such a system of transmission a higher order of multiplex transmission can be obtained than with ordinary receiving apparatus; and it requires so little current to actuate these instruments that each operator can work a circuit with a far less number of segments. As the trailer makes contact with any particular segment there will be, of course, two currents sent, due to the make and the break. In figure 12 is shown an arrangement by which the first of these is cut out. The primary of the induction coil, connected through a separate trailer and series of segments, is closed by the key before the trailer connected to the line circuit has reached its segment. The induced current due to the break only is then transmitted to line. This device is shown in figure 12, and, as there indicated, it has also been made to work polarized relays suitably wound for these high tension currents.

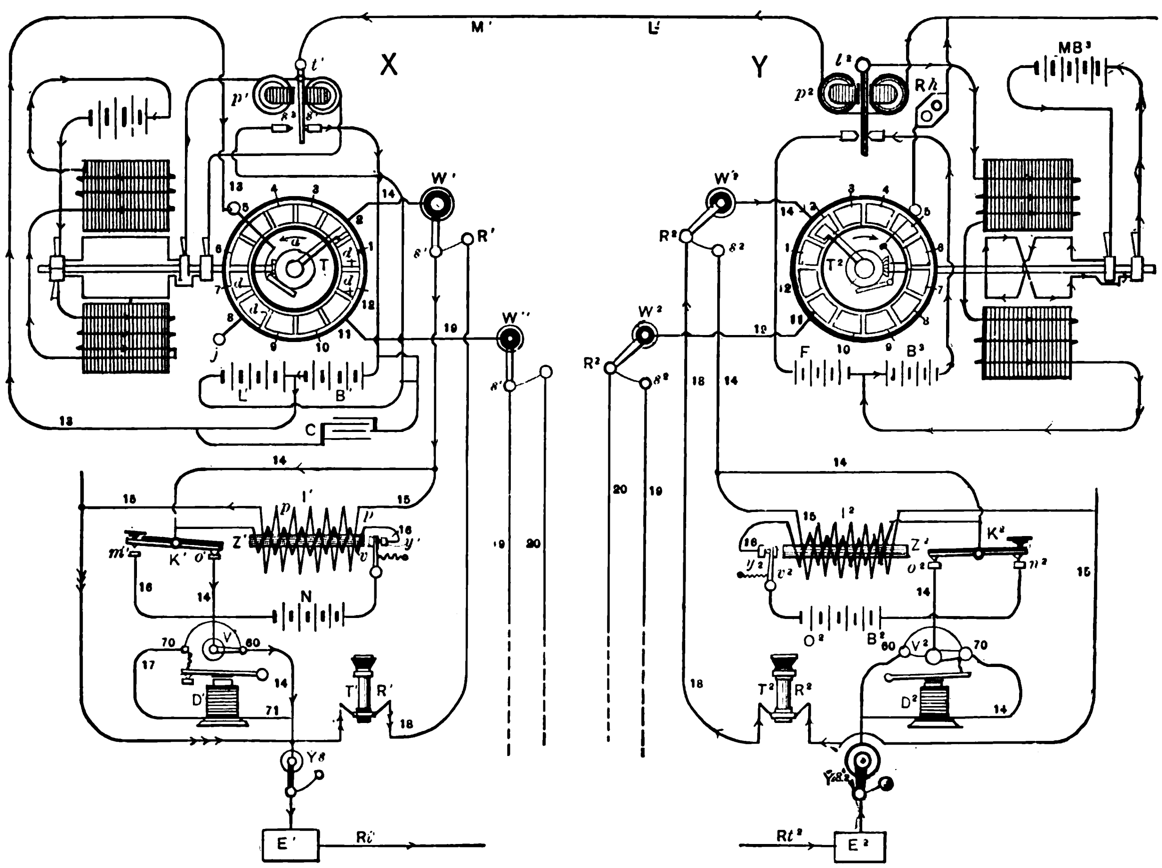

FIG. 11.

The general subject as a system of telegraphy will be recognized as a rather extensive one for a single paper. I have given the details of a few of the more decisive experiments that have been made, and I have confined the paper to what has actually been accomplished. With reference to practical results on a line test I shall have more to say at a later day. A technical paper, at its best, is uninteresting, and the present one is already long. In closing, I will answer a pertinent question that may occur to many: Of what use is a system of multiplex telegraphy?

The answer is this: We live in an age of industrial advancement. People are no longer satisfied with what is good enough. They want the best. The best rail for roads must be made of steel, and, this fact once established,

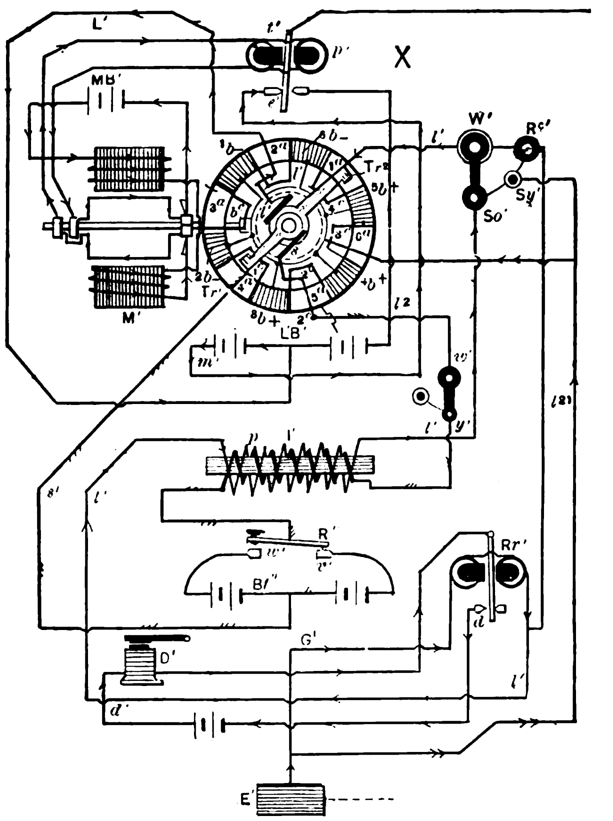

FIG. 12.

iron was no longer suited to the requirements of travel, and iron roads have been turned into steel ones. The steel rails bear the same relation to iron in the systems of transportation that the copper wire does to the iron one in systems of telegraphic communication. The higher rate and more reliable service required demanding already, in a large degree, the substitution of copper for iron wires on the main lines of business. With a good copper wire and a reliable system of multiplex transmission, a single wire from New York to our principal cities would meet all the requirements of business, and it is no exaggeration to say that with these conditions given the existing system of intercommunication by the telegraph could be duplicated at a cost of one-tenth the present amount of capital invested by either the government or private enterprises. That is what copper wire and multiplex telegraphy mean, and it is doubtless the reason why so many find the subject worthy of their best endeavors.

.... SPECIAL dynamos are now made which will, with an expenditure of 100 h. p., precipitate 18 tons of copper per week. The impure metal is made to form the anode in a bath of sulphate of copper, the metal being deposited in a pure form on a thin copper cathode.—*W. H. Preece.*

ELECTRICAL ENERGY DIRECTLY FROM SOLAR RADIATION.

BY PROFESSOR I. THORNTON OSMOND.

THE dynamo has an efficiency which is above complaint. Its fatal defect is its necessary connection with the steam engine. The steam engine has an efficiency which is very objectionably low, and, in the nature of things, this is absolutely irremediable. As the work agent of the world, the steam engine, inestimably great as its service has been, is no longer tolerable, except of necessity, until its successor arrives. Instead of thermal energy, electrical energy is to do the work of the world. This requires a simple and cheap means of unlimited electrical supply by apparatus or processes entirely independent of the steam engine (or any thermic engine) and the dynamo.

The cheapest supply of energy, the most universal and the most unlimited, is from the very source, the solar radiation. What is required, then, is an inexpensive apparatus and process for obtaining this energy in electric currents; call it a *helierg*. This, with a fairly perfected storage apparatus, science and invention must give to the world before long.

In considering possible methods of obtaining electrical current directly from solar energy, in November of 1886 I was led to study Faraday's discovery of the rotation of the plane of polarization of light by magnetic forces, and Maxwell's electro-magnetic theory of light. It seemed to me probable that this might be the way to accomplish, or to find how to accomplish, the desired result. Should not *the rotation of the plane of polarization produce magnetism?* Faraday certainly expected that electricity would be obtained in some way directly from light. "What the possible effect of the force may be in the earth as a whole or in magnets, or in relation to the sun, and *what may be the best means of causing light to evolve electricity and magnetism*, are thoughts continually pressing upon the mind * * *." Exp. Res., xix series, 2,242.

Soon afterward I devised a series of experiments for testing this matter, but I was prevented from doing more than sketch some apparatus until the ensuing spring. I then performed some of the following experiments, and others of them later.

I constructed a polarizer of a bundle of thin sheets of glass, set in a tube at an angle of 35° 25′ with the axis, giving a transmitted polarized beam about five centimeters in diameter. The tube was rotated by a belt from a wheel, a beam of sunlight being sent through it from a rude heliostat.

Three coils, from 18 to 63 cm. long, with different amounts of wire, and of different internal diameter, were fitted with soft iron tubular cores, with glass plates covering the ends. These were for holding vacuum, air, liquids, etc., to be traversed by the beam, whose plane of polarization was being rotated by the polarizer.

The following are some of my series of experiments:—

(*a*) Try whether an astatic needle, silk fibre suspension, placed axially in the rotating beam, is deflected; the same, placed at right angles to the beam.

(*b*) Try, with astatic galvanometer, cutting the rotating beam variously by a loop of wire connected to galvanometer.

(*c*) Try several meters of wire lying in (along) the rotating beam, with the ends connected through the astatic galvanometer.

(*d*) Try several meters of wire, as in (*c*), but with ends attached to quadrant electrometer.

(*e*) As (*c*) and (*d*), but using an electro-dynamometer to see whether an alternating current is produced.

(*f*, *g* and *h*) Try passing the rotating beam through the different coils, with air, water, carbon disulphide, etc., and using galvanometer, electrometer and electro-dynamometer.

(*i*, *j* and *k*) Try the above with arrangement for alternately admitting and cutting off the beam, either rotating or at rest.

l, *m*, *n*, and some other experiments, I will not at present describe.

(*q*, *r*, *s*) Try a coil of wire wound longitudinally on a bar of iron, 2.2 m. long, 2.5 cm. square, with astatic galvanometer, quadrant electrometer, and dynamometer.

(*t*, *u*, *v*) Try a coil of wire wound longitudinally on a wooden bar, 2.5 m. long and inserted in an iron water pipe, with astatic galvanometer, quadrant electrometer, and dynamometer.

These experiments were made in the second story of a five-story building (above basement), used for dwelling houses, dormitories and general college purposes. The apparatus, except the astatic galvanometer and quadrant electrometer, was very rude. The polarizer is but partial, the means of rotation very inadequate, and the continual jarring of the building renders certainty as to small action of galvanometers, etc., impossible.

The result is, (1) My work proves that there is no opto-magnetic or opto-electric action of sufficient magnitude to be certainly discoverable, with such apparatus and under such conditions as I used, by methods (*a*) to (*k*), inclusive. (2) It is far from disproving such action.

In fact, I believe in two or three of the experiments there was indication of slight electric action.

I hope to have within a year better conditions for work in the Physics building (Pennsylvania State College), now under roof, to reconstruct some of my apparatus with greater efficiency, to add some, and with improved conditions and means to re-try some of these experiments more decisively, and to continue the research by other experiments.

Papers Read Before the National Electric Light Association, Chicago, Feb. 19-21, 1889.

DISRUPTIVE DISCHARGES IN LEAD CABLES.

BY C. H. RUDD.

In coming before the association at this time with the subject named, my principal object is to consider the experiments of A. G. Acheson. An account of these experiments appeared July 7, 1888, and was enlarged upon by Mr. Acheson at your last meeting. The results of the investigations suggested two conclusions :—First, that the static capacity of a cable is a transforming agency by which a passing current might develop a static charge of greater electromotive force than the electromotive force which produces said current ; Second, that a static charge

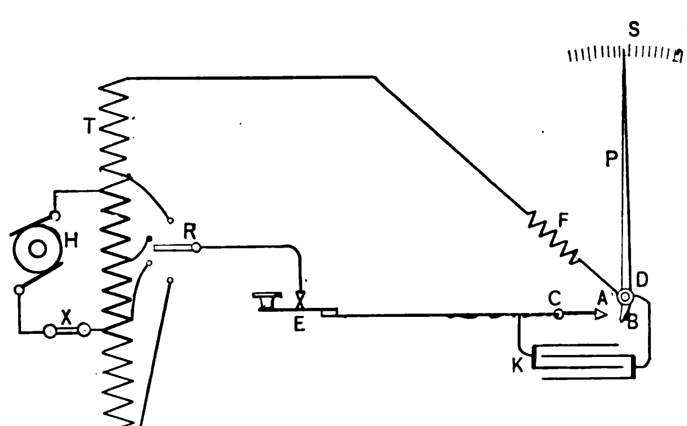

Fig. 1.

will not pass an arc. These conclusions are radical and cannot fail to attract attention. If they are sound they have a most important bearing upon cable service. By virtue of the first conclusion, we would be obliged to largely increase the value of cable insulation, or else put on high pressure protectors of a nature to carry a constant stream of sparks. And we would be obliged to ask, why have we not had a much greater number of burn-outs than we have? By virtue of the second conclusion, the high pressure protectors, if used, would have to go into every section of cable cut off from other sections by lamps. I do not believe these conclusions to be sound, and expect to show that they are not. I question the first because it conflicts with the well-known law that the electromotive force of a static charge cannot exceed the electromotive force of the charging source. This law is as well sustained in daily practice as is Ohm's law. If the results of an experiment point to the overthrow of a long-established principle, the experiment itself will bear inspection.

Let us look at the experiment from which the first-named conclusion was drawn. Figure 1 is an exact copy of Mr. Acheson's first diagram. H is an alternating dynamo. T is a transformer, in which a portion of the wire is used for both primary and secondary. R is a switch to aid in obtaining different degrees of pressure. E is a switch with which to break the secondary circuit. X is a switch with which to break the primary circuit. C and D are posts supporting points A and B. The distance between points A and B is adjusted by means of pointer P and scale S. F is a piece of fusible wire for safety. K is a condenser. Now, let us suppose condenser K to be disconnected for a moment. It was in that form that the first step was taken. We are told that by rupturing the circuit at E, sparks were obtained between A, B, of various lengths according to the position of switch R. This is plainly impossible. To open switch E is but another form of increasing the distance between A, B, and we know that such increase would not cause a spark at A, B. I do not deny that sparks were obtained in the experiment, but I do deny that sparking conditions are shown in this diagram. There are no explanations offered by which the sparking conditions can be understood, and explanations would be valueless in this case, for if the sparks occur in any roundabout way the experiment becomes simply an electrical puzzle without bearing upon the subject under consideration. The investigator seems to assume that everybody will agree that ruptures of circuit and sparks are inseparable. This assumption is without support. When ruptures

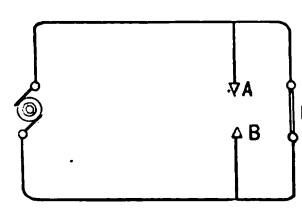

Fig. 2.

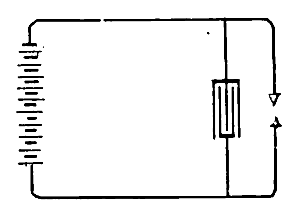

Fig. 3.

produce sparks it is because accompanying conditions are favorable, for instance : If a closed circuit is relieving two points of electrical strain (see points A, B, figure 2) and the circuit should be ruptured, say at E, points A, B would have to bear the strain and a spark might pass between them. We do not find such tendencies to spark in the work shown. From the nature of the investigation it is manifest that the first step in the experiment should have been to produce sparking conditions such that the sparks would depend on pressure only, after which the effect of adding condenser capacity could have been properly observed. Inasmuch, then as the experiment shown to us lacks the vital element necessary to make it demonstrative, every deduction made from said experiment must fall to the ground. The subject under investigation by Mr. Acheson is treated of by Gordon under the head of secondary condensers. A secondary condenser (see figure 3) is said to add to the burning power of a spark. If Mr. Acheson had made a proper series of experiments in the laboratory and had then desired to carry his work over into practical life, he would have first obtained a cable carrying heavy current, the

cable having in it a spot so weak that the direct pressure was able to break through. In such a case he would have sparking points around which he might connect his secondary condenser, and observe its effect upon the burning power of the spark. He would, however, require some sort of electrical microscope with which to make his observations. That any ordinary method of noting the effect of a condenser upon the spark which I have described would be of no value, is manifest when we consider that a condenser of one microfarad charged to a voltage of 2,500 would hold .0025 coulombs. A current of one ampere carries one coulomb per second. As it is, coulombs which determine the destructive power of a spark, it is plain that when direct pressure begins to break through a weak spot in the cable, the addition to its destroying power, which it receives from the condenser capacity of the cable is extremely insignificant. To sum up my position concerning Mr. Acheson's first conclusion, I will say that the static charge in an ordinary cable is a negligible quantity when compared with the regular current flowing, and the electromotive force of said charge cannot be greater than the electromotive force of the current from which it was derived. Therefore, in considering the character and thickness of insulation, we have nothing to take account of but the primary pressure which bears upon the insulation. Mr. Acheson's second conclusion, viz., that a static charge will not pass an arc, virtually declares an arc circuit to

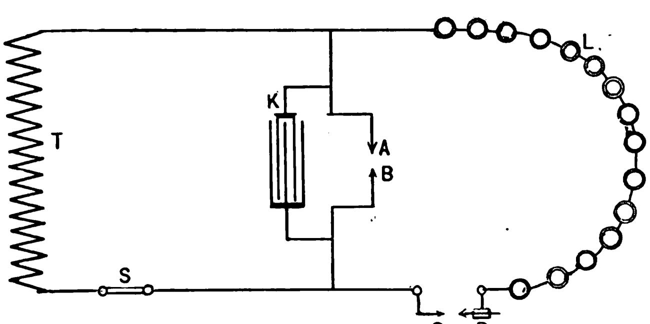

Fig. 4

exist as a number of sections in a sense insulated from each other, and in that connection the statement is made that each separate section comes under separate strain every time that the circuit is shut down. I think that I have already satisfied you that we may hold our old ideas concerning the electromotive force of a static charge, therefore we need not fear that an imprisoned charge would do any more harm than the current did from which it came. If we charge an ordinary condenser from a battery, and the condenser does not break down, we do not apprehend that the condenser will break down when we disconnect the battery. There is in the minds of some people an idea that static electricity when it begins to move produces a current possessing different properties from currents formed by other electricity under the same conditions. This idea is unsupported, and need not be entertained seriously.

But let us see how Mr. Acheson proves that a static charge will not pass an arc. In figure 4, T is a transformer yielding 2,067 volts. S is a break switch, K is a condenser, A, B, sparking points, C, D, adjustable points so arranged as to be readily placed in contact, L a circuit of 20 incandescent lamps in series measuring perhaps 4,000 ohms all told. Mr. Acheson says that when contact was made between C, D, no amount of rupturing circuit at S, could cause a spark at A, B, but when he opened points C, D, and produced an arc there, then rupturing circuit at S, produced a heavy spark at A, B. From this the conclusion is drawn that the arc is an effectual barrier to the passage of static charge. Let us see. If we have an arc burning at C, D, it would expire simultaneously with the arc which would form at S, when S is opened. Therefore, the retardation spoken of by Mr. Acheson was due to the break at C, D, and not to the arc at all, the arc having expired before the observation on retardation was made. To sum up my position as regards the second conclusion it is evident that the arc affords free passage to ordinary currents, and we have nothing to indicate as yet that the arc makes distinction between the static charge in motion and other electricity in motion. It is also evident that the insulation of a cable does not undergo strain at shutting down due to the static charge. Mr. Smith referred at the last meeting to some sparks observed when an arc circuit was shut down. These sparks may be readily ascribed to magnetic discharge from the lamps.

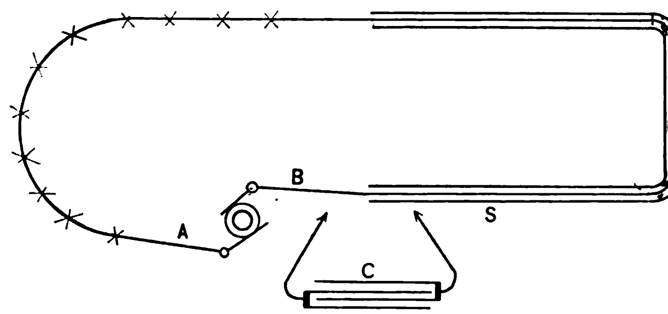

Fig. 5.

I will now speak of an experiment in which I assisted last summer. The experiment is one which Mr. Sunny described before this association in August, 1888 ; 1,000 feet of lead-covered cable was laid out upon an ordinary dry floor. This cable was connected as a loop into a working circuit. When first connected up, condenser C could be strongly charged by placing it in circuit between B and S, figure 5. At first sight it seemed that Mr. Acheson's position was confirmed. An attempt to repeat this experiment on the following day resulted in failure. Another attempt on the third day succeeded. I arrived at this stage of the proceedings. Upon examination I found that different working circuits had been used each day. The leading idea in the experiment was that if a current would create a static charge of a nature unlike said current, the results should be obtainable from any working circuit. When I learned the conditions of the various experiments, I affirmed my belief that the results obtained were of the most commonplace nature, and requested that the steps in the experiment be repeated. This was done. We found that when we put the extra cable into a circuit entirely under cover scarcely a sign of charge could be seen in condenser C, but upon plugging into a circuit exposed to the weather, a definite charge was obtained. We then returned to the covered circuit Results were same as before, viz., no charge. We then put a ground at A. This gave us a strong charge. We then began to observe the polarity of charge, and found that we could reverse the polarity by putting the loop in at A, and the ground at B. This change removed all ideas that the results obtained were out of the ordinary, and let us square down upon the common principles of everyday life. The shield S was a ground of some value, so we concluded that we had been trying to see if we could get a charge out of a working dynamo by connecting a condenser between A and the ground with a ground at B, and again if we would change the polarity of the charge by putting the condenser between B and ground with ground at A, figure 6. A rather simple experiment when stripped of its useless features.

In conclusion, I will say that if disruptive discharges occur in properly insulated cables, we must look for the cause in those sources of high pressure which exist in nature. I do not believe that burn-outs can be ascribed to any one cause, but that each individual case has its own individual cause. In practice we must provide insulation strong enough to meet the daily strain, and suitable devices to prevent the accumulation of charge from outside

sources of greater pressure than the insulation will bear. As yet we have no proof that high pressure protectors are required anywhere outside of the station from which the wires start. Mr. Acheson says that the greater number of grounds or burn-outs occurring on arc light circuits are at the terminals of the lead or at the joints, and says that such a state of things would be naturally caused by the greater density of the static charges at these points. This

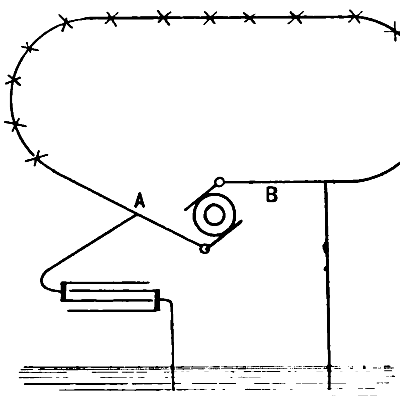

Fig. 6.

statement strikes me as a singular carrying over of ideas obtained in laboratory work with purely static electricity and arbitrarily applying them to entirely different conditions. The natural static charge in a cable, due to the distribution of the working electromotive force of the current in the cable, must necessarily be governed in its distribution by the force from which it originated. The shape of the conductor cannot act in the matter of this kind of static distribution, as the shape of an insulated conductor would act upon a purely static charge. This remark of mine about distribution may not be treated of by any of the men who write books, but I confidently appeal to my hearers for support. As regards burn-outs occurring at terminals and joints, we know that great care is required to make these points equal to the rest of the cable in matter of insulation. I do not see how it can be known that burn-outs at such places are not due to accident in construction or actual neglect on the part of the workmen.

ELECTRIC LIGHT STATIONS AS FIRE RISKS.

BY S. E. BARTON.

(Abstract.)

THROUGH stress of circumstances my paper will be short, but I wish to touch both subjects in a general way.

Insurance companies, like yourselves, sometimes get involved in litigation, and it is my unhappy lot to have been drawn into that unfortunate condition, to the exclusion of almost everything else, for the past two months. I offer this information as a preliminary apology for what may follow.

I cannot refrain in the outset from congratulating myself, and my insurance associates in New England, upon the very cordial relations existing between ourselves and the electric lighting interests, and also upon the very favorable experience the underwriters of New England have met with in having comparatively little loss to pay on account of the electric lighting fire hazard. Nor can I refrain from saying that, as favorable as our experience has been in the past, it is being, and will continue to be, made much more favorable through the good work undertaken, and being carried on through the New England Electric Exchange. Its influence and results tend in the right direction—to the education of those employed in electric lighting pursuits as to what practices and work are safe and what are not, and to the exclusion from such pursuits of any who may, through lack of proper scientific knowledge, be unqualified for the positions they hold.

As a matter of fact, however, I believe that the experience has been, that because men have been required to provide themselves with a license certificate as to their qualification, they have speedily and earnestly set themselves to work to gaining the necessary technical knowledge to qualify them to receive the certificate. It goes without saying, I think, that those men are thereafter more capable in their business, and safer men for all parties concerned than they were before.

We having on the one hand an element so fraught with hazard, and on the other one so easy of control, your duty is obviously to do all you can by your own work to promote and secure safety, and to encourage all feasible plans and efforts of others tending in the same direction. While the plain duty of underwriters in the public interest is, first to hold to a strict line of requirements any of you who may be tempted, through competitive pressure, to depart from what you know are safe practices, the underwriters' duty is not fulfilled until they have indorsed electrical illumination and power by the reduced premium charges that such combined action on the part of electrical and insurance interests is sure to warrant.

The two interests are peculiarly identical. Hand in hand they can accomplish much in reducing the enormous fire waste. Disunited and antagonistic to each other, your work will be slower in development. Competition among yourselves and no restraining supervision on your part will drive you to cheaper construction and maintenance of your work. More fire loss and higher premiums for insurance must inevitably be the result, while the public, still calling for your light because it is good, will be deterred to an injurious degree by reason of the increased insurance rates that will surely follow, such as have already been applied in some cases and threatened in others.

The policy of insurance companies and organizations toward electric lighting or any hazard, in fact, capable of being minimized, should not be "to fit the punishment to the crime," but rather to lessen the crime, or endeavor to. In your case they will be loth to undertake that policy without your co-operation, and can succeed only with it. Without their co-operation, I think you would make but little headway in that direction.

In New England electric lighting is very popular with insurance men, particularly since it has, as applied to some risks, been included in the schedule of "improvements" for which a reduction in tariff is made. The energetic agent in his efforts to scoop in his competitors' pet risks does not fail to recommend the introduction of electric lights as a means of procuring a lower rate and securing the risk to himself. He thereby becomes your solicitor. He goes still further; in many cases he manifests his favor to you and serves his own interests by becoming an investor in your apparatus, and a promoter of your industry. Such a condition of things is but the natural outgrowth of a perfect harmony and co-operation between the two great interests. It ought to exist throughout the land.

By reason of faulty work which crept in during the early stages of electric lighting in Boston, numerous small fires which have occurred there have created a scare among insurance men, causing a threatened increase in rates unless a remedy was applied. The following notice just issued by the Boston Board of Underwriters indicates where they look for relief:—

"At a meeting of the Underwriters' committee, held January 28, 1889, it was voted that on and after May 1, 1889, all electric lighting and wiring companies' men, who are in any way responsible for any of the wiring, running, of dynamos, or care and management of batteries for electric lighting, must hold a license from the New England Electric Exchange. This rule applies to isolated plants

and central stations alike, and is imperative. No exception to it will be made."

Such a rule may seem arbitrary to anyone not in sympathy with the objects sought by the "Exchange" (and there will always be found some objectors to any good movement), but after all I believe it is just the medicine needed for the complaint.

In regard to the electric light generating station, the situation is not a pleasing one to either party. Out of over 200 fire insurance companies doing business in Massachusetts, the electric light station is a prohibited risk with all but about 25 or 30 of them. The reasons for this interdiction are chiefly these: First, because electrical apparatus, and dynamos in particular, have been found to be very susceptible to large and uncertain damage, in cases of small fires; secondly, because generating stations have too frequently been crowded into very hazardous and improper quarters, simply to get floor space and power at the smallest cost, without regard to permanency and ultimate results; lastly, and mainly, because insurance men as a rule, do not understand the nature of the hazard and often fail to get enlightenment from those in charge of stations. Therefore a large majority of the companies adopt the course of all wise underwriters,—they "take the benefit of the doubt" and leave your station risks alone.

Judging from my own observation of the way in which electric light station risks are peddled about to find takers, and the rates that are charged by reason of their being so few takers, I am led to believe that the question of insurance is to many of you an unsatisfactory one. I cannot help thinking that, even with the present condition of stations as fire risks, if the business as a whole were so classified as to show the aggregate premiums on the one side, and the losses and expenses of doing the business on the other, a fair margin of profit would be shown. But no such general classification or account is made, and the experience of those few companies that venture on your risks, if favorable, is carefully kept to themselves, so that others may not be induced to venture.

Perhaps a bureau of the National Electric Light Association might be formed, the purposes of which would be to collect information as to the aggregate premiums paid and losses incurred in central station insurance. If such a labor should demonstrate that a fair profit remained after deducting gross losses and expenses from gross premiums, probably modified rates and a freer acceptance of the risks would follow. If it demonstrated that the present high rates of premium yielded no profit to those companies insuring your plants, then you would be convinced of something radically wrong, and you would have before you a field for investigation and a work of much needed reformation.

Maybe an Electric Light Mutual Fire Insurance Association would solve the question; but such a step should be taken with caution, and should be guided by those well-founded principles and practices that have proved so successful with the Manufacturers' Mutual Fire Insurance companies of New England, and of which C. J. H. Woodbury (well known to many of you) is a prominent officer. No risk should be accepted by such an association until improved to a certain standard as a fire risk, and then regular quarterly or tri-yearly inspections should be made, to see that the standard of equipment and care in operation were maintained. Much valuable information as to improved modes of construction and equipment could be disseminated by such an association, or even by your own association.

Surely the capital invested in generating plants would seem to warrant some general action looking to the standardizing and maintenance of them, and their insurance at a moderate cost.

.... Our first duty is absolute obedience to the law of nature in the construction of any machinery whereby we propose to convert a pound of coal into horse-power.—*E. N. Dickerson.*

FUEL OIL.

BY S. S. LEONARD.

(Abstract.)

During the past few months I have endeavored to obtain what information I could upon this subject from those who have been using oil, and especially from any electric light companies. The general experience does not seem to be very favorable, and I have been advised to have nothing to do with it; that the saving by its use over other fuels, if any, was more than counterbalanced by its injurious effect upon both boilers and furnaces; that the fire risk was greatly increased, and it would be found very difficult to place insurance upon our plant. One gentleman wrote me that he had just had a serious fire in his station, which could be clearly traced to the use of oil, and then kindly offered to sell me his outfit very cheap, should I desire to find out for myself, what they already knew, that oil was a failure. Others found that the use of oil was injuring their boilers by burning out the flues; some reported that it was almost impossible to keep their furnaces in repair, the cost of repairs amounting to more than was saved by the use of oil. As I read over these various experiences it carried me back to the time when we were going through the same trouble. Although we never injured our boilers, we did burn up a great many fire brick, and were obliged to rebuild our furnaces several times. Previous to experimenting with oil, I visited the East, and saw natural gas in use. I was impressed with its advantages, and when fuel oil was mentioned I thought I saw in it a substitute for natural gas. We were assured it was not necessary to alter our furnaces, but only to cover the grate bars with fire brick, put in the burner, turn on the oil, light it, and "let her go." I was delighted; but, alas, my expectations were not to be so easily realized. The oil was not all burned, and ran down into the ash pits, where it was set on fire; everything was dirty, and the odor was not agreeable. Notwithstanding all this, we still had some faith, and kept at it, and are now convinced that to make a success of burning oil for steam purposes it is as essential to have the proper settings or furnaces as it is to have a boiler to make steam.

We have been using oil for about eighteen months, and for the last six months exclusively under our seven boilers. The boilers are 14 x 60 inches, with forty-four four-inch flues. During the first part of the night these boilers are all in use, furnishing steam to four Reynolds Corliss condensing engines, from which we are using about 1,100 h.p. The steam pressure is easily maintained at any desired point, usually with us at 100 pounds. Our arrangement for the handling and storage of this oil I described in my former paper, and I only wish to add that so far it has worked admirably.

In speaking of the economy from the labor side, I made the statement that one man could attend to from seven to ten 150 h.p. boilers, which I am now positive of, as we have but one fireman at night and one during the day, while when using coal we had three men at night, and three or four during the day. It kept two men busy half a day wheeling out the ashes, and the other half was occupied in getting in the coal, and it was as much as one man could do to keep the flues clean. Now there are no ashes to cart out and no coal to cart in. Our flues are cleaned out once a week, and from the whole seven boilers there is not as much dirt as from one boiler with one night's run on coal. I am frequently asked if the burning of oil does not injure the boilers. A short time since the inspector of the Hartford Steam Boiler Insurance Co. made a very thorough inspection of our boilers. This same inspector had examined them a number of times when we were using coal, and was familiar with their condition previous to the introduction of oil; in reply to my question, "Did you discover anything wrong?" he replied that he thought they were in better condition than when we were using

coal. Our engineer has also examined them very carefully, and up to the present time has been unable to discover any evil effects from its use, so that from the length of time we have been using oil, and as no injury is apparent, I feel warranted in saying that the proper use of fuel oil will not injure a boiler. Improperly used, and by this I mean where the flame is allowed to strike the shell in any one spot continuously, it will soon damage a boiler, and the harder it strikes the sooner the damage; but this is true of any fire, whether it be coal, wood or gas; for, if the fire is blown against the shell as an oil fire is blown, it is only a question of time, and that not long, when the effect will be very apparent. By the proper adjustment of the burner this trouble can all be obviated, and the flame carried beneath the boiler, not up against it. I have already mentioned the expense of keeping in repair the settings or furnace as experienced by some who have used oil; this should not be, and is all wrong. We have furnaces that have been in use over a year, and they are in as good condition as when first built, and, as far as I can see, will last for a long time yet. Oil is very much easier on them than coal, is what our experience teaches. In reference to the burner, I would say that its requirements are few, but they are absolutely necessary to complete the success of using oil. It should be so made that it can be easily taken apart for cleaning when necessary; the oil should be all consumed that passes through it, whether the fire be a slow one or the burner pushed to its utmost capacity. It should not smoke, but produce a clear, bright fire. When our seven boilers are going full blast not a particle of smoke can be seen issuing from the stack. The fire should be as near the front of the boiler as possible, and not half way back, as I have seen it with some burners, for with the latter you are losing a large part of the capacity of your boiler, while the former heats the water the full length of the boiler at the same cost. "Do you find it cheaper than coal?" is a question very familiar to me. Yes, we do find it cheaper than coal in Minneapolis, but whether it would be cheaper than coal anywhere I have my doubts, as it would depend altogether upon the cost and quality of the coal used. The best quality of Illinois lump coal costs us from $3.25 to $3.50 per ton, while eastern coals are worth from $4.50 to $5.50 per ton; I refer to bituminous coals. The oil costs at present 2½ cents a gallon delivered in Minneapolis. In comparing tests made by us with oil and coal, we find that 2½ barrels or 104 gallons, costing (at 2½ cents per gallon) $2.60, will evaporate as much water as one ton of coal that costs us $3.15, being a saving of about 21 per cent. in favor of the oil. With one pound of coal we evaporated 5.38 pounds of water; one ton of coal would, therefore, evaporate 10,760 pounds of water. With oil 14.8 pounds of water were evaporated per pound of oil. Oil weighs about seven pounds to the gallon; one gallon of oil would therefore evaporate 103.6 pounds of water. With oil at 2½ cents per gallon, it would take 126 gallons to cost the same as one ton of coal, viz., $3.15; 126 gallons of oil would evaporate 13.053 pounds of water, while one ton of coal evaporates 10.760 pounds of water, being a difference of 2.293 pounds in favor of the oil, or a saving of 21 per cent. When I consented to write this paper I fully expected to have tests made as to what we were actually doing now by indicating our engines, weighing the water and oil used, etc., but circumstances have been such as to make that impossible. I have, however, calculated from the number of lamps burning and motors running the amount of power we are using at present, and by doing the same thing when using coal I find that the percentage of increase in power used is considerably larger than the increase in cost of fuel, being about 15 per cent. Although I am fully aware that this way of figuring is not absolutely correct, still my figures thus obtained are so near the others mentioned that I feel they are not far out of the way, and that we are actually saving in fuel alone at least 15 per cent., if not 20.

My attention has been called several times to the fact that the amount of water evaporated by us, viz., 5.38 pounds per pound of coal was very low; that is true, but the quality of coal used was very low as well. I have made a few figures showing what would be required of coal at various prices to equal the cost of oil. With oil at 2½ cents per gallon, a ton of coal costing $3.50 must evaporate 7.25 pounds of water per pound of coal to equal cost of oil; or coal costing $4 per ton must evaporate 8.28 pounds of water, and a coal costing $5 would have to evaporate 10.36 pounds of water to cost no more than oil. Our experience has demonstrated that it takes a very good coal to evaporate 10 pounds of water per pound of coal, and that quality would be exceedingly cheap at $5 per ton with us.

Those of us who are interested in electric light plants know only too well how they are considered by insurance companies. We have had some difficulty in placing insurance, notwithstanding that all of the insurance men who have inspected our system are agreed that they cannot see wherein the danger lies, or that the risk is any greater than it was with coal. When we first introduced fuel oil our insurance rate was raised from 1¾ to 2¾ per cent. At that time our arrangements for handling the oil were about as crude as the oil itself, and although we thought the rate exorbitant, we submitted, trusting that, should we finally adopt the oil for fuel, the insurance companies would restore the rate to about the old figures; but no, it made no difference whether the arrangement was good or bad, the rate remained the same. Under certain conditions you are permitted to use oil without extra charge, but those conditions are almost prohibitory, especially if real estate is at all valuable in the vicinity of the plant. As, for instance, if you keep the oil in tanks 200 feet from your building above ground, or 100 feet if underground, it can be used without extra cost, I believe. Some companies allow the tanks to be as near as 50 feet if underground. I do not believe the danger lies entirely in the situation of the storage tanks—in fact, I think that has very little to do with it. There is no doubt in my mind but that the tanks should be underground and so arranged that they can be got at, and should a fire occur in the building and it become necessary to shut off the supply of oil, it could be done at the tanks as well as in the building. Our tanks are about 25 feet from the building, underground. I do not mean to say that no restrictions should be put upon the use of fuel oil; there should be, by all means; but where properly put in there is as little danger as from any other fuel used, and by properly, I not only mean the storage tanks, but the entire outfit, burners, piping, furnaces and all. I am of the opinion that the insurance companies will soon discover that they are making a great mistake in condemning the use of oil on general principles.

LIQUID FUEL.

BY M. J. FRANCISCO.

(Abstract.)

At the present time we have no knowledge of any means of securing light without heat, and it only remains for us to employ the most economical fuel to produce the heat without useless waste. It has been asserted that the question of dividends in electric lighting lies between the shovel and the dynamo, and the fraternity have been taxed to their utmost to provide a plan for dispensing with the shovel entirely, and thus securing at least a part of the much coveted dividend. Petroleum, it is claimed, will furnish the substitute. One pound of coal contains 12,000 heat units, while one pound of petroleum furnishes 20,000. Engineers who are familiar with the practical workings of coal know that under the most favorable conditions not more than 10 pounds of water can be vaporized per pound

of coal, while petroleum shows a vaporization of 18 pounds of water for every pound of oil, estimating in both experiments the feed water at 212 degrees Fahrenheit. But when we consider the waste, amounting in some cases to 25 per cent., found in nearly all coal, such as sulphur, slate and earthy substances which are incombustible and retard instead of generating heat, the difference is far greater than shown by the above comparison. There is also in coal a large percentage of loss in transportation, and combustion in the heap, varying from 5 to 10 per cent. From these facts we can safely conclude that the heating capacity of oil is nearly twice that of coal as generally used.

On this basis the only question to be considered is the cost of power furnished by each at the dynamo. Three and one-half barrels, or 955 pounds of oil, equal 2,240 pounds of pure coal, therefore with oil at $1 per barrel and coal $3.50 per ton, or oil at $1.50 per barrel, and coal $5.25, the difference in cost would not be so marked, if there were no other factors to be considered. When, however, we consider the saving in stoking, removing cinders and ashes, cleaning flues, besides securing a steady heat, quickness in starting and shutting down, we have an argument in favor of oil that stockholders who care for dividends can appreciate. I have found, upon investigation, that oil can be delivered at my station for $1.05 per barrel, while soft coal costs $4.50 and hard $6 per ton. On this basis, allowing five pounds of coal per horse-power hour, 12 hours per day, 1,000 h. p. requiring 803 tons per month at $4.50 would cost $3,613.50. Two firemen to feed the same, $100; man cleaning flues, etc., $45; carting ashes and cinders, $100; making total cost for 30 days, $3,858.50 with coal. The same horse-power for same length of time, allowing three and one-half barrels for each ton of coal, would require 2,810 barrels of oil at $1.05. This would equal $2,950.50. Wages of one man in boiler room, $50, making total cost of 1,000 h. p. one month, with oil, $3,000.50, showing a saving of $858 per month, besides getting with oil a steady flow of steam, and consequent regularity of speed. If you are now burning coal, it will be necessary to equip your station with tanks, burners, cylinders, oil pumps, compressors, air receivers and additional apparatus, varying according to the number and size of boilers used.

During the past few months the following facts have been gleaned from an extensive correspondence on this subject with parties who are using liquid fuel. The Boston & Albany Railroad Co., after a careful test made in their shops say that the cost of fuel is about the same. Though they purchase their coal in large quantities at low rates, they prefer liquid fuel, because it is clean and requires no fireman, and gives a better supply of steam. Day, Cordage & Co., of Boston, claim that with Cumberland coal at $4.50 per ton, and liquid fuel at $1.15 per barrel, they save 15 cents per 100 h. p. per hour. The Fairbanks Scale Co., of Vermont, report that they find oil a great saving over coal, while the boilers are heated evenly the entire length, also that the insurance companies have not increased their rates. T. P. Brown, manager of the Toledo, Columbus & Southern Railway, reports a saving of 33 per cent. of the price of coal, by using liquid fuel, also that two barrels of oil equal one ton of soft coal, while manufacturers on his road find it only costs one-half as much as coal for their stationary boilers. The rolling mill works of Chicago, use it under a battery of 14 boilers, and say that three and six-tenths barrels of oil does the work of one ton of coal. The cost of oil is less than coal, but the great saving is in labor for stoking, wheeling ashes and unloading coal. Formerly, when using coal, 25 men were required to operate this battery of boilers for 24 hours; now, with liquid fuel, four men suffice. The efficiency of the boilers is increased and cost of repairs lessened, while oil flame is less severe upon the boilers.

Reference could be made to hundreds of persons who have had practical experience in burning oil, fully sustaining the facts given above, proving conclusively that liquid fuel is at least one-third cheaper than coal.

It is, however, necessary to consider many points before deciding to adopt oil, especially if your plant is in the centre of a large city with other property in close proximity. Managers of insurance companies are just cranky enough to believe that oil will burn, and unreasonable enough to object to your exposing and destroying property for which they have to pay. Therefore, they insist upon certain conditions before they consent to its use. Among other things, that you store your oil 50 or 100 feet away from your station. If this should happen to place your oil tank adjacent to your neighbor's property, you will have the officers of the insurance companies operating in a way that will drive grounds, short circuits and underground wires out of your minds for a month. If necessary precautions are taken, and the apparatus is properly and securely arranged, there is no more danger with liquid fuel than with coal. In fact, it may be made safer, and insurance companies will permit its use without an extra charge. Examine carefully, however, from an insurance standpoint, any apparatus offered you, before attempting to use it, or you may find that insurance is an expensive luxury, and operates fully as disastrously upon dividends as coal.

An iron tank will be required for storage of oil, which should be located underground 100 feet from your station. A pipe from this must pass underground to the car for unloading the oil. A second iron tank, holding enough oil for one day's use only, can be placed immediately outside the boiler house, with a safety pipe one and one-half inches in diameter extending 10 feet into the air, to permit the escape of gas. This tank must be connected with the large tank by an underground pipe for forcing the oil into the smaller one, with another pipe for an overflow to carry the oil back or away, in case the pump is neglected or left running.

The small tank must be lower than the burners or furnace, so that in case of accident the oil will flow back to it. In all pipes there must be stop-cocks that will cut off communication between the burners and tank. The supply pipe at the boilers should be arranged with a valve not over one-half inch in diameter, so that oil cannot, under any circumstances, be forced under the boilers faster than it is consumed by the burners; thus preventing an overflow from flooding the fire box. There must also be an escape pipe extending outside the building for cleaning the tubes. In no case must the oil be allowed to flow from the tank to the burners by gravity, but must be supplied either by vacuum process, steam or compressed air. For this there are several plans: One is to force steam across the opening of a vertical pipe from the tank, and thus draw the oil up to the mouth of the furnace. Another is to use compressed air for atomizing the oil, and passing it to the burners. Others still use a retort and generate a gas. Unless the apparatus used is expressly arranged for starting the fire, oil must not be turned on until the burners are heated, for if it is, flashes and explosions will follow. If a station is furnished according to these conditions, the insurance companies will insure it without extra charge. If not, they will demand from 50 cents to $2 extra for every $100 insured, according to any deficiency that may exist, while if the burners are fed by gravity, it is a prohibited risk.

Faraday has stated that the chemical action of a grain of water upon four grains of zinc can evolve electricity equal in quantity to that of a powerful thunderstorm. The Springfield (Ohio) Electric Light Co. found by a practical experiment, made last December, that a small quantity of petroleum under certain conditions could evolve a sufficient amount of flame to annihilate an electric light station without any thunderstorm. They placed a storage tank, holding 160 barrels, in the basement of the main building, and another in the boiler house, containing the supply for daily use. From the last tank the oil was carried to the fires by gravity. Having received a fresh supply of oil, they filled the large tank under the building,

then turned the oil into the small tank in the boiler room, and left the pump working, while the men were busy in another part of the station. It overflowed the tank, and the oil escaped into the furnace, with the usual results from gravity pressure, less oil, less building and less lights, with insurance managers running wild over the hazard of electric light buildings.

It behooves the members of this association to investigate this subject, and correct the errors of the past, if they do not wish all electric light plants placed upon the prohibited list. For why should the most powerful and magnificent system for the protection of mankind, known as insurance, and the youngest child of science, electric light, appear as antagonists?

ADVANTAGES OF OIL AS FUEL.

BY C. N. RANSOM.

(Abstract.)

THE use of oil as fuel for the purpose of producing steam is still, in a certain sense, an experiment, and yet it is no longer a question of whether it shall be used, but merely a question of the manner and method to be adopted. The advantages are so obvious that it is hard to find a man who does not believe that some method will be found by which a steady, smokeless, economical and easily controlled flame can be produced from oil by means of which boilers can be heated in a much more satisfactory way than is now done with coal.

A large part of this feeling is due to the belief that oil can soon be obtained at about half the present prices. The Standard Oil Co., in combination with the Producers' Association, is struggling to maintain the price, but in order to do so they are holding back a reserve stock of millions of barrels, which they can at any moment throw upon the market, and merely postponing the inevitable result, cheap oil. Meanwhile the California oil wells are extending, and aside from the Pennsylvania and Ohio fields, others of large extent are discovered in Wyoming and other sections of the country, as well as in Canada. The export trade for oil is becoming less and is likely to cease entirely, on account of the refineries erected by the Nobel Bros. in Baku, Russia. Quite recently Nobel Bros. have erected extensive refineries, and are understood to be constructing pipe lines, which must result in cutting off all our export trade in oil to Europe.

The heat-producing value of petroleum, compared with pure carbon, is as 28 to 15; and, compared with a fine quality of coal, as 28 to 14, or 2 to 1; and 1,000 pounds of petroleum are equal to a ton of coal. As petroleum weighs 6½ pounds to the gallon, 154 gallons are equal in heat-producing power to a ton of the present coal. In practice, however, the heat producing power of coal, as used under boilers, is very much less than the possible production stated. Referring to Professor Tower's work, we find that in actual careful tests of over 40 different articles of coal the highest evaporation reached was 10.7, and the other results varied from 6 upward, showing a loss from the estimated possible result of from 30 per cent. to 60 per cent. We have been unable to learn of a single instance in which a higher evaporation than 10.7 has been reached with coal, and have learned of only a few special tests in which an evaporation of over 9 has been reached. Such results have been reached only with exceptionally good boilers, with feed water heaters and the best of modern appliances to utilize all the heat, avoid radiation, etc., and with the best of coal and the most careful handling. In regular use, however, even in improved horizontal tubular boilers, with all improvements, the usual evaporation is from 7½ to 8½ pounds of water per pound of coal used, and in ordinary vertical tubular boilers the evaporation rarely exceeds 6 pounds of water to the pound of coal, and is oftener less than more. All these facts must be taken into account in considering the question of the possible value of petroleum as a fuel. Coal has been the universal fuel, and steam boilers are specially adapted and built for its use. Devices for producing perfect combustion of coal, and for utilizing the heat derived from it, have been patented by the thousand, and constant familiarity with its use in manifold ways has produced about as good a result with coal as we can well hope to reach, and this result summed up is that whereas one pound of coal can be made in laboratory practice to evaporate 14 pounds of water, yet in common use, in good horizontal boilers, the average evaporation is but 8, showing a loss of 43 per cent., and in common use, in upright tubular boilers, the average evaporation is only 6, showing a loss of 60 per cent.

Reverting to our former figures, it is evident that if 1 pound of oil is equal to 2 pounds of coal—under laboratory tests, where 1 pound of coal evaporates 15 pounds of water, and 154 gallons of oil equal 1 ton of coal—then when there is a loss of 43 per cent. on the heat-producing power of coal, as in horizontal tubular boilers, 88 gallons of oil (if there was no loss in using it) are equal to 1 ton of coal.

It is evident that if such results as these could be accomplished, and other objections overcome, oil would be in universal use.

Whether such results can be reached or not is difficult to predict. Inventions in the line of apparatus for burning oil to produce steam are comparatively recent. Nearly all of the inventions are in the line of atomizing or injector burners, and there are probably few, if any, horizontal tubular boilers in which oil is used as a fuel with any but an atomizer or injector. Burners of that description and of several forms have been in use for several years.

The Cincinnati Spring Co. wrote last June that they had probably used upward of 10,000 barrels of crude petroleum with atomizing burners, and preferred it to coal; and that they had tried all kinds of injector burners, but make one out of their own that suits them better. The Michigan Bolt and Nut Works, of Detroit, wrote on May 14th: "We tried the 'Askins,' the 'Chicago Edwards' and a simply constructed burner of our own, using gas pipe, and we liked ours as well as any." Studebaker Bros., manufacturers, of South Bend, Ind., wrote on May 14th: "We have not yet determined what make of burners is the best. We have had about as good results with one we made in our own shops as with any." Of this class of burners there are any variety in use, with more or less success. In my brick-making and certain classes of furnaces they seem to be regarded as being very satisfactory.

There have been, however, some serious objection to their use in boilers. In the first place, it is always necessary to make a fire in some other way first, in order to produce a sufficient pressure of steam to start the burners; and it seems generally the case that they will not work on less than a 30-pound pressure. One of the consequences is that if the steam happens to run down it can only be raised again by shutting off the oil and making a fire of coal and wood. They are, therefore, of no use, except where a long-continued high pressure and a constant fire are maintained. Another difficulty with that class of burners is that their practical use seems to be limited to horizontal tubular boilers, were the flame can be allowed to shoot through a long distance without coming in contact with the iron, the flame being thrown generally upon or against fire brick.

Messrs. Keasley & Mattison, the celebrated chemists of Ambler, Pa., say: "The furnace must be lined with fire brick, and satisfactory results can then only be obtained after the fire brick reaches a white heat. The fact seems to be that in the atomizing process the oil is sprayed in small globules, and if these globules strike a cool surface or one not excessively hot before they are entirely consumed, the result is imperfect combustion and a large amount of smoke." This peculiarity of injector burners seems to render their use impossible in locomotives or vertical tubular boilers. In fact, I have seen letters from at

least 70 different leading firms and well-known companies, located in almost every part of this country, stating in almost every instance that, while they knew of injector burners, etc., they never knew or heard of an apparatus for burning oil under boilers which did not require the use of steam or compressed air; nor did they know, nor had they heard, of any apparatus whatever for burning oil used successfully under vertical tubular boilers. I have also seen a letter from the manager of the fuel oil department of the Standard Oil Co., stating that he knew of only one burner which could be used under vertical tubular boilers. It is also a fact, I believe, that no burner has yet been brought into general use under house-heating furnaces. I believe it is now generally conceded that the use of atomizing or injector burners cannot be extended to embrace either vertical tubular boilers or boilers of the locomotive or portable type, or even horizontal tubulars below 50 h. p. In fact, the system of atomizing does not appear scientific. It seems upon its face a crude and clumsy way of producing combustion. I believe, however, that the members of this association recognize few impossibilities, and are convinced that a device can be made by which oil can be burned, and which can be easily and perhaps automatically controlled; and it would seem that such an apparatus would go a long way toward solving the problem of isolated lighting. For such a device we must, I think, turn to the system of converting the oil into gas first, and then burning it. Such a system is in accord with the principles of science. Of this class of devices the greater number have consisted of coils of pipe, maintained at a high heat, in which the oil is vaporized, and from which the vapor or gas issues in jets and is burned. These coils of pipe, however, I think, without exception, have proved failures, because of the coking or accumulation of sediment. Attempts have also been made to burn oil and water together, which have so far proved unsuccessful, chiefly because of the great difficulty in adjustment, and because they have been too complicated. Another defect has been that the vapor issuing from the tubes produced a smoky flame of comparatively small heating power. Still another difficulty has existed in the fact that if, by carelessness, the valves were opened too far, the oil would overflow.

Some time since my attention was called to an oil burner of the vaporizing type, which was submitted to several eminent scientists and to a number of practical men, and was approved by them. In that burner the oil was first turned into gas, and then gas, issuing in small jets, was mixed with air before combustion, upon the general principle of the Bunsen burner. The result produced was a steady, entirely smokeless flame. The cylinder was large and capable of producing more gas from the oil than could be discharged under light pressure through the jet holes, and the tank was elevated so as to give a gravity pressure of about four or five pounds to the square inch. The result was that the gas stood in the cylinder at an even pressure exactly equal to the gravity pressure maintaining the steadiness of the flame, and no oil would flow into the generator except as the pressure was lessened by the consumption of the gas, even when the fuel valve was opened wide.

Whether that particular device was or is the best or not, it seems to me that some device constructed upon that line must produce the best results obtainable, viz., the oil should be turned into gas and the gas burned after admixture with air, upon the same principle as ordinary gas is burned in stoves. Some of the advantages which a successful apparatus for burning oil would have are easily understood, and are: steady flame, perfect control, slight draft required, the power to increase or decrease the flame at will by the simple turning of a valve, the power to maintain steam at a steady pressure, the slight attention required, the power to extinguish the fire instantly without waste, the uniform heat, no reduction of fire or pressure when replenishing the fire, cleanliness, safety, economy in labor, no dust, cinders or ashes, less room required to store the fuel, and only one-third the weight.

With these advantages to be derived from the use of oil as fuel, it seems only reasonable to expect that within the near future some successful apparatus will be brought into general use for manufacturing and house-heating purposes.

CONDUITS; THEIR MATERIAL IN RELATION TO INSULATED CONDUCTORS.

BY ALEXANDER C. CHENOWETH.

(Abstract.)

Many miles of structures of various kinds with insulated conductors in them, are now to be seen in New York, Brooklyn, Philadelphia and other cities. While the conduits do not present any very important signs of decay, the insulation of the conductors has given evidence of decomposition in various stages, in some cases giving out entirely. Those covered with rubber compounds have given place to others, with some protected by a lead covering. Very little attention has been given to the subject of electro-chemistry; failure being attributed to various causes, remedies suggested by mere circumstance have been resorted to. That electro-dynamic forces have contributed to the trouble can hardly be denied. Creosoted wood ducts and iron tubes are the prevailing forms. Illuminating gas and moisture were found in most of them. Rubber insulation was rapidly destroyed, and lead-covered cables were corroded to such an extent in creosoted wood ducts that other cables covered with an alloy of tin and lead were substituted, and even with these it was found necessary to coat with paint. In the iron tubes corrosion was much slower.

After a careful examination of conduits and conductors, I am led to believe that decomposition of insulation and covering is due to electro-chemical action. The existence of a natural voltaic action in the earth, is without doubt true. But the establishment of the principle that a certain electrolytic intensity is necessary before decomposition can be effected, is of importance in considering the probable effect of the earth currents. For to produce an effect of decomposition or of combination a current must have a certain intensity before it can overcome the quiescent affinities opposed to it, otherwise it will be conducted, producing no permanent chemical effect.

Electro-chemical decomposition is produced by a force either superadded to, or giving direction to, the ordinary chemical affinity of the bodies present. In this view the effect is considered essentially dependent upon mutual chemical affinity of the particles of opposite kinds. Bodies dependent on weak affinities very rarely give way. Take for instance glasses, those formed by silica and an alkali. It is evident that in all cases in which decomposition does not occur it may depend upon the want of conduction; this being true, good conductors, such as iron, should never be selected for conduits.

I call your attention to a piece of cable taken from a creosoted wooden conduit in Brooklyn. The lead covering was eaten full of holes. It has been down over a year. Creosote was attributed as the cause of decomposition. Illuminating gas and moisture were present in the ducts. It was reported a rubber compound insulation was destroyed in the same duct. Examination was made of iron conduits with lead-covered cables in them, and decomposition was plainly seen in various stages, although the lead covering was not so rapidly decomposed as it was in a creosoted wood duct. Moisture and illuminating gas were present. The deposit on surface of lead proved to be carbonate of lead.

In pursuing this examination I found a peculiar case deserving consideration, I found exposed to view in a man-hole a cable that was covered with an alloy of tin and

lead. This cable had been down about four months; it passed through the man-hole into the duct; the part exposed to view was about seven feet; the duct was constructed of iron and cement. On one side considerable decomposition appeared, being very active for about two feet of the exposed part, which rested on the bottom of the man-hole. A large iron pipe for water traversed the man-hole parallel to the cable. The crystals of decomposed lead extended toward the iron pipe, being quite profuse, adhering to the brick and side of man-hole. On examination the white crystals proved to be carbonate of lead. Moisture was present, but no illuminating gas. I placed a piece of lead on the cable at this point. After two months I removed it and found the same covered with crystals of carbonate of lead, showing signs of electrolytic action between the lead-covered cables and iron pipe, moisture acting as the exciting liquid.

I found in Brooklyn a cable that was conducted into a building some distance from a creosoted wood duct; this cable was also decomposing in spots, while no odor of creosote or illuminating gas could be detected. The moisture may be the exciting agent, accelerated by creosote and illuminating gas. This action may be explained by the reaction of the constituents of each portion of decomposable matter, affected as they are by the supervention of the electrical currents; portions of the proximate or ultimate elements proceed in the direction of the current as far as they find matter of a contrary kind capable of effecting their transfer, and being equally affected by them; and when they cease to find such matter they are evolved in a free state upon the surface of metals or air bounding the extent of decomposable matter in the direction of the current. Hydraulic engineers frequently find an electrolytic action set up in stopcock valves underground when they are made of two kinds of metals. Examination has shown that water impregnated with iron or saline matter has produced this action. I was informed by a very eminent engineer, who is now chief of the Croton aqueduct in New York city, that metals of different kinds underground invariably present marked evidences of decomposition when in contact. Faraday has shown that these electrolytic actions do not depend on contact alone.

In order to avoid any electro-chemical action, iron tubes, creosoted wood ducts, or any material that can become the means of establishing this action should be discarded.

A triple silicate of lime, magnesia and alumina, artificial stone, form a substance more neutral than any other. The selection of this material for underground structures in form of concrete was probably the result of long experience rather than the knowledge of its physical relations, as presented by electro-chemistry.

Attempts to counteract the electro-chemical action on a lead covered cable by placing another substance in juxtaposition has not proved a preventive; it may delay it; this is also true of alloying tin with lead. Metals may combine when melted together, but they do not remain combined after the solidification of the mass. I present here an example. I refer to a piece of brass tube that was used for pneumatic transmission by the Western Union company in New York, being buried in a wooden box in one of the streets. After it had been down some time it was so eaten full of holes that it required renewing. Upon examination you will find the zinc is eaten out, while the copper remains; the action was on the outside, while inside the brass remained perfect; air traversed the inside continually, while moisture and other agents produced an electro-chemical action, thus showing the peculiar effect of the earth currents in decomposing the zinc in this alloy, then removing it entirely. Moisture and gases must be removed by ventilation. In order to accomplish this the diameter of the conduits should be not less than four inches, and some relative proportion be established between the diameter of the cable and diameter of the duct, otherwise the power required to force air through would be beyond an economic limit.

The subject of ventilation for electrical conduits not only becomes important in order to protect the conductors in them, but in order to protect life and property. Thursday, December 20, 1888, an Edison man-hole exploded in Maiden Lane, New York city. January 19, one month later, an explosion took place in Nassau street. In November, an Edison man-hole exploded in Boston. These explosions have been attributed to accumulation of gas.

MUNICIPAL LIGHTING.

BY FRED. H. WHIPPLE.

(Abstract.)

"MUNICIPAL LIGHTING," as generally considered, means the municipal ownership of the plant. I think this definition is erroneous, for the reason that the greater portion of the income of two-thirds of the electric light companies of the country is derived from their public street lighting contracts. Of the total number of arc lights manufactured by private companies who are parties to a city contract, 68 per cent. are public lights, and are paid for by the municipalities. On the other hand, of the total number of arc lights upon the streets of the land, but one-third of one per cent. are owned and operated by municipalities. Therefore the subject is not confined entirely to the question of ownership. The issue, to my mind, is based as much upon the rental value of an arc lamp.

What is the rental value of an arc lamp? Statistics regarding the price paid by various cities are not lacking; but comparisons are worse than useless, for they seemingly go upon the principle that a light is a light, no matter what it lights, what it costs to produce it, whether it has good illuminating capacity, or whether the system be an inferior or superior one. The prices for light vary materially in different places, but I have been unable to see that they vary in accordance with any fixed relation to any other factors. It would be impossible to prove, on a general hypothesis, that 50 cents, or any other sum, is in any place the exact value of an arc light; but in this, as in all other cases, some price must be fixed.

In staple articles the law of supply and demand regulate prices; but as electric light companies, in their relations to city councils, act under influences individual in themselves, the case is different. The price of light for commercial purposes is to some extent regulated by the fact that moderate prices materially increase the consumption, but in municipal lighting, the city, if it accepts the terms offered, generally pays the contracted price. It is, therefore, in many if not in most cases, a matter of comparative shrewdness on either side as to the price paid, and the service rendered.

There are to-day in the United States 316 cities and towns whose streets are wholly or in part illuminated by electric lights furnished under a public contract. The highest price paid for an arc light of nominal 2,000 candle power, burning all night, is $360. The lowest is $40. Between these two extremes there are 186 prices. Upon the moonlight schedule the maximum figure is $165; the minimum $50.

What makes these wide differences in price? Granted that in many places local conditions, excessive competition or the absence of all competition have weight, what reason shall we give for the varying figures exhibited in a wide field of localities where the conditions are almost identical?

The average cost of all-night public lighting in the United States to-day is $121 per light; for schedule lighting, $110. In 1885 the cost was, on an average, $167 per light for all-night lighting, and $135 for schedule lighting. In 1886 it was $160 and $125. In 1887 it was $130 and $117. In 1888 it was $129 and $114. Thus we find that

the price of public lighting has been steadily decreasing for several years, and to a large extent within the past few months. Contracts that have been renewed since the last meeting of this association in August show a net reduction upon all-night lighting of 23 per cent., and upon schedule lighting of 19 per cent. The general run has been from 15 to 33 per cent., but there are several cases reported where the reduction has exceeded 50 per cent. An increased contract price is rare.

These statistics do not furnish any guide as to the rental value of an arc lamp. The price paid by one city is often twice as much as that paid in a neighboring city. It is obviously worth more to produce a light in one place than in another, but is it worth twice as much? It will no doubt be said that different degrees of illuminating power enter into the problem, but in my computations I have considered none but nominal 2,000 candle power lights. Sometimes the area lighted is pushed forward in explanation, but this has no connection that I can see with the cost of the light itself.

There is really no fixed basis upon which to charge for public lighting, nor any general data by which a fair rate may be arrived at. I am, therefore, of the opinion that coincident with the discussion of ownership should come that relating to the value of the light, for this is really the primal cause for so much agitation of municipal control.

When it comes to the question of ownership there are three parties in interest: the parent companies who manufacture the material to be used, the local companies that have invested their capital in a business they have the right to make lucrative, and the public, represented by municipal councils. Accordingly, we find three separate views taken of the question, and are forced to believe that all three are right from their standpoint.

Of the three factors the local companies are the only ones presenting a solid front. They are united in the opinion that municipalities ought not to do their own lighting. In view of the constant decrease in the price of electric lighting, and the transitory periods of electrical machinery, the local companies are correct in their claim to be able to generate electricity as cheaply as a municipality. Many of the circumstances by reason of which the sentiment favorable to municipal ownership became prominent do not have force to-day. The improved methods and cheapening processes private companies are able to take advantage of where municipalities would not. Compound and condensing engines have made it possible to reduce the cost of power; light is produced from a less expenditure of energy; carbons have fallen from $50 and $60 to $8 and $10; it is no longer necessary to locate a station in the central, and therefore most expensive portion of a city, and more attention is given to water power. All those are contributary to the claim of the private companies that municipalities should not enter into an investment the extent of which they are ignorant of in the face of a declining market.

With the parent companies the effects of municipal ownership are just beginning to be appreciated. There is no doubt but these organizations will at no distant day be brought squarely to face the alternative of refusing to sell material to municipalities altogether, or of going out of business. It has been their custom, while acknowledging an unwritten obligation to protect their local companies, to consider that they are not bound to refuse a sale. They are not prepared to say that it is inadvisable for a city to operate its own plant so long as the city already has the other company's system installed. When it comes to a city which has a private plant of this or that particular system, then this or that particular parent company is decidedly opposed to the city embarking in the business.

No parent company is large enough or financially strong enough to organize and operate the local companies necessary for the times. Therefore it is local capital that is the mainstay of the parent companies. Capital is always nervous, and we can readily see that with the continued growth of a sentiment favorable to cities doing their own lighting, capital will not run any risks. It will not invest in a city or town where a community interest stares it in the face.

I do not believe there is a parent company in the country that has made money by selling plants to municipalities; I know some who have lost money, and I wonder that as a whole they are not ready to commit themselves unqualifiedly and negatively upon the subject of municipal ownership. The time is near when they will be forced to go upon record in this matter, but to-day they are vacillating and uncertain.

The theory of some political economists is that the monopolies of service should be owned by the municipality, and all belong to the community. In European countries this idea is carried to a much farther extent than in our own. In America this doctrine has made less progress, and considering the character of our political methods that is well. Municipal service can be, and ought to be, quite as free from corruption as when in private hands. But in few instances do we find it so. I believe I can truthfully say that the experience of city governments in electric lighting has not been in all respects satisfactory. Starting out a year ago as the investigator for a large municipality, I have closely studied the working of almost every city plant, and with but one or two exceptions I would not commend their operation. The officials of the smaller towns where municipal plants have been installed, with an amount of crude ignorance of the subject that is truly appalling, do not hesitate to assert that they and the people are well satisfied with the experiment; but in the majority of cases these officials are in office through the machinations of rings.

On one occasion, where I was called upon to estimate the cost of all-night service for a large city, upon its merits, my figures were $92 per year, with interest and depreciation, and that I think is not very far from the cost of an arc lamp in our average communities. A strong claim is made that municipal stations have reduced the cost of public lighting in their localities over the contract system.

I have previously stated that the average present price of public lighting in the United States is $121 per arc lamp per year, burning all night, and $110 per lamp burning on schedule. The average cost to municipalities which are furnishing their own light is $76 for an all-night light, and $44 for what they term a schedule light. This schedule is deceptive, and does not provide for as many hours' lighting as the usual contract does. Therefore, the latter suffers by comparison. It is often the case, also, that the light is furnished in connection with some other department which bears a portion of the interest and depreciation account. Free water power and sometimes so-called free attendance also enter into these figures and distort them.

The only argument worthy of consideration in favor of municipalities doing their own lighting is that of cheapness, and emphasizes what I have said, in a previous part of this paper, that an important question involved is the rental value of an arc lamp. Municipalities have not yet succeeded in reducing the price of light abnormally below the average. I do not consider the fact of any weight that a city, by reason of its not being compelled to pay taxes, and because it has no profit to make can manufacture light cheaper than a private company, for I expect that what it saves in this way will be counterbalanced by losses caused by the influences of its management.

Here arises the question of a personal financial responsibility. We have become accustomed to consider that all public business, being in a sense everybody's, is really nobody's, and too often it is the case that a mere perfunctory public duty is performed for the sole sake of the salary attached to the office. Any business enterprise, to be con-

ducted successfully ought to be carried on by men who are financially interested in it, and who feel in their own pockets the cost of every expenditure. A city government cannot possibly take that view of it, even though its departments were paved with good intentions.

The price of public lighting has outstripped all other questions in the financial management of our cities. It has become, if not the chief source of expense, the greatest bone of contention, and the electric light companies that will observe the handwriting on the wall and meet the subject half way will do much to dissipate the sentiment antagonistic to its interests.

MUNICIPAL OWNERSHIP OF COMMERCIAL MONOPOLIES.

BY A. R. FOOTE.

(Abstract).

The true name of this subject, designating accurately the economic principle which it advocates, is Municipal Slavery—a scheme to enslave capital and pauperize the people. The economic principle advocated is not in accord with natural economic law; therefore, it is an obstruction to the progress of civilization.

Those here assembled know that all progress is due, and must ever be due, to the discoveries of science made available for the uses of man. The nearer we arrive to an understanding of natural law, the nearer we apprehend the truth. Actions guided by truth are the guarantors of benefactions. You who have experimented, with great patience and at great cost, to discover the natural laws governing the generation and control of electric energy, know how impotent all your devices are to compel that energy to serve you, if they fail to comply with the conditions of those laws. The same fact is true in economic science. If economic policies do not comply with natural economic laws, the effort is impotent to secure the best economic results.

Public ownership of commercial monopolies is advocated upon the supposition that, if worked without a profit, the economic result will be a benefit to the people. Work without profit is slavery. Slavery is not an economic benefit.

That capital is entitled to a profit for its use and risk is the foundation law of all economic science. There is not a recorded instance in the history of finance where an interference with the operation of this law has secured a permanent benefit for the people. All evidence shows that, where this law is allowed to operate with the greatest certainty, there capital is most abundant, works on the smallest margin, and produces the most healthful progress.

Capital is the conserved energy of individual action ; it never loses its individual character.

When the attempt was made to christianize communities by government authority, they remained heathen. When communities attempt to become rich by operating commercial monopolies without a profit, they will be made paupers.

A man's capital is his power to produce. Surplus is the product of energy in excess of the wants of life. Capital is the conserved energy of surplus. Surplus is an individual creation, and belongs by natural right to its creator. To abrogate the law of increase for use and risk is to destroy the only economic inducement men have to create a surplus. Deny men the ownership of their surplus, and they are forever slaves. Deny men an increase for the use and risk of their surplus, and the forces of progress will be paralyzed.

The application of these generalizations to the question before us is easy.

First. There is no municipal surplus, unless it is taken from the surplus of individuals by taxation. This makes the individual poorer.

Second. Working public monopolies for a profit is securing income by indirect taxation. Indirect taxation is a tax on consumption.

Third. When public monopolies are not worked for a profit, their products are sold at a reduced price. This compels all private capital to abandon the business undertaken by public monopoly. By this process all the forces of progress for that industry are paralyzed.

Fourth. Every industry grows as long as it produces, or gives promise of producing, a profit for the use and risk of the surplus invested in it. When, for any reason, the hope of profit fails, the industry dies. Expectation of profit is the life of industry. Its growth is the ratio to the per cent. of profit promised, plus the certainity of securing it. In the beginning, surplus created in some older industry is transferred to a new undertaking to give it life. If the new undertaking fails to create a profit, it loses its power to draw life from other industries and dies. It has failed to demonstrate its right to exist. For this reason, that man who so orders the conditions under which an industry must be worked as to deprive it of the power to create a profit is its murderer.

I know of no industry which has been developed to the best of which it is capable under public ownership. This subject may be illustrated by reviewing the development of the gas lighting industry.. Sixty-eight years ago, the first plant in the United States was installed in the city of Baltimore. To-day there are about 1,000 plants in operation, which have cost about $500,000,000. If this industry had been worked under conditions depriving it of the power to create a profit, could this enormous capital have been collected by taxation? If not, by what means would the cities of this country have obtained the benefits of gas lighting? This is not all. The power to create a profit, and the right to own the profit created, has proven a powerful stimulant to invention and improvement. By these processes, service has been improved and cost reduced, until the present price is but a fraction of the original charge. In 1878, the average price of gas in 290 cities was $3.15. In 1887, the average price for the same cities was $2, a decrease of 33 per cent. in nine years. The process is still going on. The decrease in 1888 was in a greater ratio than the average for the preceding nine years.

Four gas plants are owned by municipalities—Philadelphia, Pa.; Richmond, Va.; Wheeling, W. Va., and Danville, Va. Not one of the inventions or improvements that have benefited service or cheapened cost have emanated from either of these plants. Neither of the older works are in line with the improvements of to-day. Richmond is now engaged in improving its plant. When the work is finished, as ordered, it will be in line with the improvements of ten years ago. One special point avoided in making changes is the reduction of the number of employés. Is there any political significance in this? Philadelphia has just contracted with private capital to furnish 3,000,000 feet of gas per day to the city gas works. Why? Because the city cannot make it for itself, as its works are not supplied with the necessary improvements.

Here is a comparison of the price of gas in six cities :—

	1873.	1888.	Per cent. of decrease.
New York	$2.75	$1.25	54½
Philadelphia	2.30	1.50	35
Baltimore	2.75	1.00	63½
Richmond	3.00	1.50	50
Cincinnati	2.25	1.15	49
Cleveland	2.50	1.00	60

But why give data and make comparisons that have no scientific value, because all the factors influencing the result are not considered? If public ownership is not founded on correct economic principles, then the result of such ownership cannot produce the best economic results.

Let us now consider the effect of public ownership on our own industry. It is acknowledged that no city has yet undertaken to supply its citizens with a complete electric

service. If the industry is to be developed by public ownership, why do not these cities commence in line with the progress that has been made? If they have not the enterprise, can there be a reasonable hope that they will ever catch up, keep up, or contribute to the forward momentum? To-day, private capital is ready to install electric central stations having proper apparatus and sufficient capacity to perform the entire electric service of a city.

This service now includes:—Arc and incandescent lamps for street lighting; arc and incandescent lamps for commercial lighting; incandescent lamps by meter measurement for domestic lighting; stationary motor service for all mechanical uses; motor power for operating street cars.

One of the largest companies manufacturing electrical apparatus has installed electric central stations in about 160 cities. The combined capacity of these stations would fall far short of performing the entire electric service for the city of Chicago, if the service in that city was developed to the best of which it is capable. Can anyone calculate the difference in cost of installation, operation and administration between one station, combining the capacity of the whole, and that of the 160 stations located in as many different cities? To-day, electricity is at its highest cost, and gas at its lowest cost. Gas has fifty years the start.

To supply a complete electric service to the cities of this country, in a manner now known to be practical and best, will require the investment of over $1,000,000,000. Do the manufacturers of electric apparatus expect this vast sum to be raised by successive tax levies? If not, then they must secure its accumulation through private ownership, operating electric central stations for a profit. There can be no hope that the electric industry can reach the highest degree of prosperity of which it is capable, if it is sold into slavery in its youth.

Fortunately for us, our industry is not the only one needing defense against the promulgation of communistic theories. Those who advocate such theories are consistent enough to push them far toward their logical conclusion. It is well that they do so, for it is the most helpful service they can render those who would resist the encroachments of their economic policy.

Doctor Richard T. Ely, associate professor of political economy in Johns Hopkins University, may be recognized as chief in the school of communistic philosophy. By reading his books it is easy to see how, as he familiarized himself with the idea of public ownership, the list of so-called "natural monopolies" expanded, until by it he furnishes a logical reason why all industries should be so owned and operated, if any one of them should. A mere mention of the monopolies he recommends cities to buy will give a good idea of the progress he has made in communism. They are as follows:—Gas supply, street car service, highways and streets, electric lighting, all railways, canals, bridges, lighthouses, ferries, docks, harbors, natural navigations, postal service, telegraphs, telephones, abattoirs or slaughter-houses, markets, union depots, express business. This list illogically associates non-commercial with commercial undertakings. In it are embraced a large percentage of the industries of the country. If it is so desirable for the public to own so many, why specify? Why not own all industries? It would be interesting to know what additions would be made to public investment, public income, public patronage, and to the number of public employés, if the recommendations of this economist were acted upon, and this entire list of undertakings were transferred to public ownership. Could the party then in power ever be voted out?

This list is serviceable in another way. It shows the interests that should unite with us in combating communism.

In his address before the Boston Merchants' Association, at its annual banquet, January 8, 1889, Professor Ely said:—"I say, then, that cities should pursue a policy looking to the ultimate ownership and management of all local monopolies. * * * This is most intimately connected with local taxation. One of two methods may be pursued.

"*First.* These monopolies may be worked for a profit, and by profit taxes may be reduced; or,

"*Second* Charges may be reduced, and increased general prosperity will furnish a more plentiful source of taxes, and thus allow a reduction of the rate."

Profit on the products of public monopolies is taxation on consumption. Taxation on consumption is indirect taxation.

Since Professor Ely recommends that gas lighting, electric lighting, street car service, and numerous other industries be owned by the public, and then operated for a profit to reduce taxation, it will be well to learn his views on indirect taxation. Here they are:—

"Indirect taxes violate the principles of equity, * * * we import salt and tax it 50 per cent. of its value. Does the rich man consume more salt than the poor man? * * * We have in a tax like this what is called a regressive tax, a tax which increases as income decreases—*the worst kind of a tax, and the most unjust.* * * * Indirect taxation does not discriminate between the last dollar of the poor widow and the dollar which is only one in an income of a million. It raises prices, reduces the value of income, and forces some who are already near the awful line of pauperism to cross it, and thus puts to death higher aspirations in a class of citizens, and lowers the level of civilization. * * * Indirect taxes are imposed upon people without creating so much discontent as direct taxes, and without occasioning so close a scrutiny of the methods in which the proceeds of taxation are expended, because the mass of men do not realize that they pay taxes every time they purchase dry goods or groceries. Indirect taxes are an underhanded kind of taxation. It is not, then, surprising that they are, in the minds of many, identified with despotism and aristocracy, while there is a growing opposition to them on the part of enlightened democracy."[1]

Is it not surprising, that an economist who sees the character of indirect taxation so clearly should recommend those who are so oppressed to extend the list of oppressors from dry goods and groceries to gas lighting, electric lighting, car fares and a long list of other things? Are the rich so poor that it is necessary that one penny out of every car fare paid by the poor should go to help reduce their taxes, or are they mean enough to want it done? Suppose that all these industries were owned by the public, and the profits on them were sufficient to pay *all* the taxes, would not the payment of the tax be in inverse ratio to the income of those who pay it? Can any form of tax be more inequitable, more unjust? The short of the first proposal is, then to tax the poor and relieve the rich.

That which has been said about the slavery of capital is a sufficient answer to the second proposal.

He who assumes to be a scientist and a teacher should be accurate. Professor Ely is reported to have said, without explanation, in his Boston address: "Gas can be made and sold at a profit for 37 cents. I say it can be done, because it is done in the city of Philadelphia; parties supplying the city with gas at that figure." What do you understand by that? Does it not convey to you the idea that the consumers of gas in Philadelphia are being supplied at 37 cents? Well, the truth is, that the gas works are owned by the city. On account of a lack of the latest improvements, the city has contracted with *private capital* to supply 3,000,000 feet of gas per day. This is a carbonated water gas of high candle power, and is mixed with the city coal gas to increase the output and improve the quality of the gas manufactured by the city works. The

1. See Taxation in American States and Cities.

consumer of gas in Philadelphia pays $1.50 for his gas as before. This is held as a sample of the benefits of public ownership. This from a teacher of economic science!

Professor Ely presses his point still further, by saying: "It was the best citizens of Philadelphia who insisted that the gas works should remain city property when the gas trust expired." What scientific or economic value has a reason like that? It is the argument of a politician, from the fact that he is teaching that a tax of one penny in every street car fare "would relieve to that extent the business men of cities from their load of taxation," it is fair to presume that by "best citizens," he means the respectable wealthy people. *They know* that the $3,000,000 which they found in their budget of 1887, as receipts from gas (Taxation in American States and Cities, page 271a), came by indirect taxation from the people who consumed most gas—the majority—who are poor. This is the reason why THEY insisted that the gas works should remain city property.

One of our "best citizens" is seeking to ease the burden of taxation for the rich, by collecting pennies from the poor, under cover of charges for gas lighting, electric lighting, street car fares and other products of industry. He advocates an economic theory which must result in the slavery of capital and the pauperization of the people.

ABSTRACTS AND EXTRACTS.

A DESIGN FOR A STANDARD OF ELECTRICAL RESISTANCE.[1]

BY J. A. FLEMING, M. A., D. SC.

(Professor of Electrical Technology in University College, London.)

In designing a standard of electrical resistance the two points to which attention is directed are the choice of the material in which the standard is embodied, and the form or disposition of the instrument.

Experience is yet far from complete as to the entire permanence of wires of alloys over prolonged periods of time when employed as standards of electrical resistance; but having regard to the inconveniences which attend the use of mercury in standards intended to be conveyed about, evidence, as far as we have it, points to the tolerable permanence of the platinum silver alloy (66 p. c. of silver + 32 p. c. of platinum) when drawn into wire, for use as the material substance of which the actual standard is made.

A definite length and gauge of standard wire has then to be so arranged that, whilst kept at a constant temperature, currents can be passed through it and the resistance between certain points ascertained.

The form which has hitherto been chiefly manufactured, and which is in most general use, is the form of standard which was designed by the committee of the British Association on the original introduction of the B. A. unit. In this form of standard the actual coil is wound on a bobbin, consisting of a tube of thin brass having ebonite cheeks. Attached to these cheeks are the two long bent copper rods which serve as the electrodes, held in position by a distance piece of ebonite. In order that the coil may be immersed in a medium of known temperature it is further enclosed in a thin shell of brass consisting of a double tube, and the whole shell filled up with paraffine wax or ozokerit. Some makers then place a thin lid of ebonite on the top of the shell.

Experience gained by a rather extensive use of standards of resistance of this form has indicated to the writer that this design can be, with some advantage, modified. The disadvantages of the present B. A. form of standard are as follows:—When in use the standards must be placed in water of a known temperature or in melting snow or ice. After a sufficiently prolonged time the temperature of this water can be taken, and the temperature of the water will be the temperature of the wire of the standard, assuming that equilibrium of temperature has been attained. If a current is now passed through the coil in order to take a measurement of its electrical resistance, the temperature of the wire is raised, and its resistance is altered.

Other things being equal, the best design of coil is that in which this electrically developed heat is got rid of by diffusion as quickly as possible. The embedding of a coil in a large mass of badly-conducting material like paraffine or ozokerit is, from this point of view, a great disadvantage.

Sufficient electrical insulation has to be provided; but this should be achieved without the use of more enveloping insulation than necessary.

The two chief objections to the B. A. form of standard are, however, these:—

1. It cannot be placed in water with the shell wholly under water or under ice without short-circuiting the electrodes, and, when used as intended, whilst the narrow or bottom portion of the coil is in the water, the upper and more massive portion is in the air, and therefore may be at a different temperature to the bottom portion. Hence arises a doubt as to the actual temperature of the coil of wire. It has to be borne in mind that the limitation of accuracy in such comparisons of standards of resistance is determined by the difficulty of ascertaining temperature, and not in the mere measurement of resistance. Uncertainty as to the actual temperature of the wire to the extent of one or two-tenths of a degree Centigrade renders nugatory elaborate arrangements for very accurate measurement of resistance.

2. The standards, as at present constructed, are liable to another defect. If the standard is being used in melting ice or snow, and therefore cooled to 0° Cent., deposition of dew will take place upon the upper surface, whether it is the ebonite lid or paraffine-wax surface, through which the

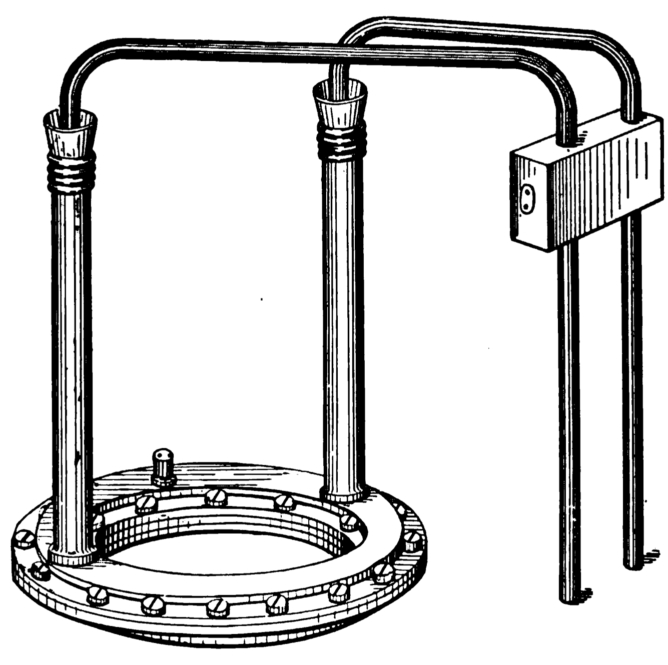

Fig. 1.

copper rod electrodes protrude. The copper rods are originally lacquered or varnished, but when the lacquer wears off, any film of moisture so deposited will short-circuit the electrodes and reduce the observed resistance. In comparing standards in melting ice, either then the whole shell must be as far as possible placed under the melting ice, in which case stirring the liquid may splash water on to the surface of the paraffine, or else the shell has to be only partly immersed, in which case ambiguity exists as to the actual temperature of the coil of wire.

1. Abstract of Paper read before the Physical Society, on November 10, 1888.

These and some other difficulties, such as that of keeping a rather deep vessel of melting ice at a constant temperature, have impressed on the writer the necessity for modifying the form of the standard; and one form which has proved itself to be very satisfactory in use is as follows:—The case or shell which contains the coil is in the form of a ring (see figure 1). This ring consists of a pair of square sectioned circular troughs provided with flanges which can be screwed together so as to form a square sectioned, hollow, circular ring.

From this ring proceed upwards two brass tubes about five or six inches in length. Down these brass tubes pass the copper electrodes or rods, and these rods are insulated from the tubes at the top and bottom by ebonite insulators. The insulator at the bottom of the tube, where it enters the ring, is a simple collar, that at the top has the form of a funnel corrugated on its outer surface. The use of this funnel will be referred to presently. The actual resistance coil is a length of platinum silver wire three-fold silk covered. The silk-covered wire is first baked above 100° C. to dry it completely, and then immersed in melted ozokerit or paraffine.

The so insulated wire is cut about the proper length and laid double or folded once upon itself and then rolled up on a wooden mandrel so as to form a circular coil of diameter suitable to drop into the hollow of the brass ring. The wire being wound double, its coefficient of self-induction is rendered very small. This coil of wire is then wrapped over with white silk and again dipped in melted ozokerit. The ends of the wire are next soldered into nicks in the ends of the copper rods, they having been previously pushed a little way through the brass tubes for the purpose, and afterwards drawn back into proper positions. The coil is then packed into the circular groove, and, after adjusting the resistance to the proper value, the bottom half of the ring is placed over it. A thin washer of india-rubber is inserted between the flanges, and the whole screwed tightly together. The resistance coil is thus enclosed in a thin ring of metal, and can be placed wholly below the surface of water or ice. In order to test the tightness of the joints, a little test pipe is provided on the upper surface of the ring. By placing the ring coil below water and blowing into the test pipe, the good fitting of the joints can be assured. The aperture of this test pipe is afterwards closed by solder or a screw (see figure 2).

Apart from the insulation of the coil itself it will be apparent that the insulation is limited by the amount of insulation resistance secured at the ebonite insulators at the top end of the brass tubes. Any leakage from the copper rod over these insulators to the brass tube destroys to that extent the insulation of the coil. The object of making these external insulators funnel shaped is to prevent surface creeping, due to condensation of moisture on them, by placing paraffine oil or insulating liquid in the funnel-shaped cavity. When this is done, even if dew should collect on the outer surface of the funnels the inner surface is kept dry by the paraffine oil placed in them, the action being the same as that in the well-known Johnson and Phillips fluid insulator.

The ring coils when in use are placed in rather shallow zinc troughs, which can be filled with water, and which are closed with a wooden lid. When so placed the whole of the actual coil or resistance part is down beneath the liquid at one level, where the temperature can be accurately ascertained. The insulators and point of emergence of the electrodes are away up above the level of the water, and well protected from any action which might permit of leakage over them. The large metallic mass of the ring assists in bringing the resistance coil quickly back to the temperature of the surrounding water, and the coil therefore "tests quickly." In all other respects these standards of resistance are as compact and portable, and not more expensive to construct than the old form of B. A. standard, whilst obviating the difficulties which present themselves in the use of the old form in very accurate comparisons of resistance.

It is quite possible to have two or more coils of wire inside the same ring, each coil having its separate pair of electrodes. A useful coil of this form can be made up containing 1, 10, and 100 ohms, so that comparisons can be quickly made at the same temperature with these three multiples of the same unit of resistance.

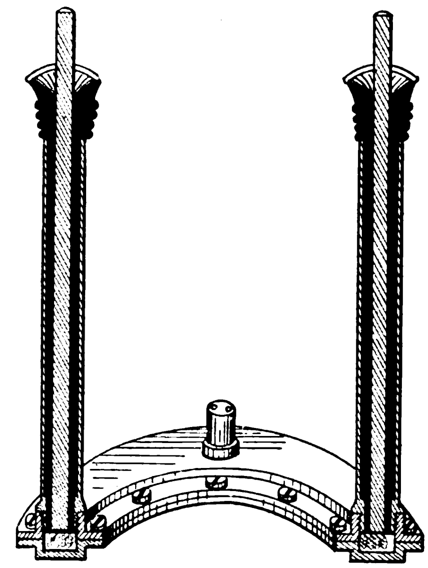

Fig. 2.

The adjustment of the coils to a certain value presents no great difficulties. The wire is in the first instance cut a little longer than required, and its resistance nearly adjusted; when the two ends of the coil have been soldered to the lower ends of the copper rods, the resistance is again taken from the ends of the electrodes. This resistance should be a little greater than the final value required. The middle point of the wire or extreme loop is now stripped of its silk and the loop twisted up with the pliers, the resistance being carefully taken at intervals. When just a very little in excess of the value required the twisted coil is touched with solder, and having been bound over with insulating material the coil is completed. In the construction of standards it is obvious that it is not so important that the resistance should have an exact integer value at any temperature as that its value at some temperature and its coefficient of variation of temperature should be exactly known.

CORRESPONDENCE.

NEW YORK AND VICINITY.

New Roads Proposed.—Mr. Edison's Birthday.—Mr. Edison's Exhibit at Paris.—The "Times" View of the Board of Electrical Control.—The Fulton Street Electric Railway.—A Cable Bill before the Legislature.—Meeting of the Electrical Section of American Institute at the "C. & C." Factory.—A New Motor.—A Yale Professor Objects to Overhead Wires.—Explosion in the Subway.

A New York syndicate has made application to the Edgewater, Staten Island board of village trustees, for a charter for an electric railroad to run from Sea avenue, Clifton, along the South Beach boulevard to New Dorp.

Mr. Edison had a pleasing celebration of his 42d birthday on February 11th. When Mr. Edison entered the great library in his laboratory, the two or three small tables, as many odd chairs, a triplet of well worn rugs, and a dismantled clock, which had constituted the only furnishing of the big room outside the book shelves, had disappeared, and instead was an array of luxurious furniture which would break the resolutions of a mediæval ascetic. Seven heavy, carved oak tables, a score and a half of handsome leather-covered oak chairs, each bearing a carved monogram of "T. A. E."; a big gas-log burning brightly upon a pair of fantastic wrought-iron andirons, and the old clock-face, with new hands and regulated by wire direct from Washington, were the principal

changes. That which claimed Mr. Edison's attention most was a full sized phonograph of gold, silver and steel, provided with the new automatic regulator for adjusting the pressure of the stylus upon the wax cylinder.

Mr. T. A. Edison has been making preparations for the last six months for an exhibition in the Paris Exposition Universelle. He has been allotted 8,000 square feet of floor space in the main building, and here he will show models of all his inventions in telegraphy, telephones, electric lighting, and the phonograph. The principal feature of the exhibition will be an enormous model of an incandescent lamp, 40 feet high, the globe being composed of no less than 20,000 incandescent lamp bulbs. The effect, when the light is flashed, will be wonderfully brilliant, illuminating the entire main building. On either side of this exhibit will be the French and American flags worked out in colored incandescent globes.

The *Times* has the following editorial in relation to the work of the Board of Electrical Control :—

"The work of the Board of Electrical Control, which has been prosecuted against powerful obstacles, is beginning at last to bear fruit. The Broadway and Sixth avenue subways are now being utilized by the Western Union, the fire department and the Manhattan Electric Light Co., and the cheering promise is made that by the 1st of May, all the poles and wires in upper Broadway and Sixth avenue, will probably disappear. Other electric light companies are ordering cables and preparing to make use of the subways. Much of this cheerful prospect is due to the firm stand taken by Mayor Grant, who began his administration by accepting the presidency of the board, and declaring that the law should be enforced. With the city government pledged to the execution of the subway law, those companies which had hitherto defied the Board of Electrical Control have found it politic to fall into line and bow to the inevitable, and the result promises to be the abatement of the overhead wire nuisance in a reasonable time. This will be a victory for the board which it has well earned by its persistent policy of insisting on the execution of the law ; it will be a victory for the people who have for years demanded the burial of the wires, and it will prove a victory for the companies against themselves in the end, for the cost of putting the wires out of sight will be more than repaid by the saving in expense for repairs after every heavy storm."

The contractor who is putting down the Bentley-Knight conduit for the Fulton street road has delayed work for the past few weeks. It is alleged that the delay has been caused by the difficulty in securing right of way for a short distance, and it is now given out that the road will be ready by April 1st. The Bentley-Knight company have completed 13 cars for the Fulton street road, and seven more are being constructed.

At each session of the Legislature a bill makes its appearance giving permission to the surface street car lines to use cable power, but although powerful influences are kept at work it has always met with defeat. The mayor has sent a protest to the Legislature against the bill, stating that he is now considering the question of a solution of the rapid transit problem.

The meeting of the electrical section of the American Institute was held February 6th at the factory of the C. & C. Electric Motor Co., which was formally opened for inspection. The factory is fireproof and admirably equipped throughout. Indeed, it may be doubted if such facilities maintain anywhere else. A 50,000 watt dynamo in the basement supplies power, which is carried by wires to small motors placed so as to secure the minimum of economy.

In connection with the small motor industry which appears to be assuming such large proportions, a motor just placed on the market by the Elektron Manufacturing Co., designed by Mr. Frank A. Perret, is deserving of special mention. The lamination of the field is accomplished in an ingenious manner, and a comparatively high efficiency secured thereby. The armature is wound with double covered silk wire, and there is no lead to the brushes. The mechanical as well as electrical details are most carefully worked out.

Professor Daniel C. Eaton, of Yale University, has presented a remonstrance to the Connecticut Legislature against granting the privilege to a New Haven street railway to string overhead wires, on the ground of danger to the public. Professor Eaton advocates the use of storage batteries.

A terrific explosion occurred in a subway man-hole early on the morning of February 11, at Pearl and Wall streets. It is thought that the heat from the steam heating pipes was indirectly the cause, the insulation of the wires being badly damaged, permitting them to come together and ignite the accumulation of gas.

NEW YORK, February 21, 1889.

.... IN the eternal cycle which with God began, force in a protean form remains constant; and whether it is applied to the uses of man, or whether it is expended in some useless or injurious effect, depends upon how nearly imperfect man can obey the laws of nature in dealing with it.—*E. N. Dickerson.*

PHILADELPHIA.

Novel Installation in the Tabernacle Baptist Church.—Leaving for the Chicago Convention.—Proposed Electric Railway.—Agitating Electric Light for Several Small Cities.—Electrical Patents.

THE Tabernacle Baptist Church on Chestnut street above 18th, which has been closed for several months past while undergoing repairs, was reopened yesterday. The edifice is to be lighted by means of 120 Edison incandescent electric lights, distributed over its extent, placed there under the supervision of Messrs. Walker and Kepler, the agents of the Edison company in this city. The principal grouping of these lights is in a 36-light chandelier in the centre of the church. The entire lighting system is divided into eight sections, each independent of the other, and capable of being lighted or dispensed with separately. On and about the pulpit there are 10 lights on an independent circuit which are operated by the officiating minister who, when desirous of doing so, can light them or put them out by merely touching a button placed conveniently at hand. The organ is operated by a 1-h. p. Sprague motor controlled by the current from the Edison plant. The motor of the organ is so arranged as to produce the most satisfactory results, practical people declaring that its action is superior to that of any former methods employed. There are but 12 gas jets in the entire church. The beautiful fixtures were a present to the congregation from Mr. E. H. Johnson, president of the Edison Electric Light Co., of New York, who formerly resided in this city and was a member of the Tabernacle Church. The church has now one of the handsomest interiors of any in the city. The Edison company have now a large number of lights in operation in this city, and are constantly adding to the number. The Drexel building is supplied with 2,300, the immense sugar refinery of Harrison, Frazer & Co. has 2,900, the Fidelity Trust Co. have 300 lights operated by a plant of their own. In a short time the Bullitt building will be lighted by some 1,600 lights, the City Trust building by 270, and the Keystone bank by 300. In addition to these there are now in operation, lights in a large number of stores in Market and Chestnut streets, as well as private residences on Walnut street.

A number of representatives of the electric light companies in this city left on the Chicago limited express from Broad street station yesterday to attend the convention of the National Electric Light Association, which opens in the Exposition building, in Chicago, on next Tuesday morning. A large number of representatives from New York were on the train, and others will be picked up at Harrisburg and Pittsburgh. Among those from this city were supervising engineer W. D. Marks, president L. D. Brown and secretary Henry G. Bryant, of the Edison company ; John S. Muckle, of the Westinghouse company, and Andrew J. DeCamp, of the Brush company.

For some months, plans for the construction of a passenger railway to take in Haddonfield, Merchantville and the several small towns between them and Camden, N. J., have been under discussion, and it is said that in a few days they will take form. It is stated that negotiations are already pending for the purchase of the old horse railway, with a view to introducing electric motors on at least a part of the system.

A large meeting of citizens of Holmeville, Eden and Langhorne, Bucks Co., Pa., was held at the latter town recently for the purpose of considering the introduction of electric lights into those places. A company was organized to secure a plant, and $13,000 worth of stock was subscribed for. Bordentown, N. J., is also agitating the electric light question.

According to the brokers of this city, capitalists and speculators are turning their attention to electric stocks now.

The following patents were issued to Philadelphians last week. Rudolph M. Hunter, dynamo-electric machine, also apparatus for heating cars by electricity. Francis J. Clamer and J. H. Hendrickson, protecting negative plates of electrical batteries.

PHILADELPHIA, February 18, 1889.

BOSTON.

The Police Signal System.—The Electric Club.—The Electric Light Interests at Dedham.—The City and State Government's Interest in Electrical Industries.—Matters of Interest Connected with Electrical Traction.—The Snow Storm.—The New Building for the American Bell Telephone Co.—Petition of American Bell Company for Increase in Capital Stock.—The Bell Telephone Co.'s Exhibit for the Paris Exposition.

IT was expected that before this time the police signal system would be in full operation in all sections of the city. But difficulties have been experienced and delays occasioned, so that the work of construction, which is conducted by police-lieutenant Goodwin, will not be completed for a few months yet. The police districts which are still without the system are division 2, city proper ; division 7, East Boston ; division 10, a part of Roxbury ; division 11, Dorchester ; division 12, City Point, South Boston ; division 13, West Roxbury ; division 14, Brighton, and division 16,

Back Bay. The wires and boxes are about ready for use in East Boston, Roxbury, Dorchester and Brighton, and the system will be operated in those divisions just as soon as stables and wagons can be built. The work of construction is slowly going on in South Boston (City Point) and in West Roxbury and the Back Bay. According to Lieutenant Goodwin, the board of police has not decided as to the advisability of having a patrol wagon for the Back Bay. The boxes will be a great adjunct to the police service of the business district, for it should be remembered that they are not only of value in troublous times, but are excellent preventives of negligence, every patrolman being required frequently to visit the boxes on his route, send in the "on-duty" call, and telephone unusual incidents to the station house. By their aid a police sergeant can sit in the station house and know at almost any time of the day or night where an officer can be found. Should a wagon be needed, it can be called from another division.

About 200 keys of signal boxes have been issued to as many citizens by the captains of the different divisions. The keys are given to citizens who make application for them, but these citizens must be personally known to the police as men of good character and of excellent standing in the community. Thus far but few citizens who possess keys have had occasion to signal for the police.

The Boston Electric Club, at their new quarters, No. 7 Park street, was entertained on the evening of the 6th inst., by Hon. Richard J. Monks on "The History and Growth of Artificial Lighting." Mr. Monks exhibited several valuable and curious appliances used, particularly in ancient artificial lighting, not the least interesting of which was a finely wrought copper lamp of Persian origin, and claimed to be at least 1,000 years old. A part of the address was identical with that given before the Boston University two years ago. The concluding portion referred more particularly to electric lighting, and was interesting. Subsequent to the address the members and friends passed a pleasant hour or two in social intercourse in the new rooms.

The following items concerning Dedham, this state, are a fair sample of what is going on in electric light matters in the towns of New England :—

The Dedham & Hyde Park Gas and Electric Light Co. started up its electric light plant in Dedham, on the night of the 30th ult., lighting up its office and the office building. The company is now prepared to supply electricity for public and private use as soon as permission is granted by the selectmen to extend their wires through the town.

The selectmen gave a hearing on the 7th inst., on the petition of the Dedham Gas & Electric Co., for leave to erect posts and wires in the highways. After listening to the arguments of George Fred Williams, counsel for the company, the matter was laid on the table, as a similar petition had been filed earlier by the Dedham Electric Light Co. It was decided to hold a public meeting in the lower Memorial Hall, next Thursday evening. The Dedham Gas & Electric Light Co. illuminated Memorial square in a brilliant way by means of five electric lights placed in front of its office and the adjoining buildings.

There was a hearing before the state committee on manufacturers on the petition of the Dedham Water Co. to furnish electric light and power. John R. Bullard, treasurer, said it was the purpose of the company to supply electricity by the underground system. There were two other petitions before the selectmen, but he believed that it was for the interest of the town to have as many competitors as possible. One of the petitioners was the Dedham Electrical Co., which has no visible capital and the other the Dedham and Hyde Park Gas Co. Both these propose using the Thomson-Houston system. W. A. Feltee, manager of the gas company, said that two of the directors of the water company opposed the petition before the committee, and that it was presented without the consent of the stockholders. The legislature, he said, recognized the right of gas companies to furnish all manner of lighting, and its company had its plant ready and could put it in operation within 30 days.

Our solons at the State House are full of recommendations concerning electrical matters—a bill to regulate telephone rates ; one that Frank W. Ames and others be incorporated as the Boston Electric Elevated Railroad Co.; one by Mr. Gleason, of Plymouth, as to authorizing the gas commissioners to issue temporary licenses for the laying of electric light wires ; one by Mr. Farren of Stoneham, as to examining the effect of electric street car wires upon the safety of life and property.

Our electric railway from Park square out to Brighton, continues to be the pet of the town ; it had its first trial with a snow storm on the 20th ult. Unfortunately the storm found the West End road not fully prepared for the contest, as the electric ploughs and track sweepers are not yet finished, and arrangements for the use of the ordinary horse ploughs over the 13 miles of electric track were not completed until the middle of the forenoon. The first cars from Oak square ran all right until the conduit system was reached on Beacon street, the little rail ploughs and brushes sufficing to clear the track in good order. The conduit, however, bothered some, and car after car reached it only to stop, until eight cars were standing all in a bunch. The ice which filled the little slot was finally dug out by men with shovels and picks for some little distance on Beacon street, and the cars then moved along rapidly and without trouble, and the first car reached Park square at nine o'clock, rapidly followed by others. In the meantime a common street railway plough, drawn by six horses, was sent over the track to Coolidge corner, so that on the return the electric cars spun along merrily. The overhead system appears to have been the most reliable under the disadvantages of this storm ; but when the electric snow ploughs, with their specially constructed mechanism for clearing the conduit, are ready for use it is believed that the entire line will work satisfactorily. As horse cars were all running with four horses after the tracks had been cleared by the ploughs, while the electric cars run along easily with heavy loads and cleared their own tracks, the advantages of electricity were evident.

As a precaution against stoppage by day on account of the snow fall, the electric cars of the West End, Brookline and Brighton lines were run all night on the 11th, and in the morning following the tracks were in good condition for travel. Cars were run at frequent and quite regular intervals throughout the forenoon, and were well patronized. As the employés become more and more familiar with their new duties, the absence of hitches becomes more apparent. The only obstruction was the usual one, not caused by the storm. At about 11.15 o'clock four cars were stopped five or ten minutes on the conduit system at Chester park and Beacon street, by the burning out of two "ploughs." These were taken aboard, and the derelict cars were propelled by the cars following them until the overhead section was reached, and they resumed their course.

It is proposed to build an electric road from Lynn to Nahant, and the $60,000 required for the purpose has been subscribed, several prominent residents of Lynn and Salem being interested in the enterprise.

The American Bell Telephone Co. have petitioned the legislature for an amended charter, to wit : that their capital stock may be doubled, increased from $10,000,000 to $20,000,000. In consequence of this, the stock has advanced from about 207 to 225. The work upon the new building for the telephone companies, progresses slowly; the foundations are being solidly laid. A glance at a perspective view (in water color) of the new building, discloses a tall, massive and fine facade fronting on two streets, Milk and Oliver. The building will contain the American Bell offices, the New England Telephone & Telegraph Co.'s offices and the Boston Telephone Exchange, the Long-Distance Telephone offices, and leave rooms and offices for rental.

The Bell company have completed a very interesting exhibit of telephones and telephonic apparatus for the Paris exposition, comprising early telephones, bells, Edison mototograph, etc. The exhibit will be in charge of Mr. W. D. Sargent, of Brooklyn, N. Y.

BOSTON, February 16, 1889.

CHICAGO.

Death of Mr. George L. Phillips.—Temporary Stoppage of the City Lighting Service in the Town of Lake.—Two Trains on the Chicago, Milwaukee and St. Paul Railway Equipped with Electric Light Plants.—Lighting the North Side Street Cars Automatically as the Tunnel is Entered.—A Rumor that the Van Depoele Company Proposes Introducing an Alternating Current System. The City Lighting Plant for Elgin, Ill.—The Matter of Reduction of Telephone Rates in the Hands of the Legislature.—The United States Electric Lighting Co. Awarded the Contract for Increase of Plant in Court House.—Electrical Interests at Lake View.—The Cushman Company Announces an Appeal to the Supreme Court.

GEORGE L. PHILLIPS, president of the Chicago Telephone Co., and the Central Union Telephone Co., died of malignant typhoid fever at his residence in Edgewater, a suburb of Chicago, January 29th. The circumstances were unusually sad. Mr. Phillips, soon after the holidays, left Chicago, to accompany his daughter, a young lady 17 years of age, to New York, where she was attending school. Father and daughter were at the time apparently in perfect health. After a short stay in the east, Mr. Phillips returned to his home. He felt slightly ill on his journey westward, and as soon as he reached Edgewater typhoid fever of a malignant type was developed. News was soon received that Miss Phillips was seriously ill of the same disease in New York. Mrs. Phillips immediately left for the east, and a week after she had reached her daughter's bedside the latter died. The remains were taken to the family lot in Dayton, O., for burial. Death had afflicted the family of Mr. Phillips' brother in Dayton, just before this time. Two children had died suddenly. Mrs. Phillips accompanied by her brother-in-law, Charles A. Phillips, hastened to Edgewater. Mr. Phillips' condition was most precarious, and the news of his daughter's death was carefully concealed from him. He grew steadily worse, and on the fourth day after his wife had reached home, succumbed to the disease. He leaves a wife and four daughters.

Mr. Phillips was born in Dayton, in 1845, and was the son of T. A. Phillips, a cotton manufacturer in that city. He attended

the University of Michigan, at Ann Arbor, in the class of '67, but left before graduation to enter the army. He subsequently entered his father's business and was a member of the firm for several years. During this time he organized the Dayton American District Telegraph Co. and the Cincinnati American District Telegraph Co He continued to be president of the latter corporation until his death. He organized the Dayton Telephone Co., and his services there were so efficient that he received the appointment to take charge of the Boston Telephone Exchange. Subsequently he acted as assistant general manager of the American Bell Telephone Co., with headquarters in Chicago. He left this position to take a European tour. He returned in 1886, and was elected president of the Central Union Telephone Co. A little over a year ago he became president of the Chicago Telephone Co.

It has been noted in the letters from Chicago, that the last year was one filled with controversies between the city government on the one hand and the Chicago Telephone Co. on the other hand. The city council endeavored to regulate the business of the corporation and the latter very naturally resisted. The company was without an ordinance warranting it to transact its business in the city. The year for the company was a struggle against encroachment by the aldermen. The duty of solving the problem fell on Mr. Phillips, and he secured a victory by obtaining a franchise without conceding any of the essential points for which the company had been fighting.

Mr. Phillips was a man of splendid physique, and full of energy. Personally he was of a kindly nature. On first acquaintance his manner was extremely formal and unbending, but behind an exterior rather severe he preserved a feeling of kindness and friendliness. His associates in the two companies of which he was president, were attached to him by the strongest ties of friendship, and they are of one opinion that he was the ablest executive officer of a telephone company in the country.

In speaking of the death of Mr. Phillips, an officer of the Central Union Telephone Co. said to the representative of the ELECTRICAL ENGINEER:—"I have been connected with corporations for 30 years, and have been associated with a number of able executive officers, but I have never seen such a president as Mr. Phillips. He was a man of the most marked executive ability and he had a large fund of knowledge, tact, experience and talent which enabled him to grapple successfully with the many perplexing problems peculiar to telephone work. His talent in this direction was developed at a time when there were few men in the country who thoroughly comprehended the business, so that his services have been of extraordinary value in connection with the development of telephony in this country. This company and the Chicago Telephone Co. have suffered a great loss. His place can never be filled. His death comes to us all as a personal bereavement."

There has been a curious state of things in the Town of Lake, which adjoins Chicago on the southwest. Its streets are lighted by arc lights operated from the circuits of the Chicago Arc Light and Power Co. The trustees of the town became engaged in a controversy with the gas company, and refused to put any money into the illumination fund lest it should be drawn upon by that corporation. The electric light company suffered at the same time, as there was no fund which could be employed in defraying its bills. The electric light company's bill grew greater and greater. The officers received in answer to their demands for money, letters assuring them of the continued respect of the trustees, but nothing in the form of checks. Matters soon came to a crisis. The trustees were informed that unless money were forthcoming on a certain day the electric light service would be discontinued. The trustees still hesitated and the supply of current was shut off. A murder was committed and several burglaries followed, and as a result the trustees found their constituents criticising them in no uncertain terms. A compromise was effected. A large sum of money was paid to the electric light company, and the Town of Lake again rejoices over the fact that it has its streets well illuminated.

The Chicago, Milwaukee & St. Paul Railroad Co. has adopted on two of its trains running into Chicago, an electric light system. Each plant consists of an Eickemeyer dynamo, a Brotherhood engine and a set of storage batteries. Up to midnight the lamps throughout the train receive their current directly from the dynamo. After that time the storage batteries carry the load. The installations were made by Leonard & Izard. The system will probably be extended to other trains in the near future.

A cable car on the north side, has been wired for incandescent lights. The intention is to illuminate the car as it passes through the La Salle street tunnel. The current will be conducted to the car by an overhead wire, along which a trolley wheel will run. Connection will be made automatically as the car enters the tunnel and will be broken as it passes out.

There is a rumor current that the Van Depoele company proposes to put an alternating current system on the market at an early day. Representatives of the company neither deny nor affirm the report.

Mention has been made from time to time of the fight over the contract for the electric light plant for the city of Elgin, Ill. A plant has been in use there for several years, but when the council asked for bids there was the usual scramble for the contract. Charges of bribery too were made without hesitation. The contest is now over. The council has voted to buy the local plant and retain the tower system of lighting.

Like most legislatures throughout the country, the lawmaking body at Springfield, Ill., has wrestled with the "telephone question" in all its details. The legislators are possessed of the idea that they are face to face with a problem which demands instant solution. A number of bills contemplating a general reduction in rates has been introduced. All the measures are of substantially of the same character. They propose reductions according to which rentals would range from four to six dollars per month. The bills are penal in character. The offense according to the measures for violating the provisions of the proposed acts by overcharge is a misdemeanor. One bill has also been introduced delegating to municipal councils the right to regulate telephone rentals. It is scarcely necessary to remark that the Chicago Telephone Co. is especially aimed at by all the legislative marksmen. The rentals in Chicago are $125 per year, and if any of the proposed measures become a law it would be the greatest sufferer. Officers of the company state that rather than submit to the conditions of most of the bills the company will cease to transact business. It should be added that they do not anticipate the passage of any of the sweeping bills.

The United States Electric Lighting Co. has been awarded the contract for increasing the incandescent plant in the Cook County court house, from 1,000 lights to 1,500 lights. The dynamos now in use will be replaced by larger generators.

A bill has been introduced in the legislature at Springfield, authorizing the city of Lake View, which adjoins Chicago on the north, to establish a municipal electric light station or gas works.

The Lake View Telephone Exchange of Chicago, has been incorporated. The capital stock is $72,000, and the incorporators are L. D. Tuttle, J. M. Cleaver and W. F. Wiemer.

The Cushman Company, of Chicago, will carry its appeal from the injunction granted by Judge Blodgett in favor of the Bell Telephone Co., to the United States Supreme Court. A motion for a rehearing was denied by Judge Blodgett recently.

CHICAGO, February 20, 1889.

SAN FRANCISCO.

A Society of Electricians in San Francisco.—The Phonograph Company.—State Legislation concerning Telegraph and Telephone Companies.—Rivalry of the Western Union and Postal Telegraph Companies.—Pneumatic Tubes to be Employed for Local Delivery by the San Francisco Post Office.

SAN FRANCISCO has determined to have a society of electricians which intends to pursue the same course adopted by the eastern societies. It was organized permanently last week by electing N. S. Keith president, and O. Brooks vice-president, adopting a constitution and by-laws similar to those of the Buffalo, N. Y., organization. It is to be hoped that good results may ensue from thus associating, interchanging ideas and discussing methods and theories. Over fifty men have already signed the roll, and it is intended to merge this organization with that of the Mechanics Institute of this city, thus placing an excellent library at the service of the embryo-electrical engineers.

A determined effort is being made to float the phonograph stock here; all the clerks in the Telephone and District offices have received shares gratis.

The legislature of this state is trying to make telegraph and telephone companies common carriers, and thereby hold them responsible for all errors and omissions. Superintendent Jaynes, of the Western Union company, is most of his time at the Capitol working against the bill, but he will have a hard fight of it, as public opinion is anything but favorable to his company in this state; while his own admissions in the *Examiner* of this city a few weeks ago are embarrassing. Rivalry is running rife in this city between the Western Union and Postal companies. Branch offices are to be seen at every corner where they are *vis-a-vis*, with their banners floating in the air. A few weeks since the Western Union thought a block or two nearer Market street preferable, whereupon the Postal erased "Postal" off their window, and now it simply reads "Telegraph Office."

The efforts of the Postal company to drive the older company will only end in loss to themselves; although they are building to Los Angeles and southward and expect to reach that city in a few weeks. They are getting there when Southern California is settling down to a fundamental basis, the "boom" having subsided. They will find, too, that when the Western Union will use Wheatstone to Portland, Oregon, and to Los Angeles, that the old company will reduce rates to such a proportion that the young company cannot afford to employ a decent operator at a respectable salary. At least it is presumable that such would be the tactics of a great rival to freeze the weaker out. There is some talk of a bill in the legislature making all rates within the state 25 cents for twenty words and five cents for every extra ten words.

Manager McRobie, of the Western Union, has done herculean work since his arrival here. Manager, cashier and general information bureau, he has worked far into the night and to him the public is indebted for a prompt and more accurate service than they have been accustomed to heretofore.

The pneumatic tube system will soon be introduced into this city for delivery of letters in conjunction with the post office department. This will prove a crusher to district systems, and it is about time the public was relieved of this incubus.

SAN FRANCISCO, February 16, 1889.

MONTREAL.

The Carnival; Electric Illumination of the Ice Palace.—The Brush Incandescent System in the New Building of the New York Life Insurance Co.—The Edison Company to Light the New Temple Building.—The Royal Company to Light the Imperial Bank Building.—Other Electric Lighting Notes.—Success of the Westinghouse Plant at Cornwall.—Train Lighting on the International Railway.—The Federal Telephone Co.

THE excitement of the Carnival is over, and the usual quiet reigns again. As a contemporary remarks in an opening address, "We are a hyperborean people of cheerful outward appearance, but are in reality wrestling with an unfavorable climate to make a living."

The electric lighting of the Ice Palace was very effective; 50 arc lights illuminated the interior, the castle presenting a beautiful opal surface at night, well worthy a trip to Montreal to see. The climax was reached in the bombardment of the castle. At nine o'clock 1,500 snow shoers, bearing torches, wound down from the mountain, and on approaching the castle commenced the attack, discharging volley after volley of Roman candles, sky rockets and colored lights. The garrison made a stout resistance with like weapons, but after 20 minutes' resistance were compelled to capitulate.

The New York Life Insurance Co. are building a handsome eight-story brown stone office building on the Place d'Arms. It is to be lighted by the Brush system of incandescent lighting. Wm. B. Parmelee is installing the plant, which will consist of 810 lamps. The wiring is of Grimshaw wire throughout. The dynamos are to be run by two Mackintosh and Seymour compound engines of 60 h. p., and the steam will be supplied by three Babcock and Wilcox boilers. The building and installation will be one of the most complete in the city.

The Temple building being erected on St. James street, is being wired by the Edison company for 680 lamps.

The Imperial Insurance Co.'s building, remodeled from the Consolidated Bank building has been wired by the Royal company for 575 lamps.

The Edison company report sales of 75 lights to the *Free Press*, London, Ont., and a 10 h. p. motor to Patterson and Corbin, St. Catharines, Ont. The 600 lights mentioned in last month's letter sold by the Edison company were put in the Long Point (Quebec) asylum.

The Royal Electric Co. report sales of 40 arcs to the London, Ont., company, 35 arcs to the St. Catharines company, 50 arcs to the Quebec company and 25 arcs to the Moncton, N. B., company.

The Westinghouse company at Cornwall, are very much pushed to keep up with the demands for their light. They are peculiarly favorably situated, in that the local gas company recently adopted water-gas and the incandescent comb system of gas lighting. Users, especially cotton factors, are afraid the comb will break and fall into the fabrics below, igniting them. The insurance companies have also increased the rates for its use, and consequently the gas company are in a very bad way.

The City of Toronto has awarded the contract for an increase of 200 arc lamps to the present company, the Toronto Electric Light Co. The International Railway Co. (government road) are preparing to light their trains running out of Quebec by electricity.

The Craig people who have a municipal plant in St. Cunegonde, a suburb of Montreal, have extended their system to Côte St. Antoine, another suburb, and are to light that municipality.

The Federal Telephone Co. are pushing their system and propose to be in operation in May.

MONTREAL, February, 20, 1889.

.... WHEN the great Creator, in the construction of this world separated the carbonic acid of chaos into its two constituents, and stored away the carbon for the use of man, while the oxygen was liberated in the envelope of the earth, ready to again combine with the carbon, and again produce the force which had been expended in disuniting them, the problem presented to imperfect man was the production of so much force, by again uniting these dissevered elements, as had been expended in separating them. The plain injunction given to him is: Be economical of these resources, for they are limited.—*E. N. Dickerson.*

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall street, New York city.*

[103]—As it has become the fashion amongst our best technical colleges to found a course in "electrical engineering," let us heartily applaud the recognition of the demand for higher training in our profession. Then let us examine the treatment that the electrical course should receive and is receiving.

Ten years ago the most sanguine mind could scarcely have conceived the incandescent electric light as a public necessity, and electric transmission of power was unborn. Since 1880, the growth of the industrial applications of electricity has been solid and continuous. Gathering new vigor each year they have rapidly gained a high rank amongst the industries first in utility and public favor, and amongst those producing dividends on invested capital. The magnitude of the growth can be understood, and the situation grasped only by those who are engaged in helping it forward—the practical men and engineers. Those not in intimate contact with the profession tell us "all mechanical engineers are electrical engineers," which is all folly. That an "electrical engineer must first be a mechanical engineer" has the ring of truth, for he must be a thorough electrician with the instincts of a mechanical engineer.

The installation of profit making electric plants that will embrace the necessary factors of safety, convenience and economy in operation, with the least original outlay for plant, as fully requires the skill of a specially trained engineer as any undertaking of the civil or mechanical engineer. His training must be founded on the broad basis of general engineering, but in practice he must be a specialist—an *electrical* engineer.

The basis for founding courses in electrical engineering is evidently good, but our colleges apparently fail to grasp the distinctive features of the profession. It is usually tacked to the department of mechanical engineering or of physics, and in consequence either does not receive due attention or active practical treatment. The industrial applications of electricity are of sufficient magnitude to demand skilled engineers trained in a college department founded purely for instruction in electrical engineering, where the best engineers are given to making the instruction cover the demand, causing it to be practical and useful. Let the electrical engineer take a thorough, distinctive training, at the end of which he can stand for his profession as an E. E.; not a pseudo mechanical engineer, nor a bachelor of all the sciences.

D. C. JACKSON.

LITERATURE.

Fortschritte der Elektrotechnik. Unter Mitwirkung von Dr. M. Kiliani und Dr. E. Pirani herausgegeben von Dr. Karl Strecker. Erster Jahrgang. Das Jahr 1887. Berlin, VERLAG VON JULIUS SPRINGER, 1888.

THE pains-taking labors of Dr. Strecker and his able assistants, together with the enterprise of Herr Julius Springer, are giving to professional electricians and students a work of the utmost value in the Fortschritte der Elektrotechnik, of which four parts, covering the year 1887, have been in our hands for some months.

The work is a systematic guide to a large mass of contemporaneous electro-technical literature in German, English, French and Italian; the scheme including a compilation of titles—of papers, articles and notes—from leading electrical, engineering and other scientific periodicals, proceedings of technical and scientific societies, and from German, English and American patents; followed by brief descriptive notices of the most important of them.

The material of the work is classified in five sections, and 17 sub-divisions, namely :—

Section A.—*Electro-mechanics.*
1. Dynamo-machines, Electro-motors, Regulators.
2. Distribution and Conduction.
3. Electric Illumination.
4. Electric Transmission of Power.
5. Various Applications of Electricity.

Section B.—*Electro-chemistry.*
6. Primary Batteries.
7. Secondary Batteries.
8. Applications of Electrolysis.

Section C.—*Electrical Communication and Signaling.*
9. Telegraphy.
10. Telephony.
11. Electric Signals, Registering Apparatus and Clocks.

Section D.—*Measurement and Scientific Research.*
12. Galvanism (current electricity), Current, Potential and Resistance.
13. Magnetism, Methods and Instruments of Measurements, Induction, Self-induction and Capacity.
14. Lamp Measurement, Photometry, the Electric Arc.
15. Electro-chemistry, Electrolytes, Polarization.
16. Physical Researches in Electrology.

Section E.—*Terrestrial and Atmospheric Electricity.*
17. Earth Currents, Lightning Rods, Statistics of Thunder Storms and Lightning Strokes.

The references are numbered *seriatim* and amount to no fewer than 4,461 for the year 1887, and are followed in the fourth and last volume for the year by a list of 32 new books, with references to reviews and notices of each, and descriptive notes on the part of the authors of the "Fortschritte."

In the arrangement of the book the list of references comes first in each section and is followed by the notes of description or comment, each of the latter being numbered in the margin to correspond with its reference in the title list. Many of these notes are extended and in some cases include illustrations. A subject index and an index of authors are furnished in the last quarterly volume for 1887. The information contained, classified and arranged for use in this periodical publication can not fail to be extremely useful not only to students and investigators, but to practical electricians and electrical engineers. It should find its way into every electrical library.

It will be of much value to solicitors of patents and patent lawyers in facilitating researches into the "state of the art" in important cases. Such a summary of electrical literature, say of 1879, would be highly prized at this time.

Treatise on Patent Estate. Comprising Nature, Conditions and Limitations of Interest in Letters Patent. By THOS. B. HALL. Cleveland: INGHAM, CLARKE & Co., 1888.

It is a great pity that the author of this useful and otherwise generally excellent little book, of which the profession and the public have long felt the need, could not have written it in English, and thereby materially increased its sphere of usefulness, and his reputation as a text-book writer. We remember few law books, the examination of which has so much interested us, and yet at the same time has caused us to feel so keenly our ignorance of foreign languages. It is a still greater pity that Mr. Hall's publisher could not have published an English translation of this work for we feel sure that it would have met with a larger demand than the original. It passes comprehension how a modern law publisher could have seen fit to publish this book in its present form, were not the material treated comparatively novel, the need of a treatise on the subject long felt, and the method of treatment substantially satisfactory. For the publishers of this book there can be no excuse. For the author there can be but two excuses; either his publishers have published what he chooses to call "developed outcome of notes made for personal reflection" (assuming that one knows what that means) without giving him an opportunity of revising them, or else he has sat so long at the feet of the German jurists of the last century that he has been unable to shake off the formalism of their style and method of oration. Against this second excuse militates this author's method of quoting from the Pandects, on pages 100 and 101. A German Pandectist would not have failed to give the precise place where the citations were found. Nevertheless the book is extremely useful to every patent lawyer. Its arrangement is concise and it covers a peculiarly interesting and almost untrodden field. For the practicing lawyer it is a handy series of briefs ready made, upon the subjects treated of in the several chapters. With this book in the hand, assisted by a good dictionary, the practitioner has a much more general synopsis of the law of property in patents, than it has hitherto been possible to find. Each topic is treated carefully and conscientiously. English and American cases are cited and liberal quotations given, and while we do not agree with the author in some of his views, we cannot help praising his concise method of arrangement. The book contains five chapters:—The Object of our Patent System; Property Rights in Patents; Profits of Property Rights in Patents; Partition of Patents, Accounting between Part Owners; Limitations of Sectional Grants. The reviewer is aware of no work in which any attempt is made to treat systematically these subjects, and particularly those of the second and seventh chapters. The scope and extent of property rights in patents is fully discussed, and cases are freely cited, but the conclusions reached is unsatisfactory, in that as a result of his reasoning the author concludes that "property right of patents would seem to rest in claim in law, to debarment in fact of making, using and vending the invention."

Judge Taney expresses the author's meaning much more clearly in Bloomer *v.* McQuewan, 14 How., 539, where he says: "The franchise which the patent grants, consists altogether in the right to exclude every one from making, using or vending the thing patented, without the permission of the patentee. This is all he obtains by his patent."

In considering the profits resulting from the exercise of patent rights, what the author chooses to call "profits of patent" an attempt is made in the third chapter to distinguish between a so-called "debarment in law of making, using and vending an invention," and a "debarment in fact." The latter the author claims is produced by the former, and being as he says a "primary product though incorporeal and negative, yet being a debarment in fact," is more appreciable by bodily sense than the legal abstraction that produces it." This primary product or incorporeal right is capable of being converted into money, and hence a property attribute is given to a patent. The distinction would seem to be artificial, not founded on sound reasoning and quite needless, as the mere money value of a patent lies in the property itself without reference to the particular nature of the same. The author's views are, however, interesting, and worthy of careful perusal.

The chapter on limitational grants, handles as satisfactorily as is possible in such small compass a subject which bristles with uncertainties, and is a very useful digest of the cases on this subject. In our opinion, a serious mistake has been made in citing Supreme Court cases, in the body of the book from Whitman's Patent Cases, and not from the standard reports. The book is well printed and excellently indexed, and is worth its price many times over to every patent lawyer.

PAMPHLETS AND CATALOGUES RECEIVED.

Bulletin of the Agricultural Experiment Station, Cornell University: College of Agriculture, III. and IV., November and December, 1888. Contents, III.—The Insectary of Cornell University; On Preventing the Ravages of Wire-Worms; On the Destruction of the Plum Curculio by Poisons. IV.—Growing Corn for Fodder and Ensilage; Economic Seed Manure.

Second Report of the Board of Electrical Control for the City of New York—December 21, 1888. Contains Statistics of Subway Work; Rules and Regulations of the Board and some illustrated descriptive matter. 79 pages, including Appendices.

Weston Standard Direct Reading Voltmeters and Ammeters for Direct Current Circuits. Weston Electrical Instrument Co., Newark, N. J. A circular descriptive of Mr. Weston's new voltmeter with list of the several types offered, and an announcement of the near completion of a similar series of ammeters.

Illustrated Price-List of the Taper Sleeve Pulley Works, Erie, Pa. Gives descriptions of pulleys, couplings, etc., handsomely illustrated, with priced lists of the various sizes and styles supplied.

POINTERS.

.... THE man of true genius never lives before his time; he never undertakes impossibilities, and always embarks in his enterprise at the suitable place and period. Though he may catch a glimpse of the coming light as it gilds the mountain top, long before it has reached the eyes of his contemporaries, and though he may hazard a prediction as to the future, he *acts* with the present.—*Joseph Henry.*

.... IN the history of the development of the steam engine one curious phenomenon deserves to be mentioned, and that is the attack upon James Watt and his laws of steam by the government of the United States during the rebellion, when vast sums of money were expended in building steam engines. At that time the government officially pronounced its judgment of condemnation upon the laws of Watt, and published that judgment in a book which was distributed to the engine builders and engineers of the country as the authoritative decision of the United States.—*E. N. Dickerson.*

.... THE scientific recluse, shut up in his own thoughts, as in a cell, and magnifying the grandeur and importance of his own work at the expense of that of others not exclusively devoted to research, is more nearly a modern imitator of the monastic original than most persons are apt to suppose.—*Alpheus Hyatt.*

.... STUDY the laws of nature, which are the thoughts of God, and do not attempt to rebel against them. We cannot create new laws or produce force. Obedient to these laws, work on in adapting them to the uses of man; and the time is not far distant when steam power, at the rate of three-quarters of a pound of coal an hour a horse-power—or its equivalent in petroleum—and with 95 per cent. dynamos, the electrician will take possession of the whole field, wherever horse-power is to be used for the convenience and elevation of men.—*E. N. Dickerson.*

.... THE coal deposits, when once exhausted, cannot be renewed; and the existence of civilization on the earth in its present form depends upon the supply of available carbon.—*E. N. Dickerson.*

.... THE future before men of the electrical profession is brilliant indeed. The doors were opened wide by Henry and Faraday, and already we have explored far beyond their imagination.—*E. N. Dickerson.*

NEWS AND NOTES.

THE TELEPHONE INTERFERENCE CASES.

An Important Decision by the Commissioner of Patents.

McDonough v. Gray v. Bell v. Edison.
Decided February 23, 1889.

STATEMENT.

Statement of the litigation growing out of the several interferences declared between the patents granted to A. G. Bell and the applications of later applicants; the inventions distinguished and compared with the previous state of the art, and the decisions rendered by the various tribunals in the Office considered and discussed.

1. *Gray's Petition to reopen.*

Held that the petition "is of no avail for any purpose whatever;" that Gray proposes no new evidence as to dates, nature, or the character of his own invention; that it was conclusively shown in the evidence that Gray, at the time of filing his caveat, while having a conception of the telephone, did not understand the invention, and was unable to explain the mode of its operation; that he adhered to the idea that articulate speech must be transmitted upon the multiple-telegraph principle; that he positively conceded that he did not reduce his invention to practice for a long time after the issuance of patent to Bell; that he regarded the invention patented to Bell as trivial, and called it a "scientific toy," and turned his attention to other and, in his opinion, more important inventions; that he negligently omitted to file his application for a patent until two years after the grant of Bell's patent and was then stimulated to do so only by other parties, who had acquired an interest in his inventions; and that his present petition, filed without notice to the adverse parties, was delayed for 3 years and 5 months after the decision of the examiner of Interference awarding priority to Bell, and was then accompanied by a request that it should not be acted upon until further motion was made.

2. *Charges of Fraud.*

For reasons stated, the charges in Gray's petition that Bell had fraudulently secured access to his caveat, purloined his invention, and interpolated a description thereof in his application *Held* not sustained.

3. *Priority of Invention and Validity of Bell's Patent.*

Held that the decision of Commissioner Butterworth, of March 3, 1885, was elaborately considered and deliberately rendered, and that a rehearing could only be justified upon clear and satisfactory evidence showing in such decision error in the conclusions of fact or in the application of the law, and that evidence could be produced establishing that Gray could antedate Bell's invention, that he could prove a prior conception and reduction to practice, or that, having made an earlier conception, he had diligently prosecuted it to a reduction to practice. In the absence of showing the existence of such evidence upon the testimony filed before and considered by the various tribunals in the Office, *Held* that "the award of priority of invention was justly given to Bell," and, in view of the construction given by the Office and the courts to the patent, the grant was properly issued, and the protection afforded the inventor was authorized.

4. *Extending the Monopoly.*

The public has a direct and immediate interest in the further prosecution of Gray's application for a patent. If the award of priority given to Bell can be vacated and set aside, it should only be done upon a showing of merits that would entitle Gray to a patent. Such patent would run for a period of 17 years from its date, and would dominate and control all devices relating to the telephone for another period of 17 years. The effect would be to subject the public to a renewed monopoly in all nearly, if not quite, thirty-four years. Such result would be in contravention of the spirit of the statute, and, in view of the liberal provisions of the patent system, cannot be tolerated except when the inflexible rules of law a d ju tice compel it, especially in the present case, wherein it is clearly shown that the Bell Company is the "equitable if not the legal owner of Gray's telephone inventions."

5. *Titles and Rights under Assignments.*

The Commissioner has no equitable jurisdiction over the rights of parties claiming under assignments and grants of inventions and patents. He cannot set aside or vacate such instruments, nor can he recognize equitable rights growing out of transactions between inventors and applicants and other parties. While the Commissioner is authorized to recognize formal legal assignments, and when they have been filed in the Patent Office before patent issues may give the assignee control of the management and prosecution of an application and direct the patent to issue in the name of the assignee, yet he cannot recognize equitable rights under executory or other equitable contracts; but where the relief asked, as in a petition for rehearing, is founded upon an alleged state of the title to the invention, the Commissioner possesses the power to determine the allegation as to title in order to exercise his discretion in granting or refusing the relief.

1. *McDonough's Petitions.*

As to the petition of McDonough that he be allowed to demonstrate the operativeness of the make-and-break principle, the Commissioner holds the decisions of his predecessors are conclusive on that question; that McDonough never claimed to be the original inventor of the telephone, but a mere improver upon Reis's instruments; that he accepted and still accepts the make-and-break system of Reis as the foundation of his invention; and, in view of the settled judgment of the Patent Office that speech cannot be transmitted by an instrument which operates solely by the making and breaking of the circuit, and also in view of the fact that the Supreme Court of the United States has also definitely settled this question with reference to Reis, he must regard the matter *res adjudicata.*

2. *No Interference between McDonough and Bell.*

As to the petition to reopen on the merits, the Commissioner holds that McDonough's original claim for the receiver having been rejected on reference to Bell's patent, and he submitting thereto and canceling the claim, and McDonough having been brought into the interference in consequence of the later applicants, so as to compel them to establish an earlier date of invention than himself, it follows inasmuch as there could have been no interference between McDonough and Bell alone, that when Gray and the other later applicants were defeated and taken out of the interference there could be left no contest between McDonough and Bell.

3. *Claims Voluntarily Canceled.*

Whether an applicant who has voluntarily eliminated his claims and apparently abandoned them should be permitted, after the invention has been publicly introduced and made commercially valuable, to return after 11 years and amend and claim an interference with a patent so long outstanding is a serious question, and the right to the relief should be most convincing.

4. *Petitions Denied—Insufficient Showing.*

Petitions denied because the showing is deemed insufficient to justify the Commissioner in setting aside former decisions and decrees, since he is fully convinced that another trial on the question of priority would result in another award in favor of Bell.

PETITIONS OF ELISHA GRAY AND JAMES W. MC DONOUGH TO AMEND AND TO REOPEN.

TELEPHONES.

A. G. Bell, patent No. 174,465, granted March 7, 1876, on application filed February 14, 1876.

A. G. Bell, patent No. 186,787, granted January 30, 1877, on application filed January 15, 1877.

Elisha Gray, applications Nos. 1, 2 and 3, filed October 29, 1877.

James W. McDonough, application filed April 10, 1876.

James J. Storrow and Roscoe Conkling for Bell.
Robert G. Ingersoll and Frank H. Hurd for McDonough.
M. B. Philipp and Casey Young for Gray.

Hall, *Commissioner*.

On the 26th of March, 1878, a series of interferences, lettered from A to M, were declared, and by an order of the commissioner dated March 6, 1879, case H was consolidated with case F and case K was merged in case I. By a stipulation between the parties thereto it was agreed that case No. 1 of a series of six interferences declared August 14, 1879, should be proceeded with and presented in connection with the lettered series. In September, 1880, case M was suspended by consent. Owing to the complex nature of the inventions and the variety of detail of events involved in the controversy, the issues were tried together upon the evidence taken by the respective parties, so far as it was relevant to the several issues.

The parties originally involved in one or more of the issues were A. G. Bell, James W. McDonough, T. A. Edison, E. Berliner, G. B. Richmond, E. Gray, A. E. Dolbear, A. G. Holcombe, C. E. Chinnock, C. A. Randall, F. Blake, J. H. Irwin, and G. M. Phelps. W. L. Voelker was made a party to case No. 1, November 3, 1879, and cases A and B December 29, 1879.

Prior to the date on which the cases were submitted to the examiner of interferences decisions had been rendered against Richmond (except as to case C), Holcombe, Randall, Phelps, Chinnock and Berliner, so that they were no longer parties to the controversy.

The evidence presented to the examiner of interferences was contained in five volumes: I. Testimony on behalf of Edison; II. Exhibits of Edison; III. Testimony on behalf of Voelker, Irwin, Gray, Dolbear, McDonough, Blake and Bell; IV. Vol. 1 of the record in the case of the Bell Telephone Company v. Dowd, comprising Bell's answers and proofs, introduced by stipulation; V. Vol. 2 of the record in the Dowd case, comprising exhibits, etc.

The taking of evidence was practically concluded in May, 1881. The case was argued before the examiner of interferences and fully submitted to him in October and November, 1881. He held the case under advisement until July 21, 1883, when he filed his decision, which covers 348 pages of closely printed matter. In cases A, B, C, E, F, I, J and L he awarded priority of invention to Bell; in cases D and No. 1 to Edison; and in case G to McDonough.

From this decision of the Examiner of Interferences Edison appealed to the Examiners-in-Chief in cases A, B, C, G, J and L. Voelker appealed in cases A and B and No. 1. Bell and Gray appealed in case G, and Irwin in case No. 1. This relieved the controversy of cases D, F and I, which remained finally disposed of by the decision of the Examiner of Interferences.

After having held the cases under advisement nearly a year, the Examiners-in-Chief, on October 23, 1884, rendered a decision affirming the decision of the Examiner of Interferences as to all of the issues except issue G, as to which they reversed him and awarded priority to Bell.

From this decision Voelker appealed to the Commissioner as to issues A and B, but Gray acquiesced therein and took no appeal; McDonough and Gray appealed as to issue G.

Pending the appeal before the commissioner, McDonough, on December 19, 1884, presented a motion

"to have the above-mentioned interference (G) re-opened in order that I may be permitted to introduce proof before the proper tribunal as to the operative character of the telephone transmitter shown in my application of April 10, 1876, involved herein, and for such other and further action in the premises as may be rendered necessary."

The grounds of the motion were that the examiners-in-chief had held that a make-and-break apparatus such as McDonough described was incapable of transmitting articulate speech; that this was at variance with the action of the primary examiner in declaring the interference, who must have found the apparatus to have been an operative one; and because, under the rules, the only method of raising the question of operativeness was by reference to the primary examiner. After full argument this motion was denied by the commissioner, on January 16, 1885.

On March 3, 1885, the commissioner filed his decision affirming the action of the examiners-in-chief as to all issues. This was a final award of priority in favor of Bell upon all the issues involved.

Nothing further appears to have been done by any of the parties in the interferences until December, 30, 1886, when there was received by the office the following petition of Gray:

"To Hon. M. V. Montgomery,
"*Commissioner of Patents:*

"Elisha Gray, one of the parties to the above stated proceedings, brings this his petition, to set aside the various orders, decisions and judgments heretofore made and rendered therein, and to reopen the same upon the following grounds, viz.:

I. "Upon the ground of newly discovered evidence, important and material in its character, and which would, as petitioner believes, have changed the various orders and judgments made and rendered in the progress of, and upon the final hearing of, said interference proceedings, if the same had been presented at the proper time to the officers of the Patent Office having them in charge and passing upon the matters and things pertaining thereto; and which evidence was not known to petitioner to exist; nor did he have any reason to suspect that it did, until long after the final decision in said interference proceedings was rendered against him, and in favor of A. G. Bell, upon nearly all the material issued therein involved; and therefore no laches can be imputed to him in not having earlier discovered and presented the same.

II. "The said newly discovered evidence will, as petitioner is informed and believes, establish the following facts, viz.: That on or about the first day of March, 1876, A. G. Bell, the successful party in said interference proceedings, went to the Patent Office, and, by undue and unlawful means and influences, procured full knowledge of the contents of, and drawings attached to, a certain caveat, accurately describing a speaking telephone, then recently (viz., on the fourteenth day of February, 1876) filed by petioner, and upon which caveat, and the invention therein set forth, and the apparatus therein described, were based the three (3) several applications for patent for a speaking telephone afterward filed by petitioner and involved in said above-mentioned interferences.

III. "By the knowledge thus obtained, in violation of law and the rights of petitioner, the said Bell was enabled to construct an apparatus, a few days afterward, by which he succeeded in transmitting articulate speech; and which apparatus, so constructed, in exact accordance with the drawings attached to, and the description and specification set out and contained in, petitioners's said caveat, he, the said Bell, subsequently claimed was the apparatus set out, described in and covered by an application which he had filed in the Patent Office on the said fourteenth day of February, 1876, purporting on its face to be an application for patent for 'An Improvement in Telegraphy,' but was never in any way claimed by the said A. G. Bell to be for a speaking telephone, nor recognized as such by any one else, until long after a patent had been issued thereon, on the seventh day of March, 1876, numbered 174,465, and which was involved in the aforesaid interference. While, in fact, no one of the devices or apparatuses set out and described in the said application never had previous thereto and never since, as petitioner is informed and believes, been made to transmit articulate speech.

IV. "It was not until after the time and the occurrences above narrated that the said Bell claimed he had invented the speaking telephone, or that he had mentioned described or claimed any such invention, or any device or apparatus constituting a part thereof, in said application filed on the aforesaid fourteenth day of February, styled an 'Improvement in Telegraphy;' and the fact is that the said Bell did not, in his said application, describe or claim any apparatus or device that could or can be made to operate as a variable-resistance telephone for the transmission of articulate speech; but by reason of having wrongfully and illegally obtained information as to the nature and contents of petitioner's aforesaid caveat, and of being thereby enabled to construct an apparatus therefore unknown to and never previously conceived of by him, that would transmit speech, and which apparatus he forthwith claimed as his own, the officers of the Patent Office were induced to adjudge him to be the first and original inventor of the speaking telephone, as against petitioner and others, because, as it was then believed, by reason of the above-recited fraudulent acts upon the part of the said Bell, he had first reduced the same to practice, though it was found and so reported by the examiner of interferences that he was not otherwise entitled to claim, or have awarded to him, priority over petitioner as to the said invention; and it was further found and so reported by said examiner of interferences, that petitioner lost whatever right he might have had secured under his said caveat to be adjudged the first and original inventor of said art of telephony as against said Bell, because of his own laches in not completing and reducing it to practice before the same was done by him, the said Bell.

V. "Petitioner further shows that by reason and in consequence of the aforesaid wrongful and fraudulent acts and doings upon the part of the said Bell, together with certain other irregular and illegal proceedings, hereafter to be set out, had and taken in the Patent Office concerning and in respect to his aforesaid caveat and the application of the said Bell, he, petitioner, was deceived and misled as to his real legal status in the Patent Office in respect to the speaking telephone, and as to his rights in relation thereto acquired by virtue of having filed his said caveat, and which rights were subsequently involved in the interferences aforesaid; and by being so deceived and misled, he failed and neglected to take such action and to obtain and present such proof in the beginning and during the progress of said interferences as he would otherwise have done, and which would, as he believes, have secured a judgment in his favor upon all the material issues involved therein, instead of being given in favor of said Bell; and among the said irregular, wrongful and illegal acts and doings, petitioner submits the following, to wit:

VI. "The aforesaid caveat of petitioner and application of said Bell being filed in the Patent Office on the same day, to wit, the fourteenth day of February, 1876, without any noting of the hour at which the respective filing occurred, the same was entitled to and should have been considered as a simultaneous act; and when said caveat and said application came for action before Z. F. Wilber, the primary examiner, to whom they were referred, he held and decided in accordance with the law and practice in that behalf, which had always theretofore prevailed in and governed the action of the Patent Office, that they were filed simultaneously, and that therefore said application should be suspended for ninety days, and that petitioner was entitled to notice of the pendency of said application, and to be also notified to complete the invention set out in his said caveat within the time prescribed by law; and the said examiner did, pursuant to law, give such notice to petitioner. But contrary to and without authority of law, he also notified said Bell of the pendency of petitioner's caveat informing him, at the same time, that it appeared to interfere with certain designated parts of his application. Upon the *ex-parte* application, however, of the said Bell, through his attorneys, Messrs. Pollok and Bailey, the aforesaid decision of the said Wilber was reversed, and it was then decided, without the taking of any competent and sufficient proof, and without notice to the petitioner, that his caveat was filed some hours later in the day than was the application of the said Bell. Whereupon, the notice given petitioner to complete his said invention was withdrawn; and soon thereafter, to wit, on the seventh day of March, 1876, a patent was issued, on the aforesaid application, to the said Bell, without models having been filed by him, as required by law, of the different devices or apparatus claimed to be set out and described therein, and without his ever having shown and demonstrated to the officers of the Patent Office, or to any one else, that the same were in any way fitted for or capable of performing the functions of a speaking telephone."

"By all of which, petitioner says the rules of the Patent Office were disregarded, the law violated, and great injustice done to him."

VII. "And petitioner further shows that said interferences should be reopened and set aside for further proceedings therein, because the same were wrongfully instituted, as aforesaid, and were not conducted in good faith, with a view to reach the real merits thereof; but were collusive and simulated in this:

"That before any proof had been taken in said interferences, or any substantial progress had been made in the same, those to whom the said Bell had previously transferred the ownership of the two patents involved, namely patents numbered 174, 465, and 186,787, acquired, or supposed they had acquired, by assignment, all the other patents and applications for patents (which were thought to possess any value) that had been put in interference with those of petitioner and of others; and among the patents and applications so acquired it was supposed by the aforesaid owners of the two above-mentioned patents of the said Bell, that the alleged interfering applications of petitioner were included; and petitioner being under *a misapprehension* in that regard, brought about by no act of his, supposed this to be true until long after the proceedings in said interferences were ended in the Patent Office.

VIII. "From the time these patents and applications were acquired, or supposed to have been acquired, as aforesaid, the interference proceedings in respect thereto, as between those representing the interest and claims of the said Bell and petitioner and certain other of the defendants, were mainly under the management and control of those who had acquired the aforesaid interest therein, and with the view of reaching such results as they desired, they paying, as petitioner is informed and believes, the counsel on both sides, as well as other necessary expenses.

IX. "And as a further and additional ground upon which petitioner submits that the various decisions made in the progress of said interferences should be set aside and the same reopened, is the following:

"That the patent of the said Bell, numbered 174,465 was adjudged by the officers of the Patent Office to be for a speaking telephone, and that it described an apparatus therefor, not upon any evidence presented to establish that fact, but because it had been so held and adjudicated in a consent decree taken and entered in a certain collusive suit, known as the 'Dowd' case, in which the same party, to wit, the American Bell Telephone Company, who had represented the interest of the said Bell in the aforesaid interferences was the complainant and one Peter A. Dowd was the nominal defendant; and in the progress of the same the parties thereto consolidated their interests, and a consent decree was entered in favor of the complainant, the American Bell Telephone Company, it paying the counsel fees on both sides of the case, together with all other costs and expenses of the same, as petitioner is informed and believes Under authority of this collusive adjudication, the officers of the Patent Office held that the aforesaid patent of the said Bell, numbered 174,465, should be put in interference with the applications of petitioner, though it was also held that said patent did not describe a speaking telephone, and that but for said adjudication it could not and would not have been put in interference as aforesaid.

X. "Petitioner asks that said interferences be reopened, upon the further ground that the officers of the Patent Office erred in putting the aforesaid patent of the said Bell in interference with the applications of petitioner as to the broad art of telephony, in this, that the said patent contains no description, specification, drawings or claim that would inform any one that it in any way relates to the art of transmitting articulate speech by any means pointed out or suggested therein; but it plainly appears upon the face thereof that it was intended alone for an improvement in telegraphy.

"And in this, that the apparatus which is described in said patent and shown in the drawings attached thereto is in no way like that set out in petitioner's application and shown in the drawings thereof, but is of entirely different construction, and operates, if it will operate at all for any purpose, upon a wholly different principle.

XI. "And petitioner further says that the officers of the Patent Office especially erred in awarding priority to said Bell in issue G of said interferences as against him, petitioner.

XII. "And, finally, petitioner moves the honorable commissioner to set aside said interferences, upon the further ground that the various orders, decisions and final judgment had and rendered therein are not supported by the evidence, nor warranted by the law applicable thereto.

XIII. "Wherefore, petitioner brings this his petition, with accompanying affidavits, proofs and exhibits, in support of the allegations therein set out and contained, and prays that the various orders, decisions and final judgment made and rendered in said interferences be set aside, and that the same by reopened, to the end that such other and further proceedings may be held in respect thereto as shall seem to the honorable commissioner to be just and lawful in that behalf.

"ELISHA GRAY.

"M. B. PHILIPP, *Attorney for Petitioner.*

"DISTRICT OF COLUMBIA,
"UNITED STATES OF AMERICA.

"Before me, A. S. Taylor, a notary public in and for said district, this day personally appeared Elisha Gray, who made oath that the statements contained in the foregoing petition are true, to the best of his knowledge, information and belief.

"Sworn to and subscribed before me this twenty-fourth day of December, A. D. 1886.

[SEAL] "A. S. TAYLOR, *Notary Public.*"

(*Endorsement.*)

"Office of Commissioner of Patents. Received December 30, 1886, petition of Elisha Gray to reopen the Telephone Interferences between himself, A. G. Bell and others.

"The petition is presented by Hon. Casey Young, with the statement that Mr. Philipp, counsel in the case, does not desire to have it acted upon until he shall hereafter present a formal motion asking therefor.

"M. V. MONTGOMERY, *Commissioner.*"

December 30, 1886.

No formal motion was subsequently presented by Gray asking for any action on the above petition, nor was any motion served by Gray upon Bell or other party of the filing thereof or that action would be asked. It was not until a general order of the commissioner was made applicable to all old cases pending in the Office to prevent delays and the prolongation of monopolies, that this petition was brought to the knowledge of the present commissioner, and under his direction it was set down for disposition on February, 1, 1888, and Bell and other parties notified.

February 18, 1887, an order was made by Commissioner Montgomery suspending action in Gray's case No. 3. Why this order was made or upon what reason, does not appear. It was made in case No. 3 as *ex-parte.*

February 23, 1887, Gray presented a proposed amendment in case No. 3, which was not entered in the case.

On April 4, 1887, Gray presented another amendment in case No. 3 which was not entered, but which is now before the commissioner as an *ex-parte* case. The amendment covers the metallic diaphragm.

March 2, 1887, McDonough filed in the interference case two petitions, as follows:

"I hereby move for an order for reopening the above-entitled interference, with leave to furnish proofs in regard to the operativeness of my teleloge as a speaking telephone; and respectfully present the following as the grounds for this motion:

I. "That the Commissioner of Patents, when the said interference was under argument on its merits, erred in receiving at the instance of the assignee of the contestant Bell, and in considering certain depositions, or what purported to be copies of certain depositions of Professors Brackett and Young, taken as a part of the evidence in the suit of the American Bell Telephone Company against the Overland Telephone Company, but forming no part of the interference record.

II. "The Commissioner of Patents erred in that he heard and decided the interference with the avowed determination, as expressed in his opinion, not to determine the issue adversely to the owners of the Bell patent; it being explicitly stated by him in such opinion that if he had become convinced that the board of examiners-in-chief were wrong in their judgment in awarding priority to Bell, he would have declined to reverse such judgment. His exact language was as follows:

"'If, on examination of the evidence in consideration of the arguments, I had become convinced that the finding and decision of the Examiners-in-Chief were erroneous, or if a serious doubt in that behalf had been raised in my mind I would have felt constrained to leave the case undecided, to be reheard by my successor.'

III. "The Commissioner of Patents erred in that instead of deciding the question of priority involved in the interference he did not either dissolve the interference (so far, at any rate, as Bell and myself were concerned), or else suspend it, and institute a special investigation as to the operative character of my 'teleloge' as a speaking telephone.

"In deciding the motion to reopen the interference, in order to permit me to adduce proof as to the operative character of my telephone, heard by the Commissioner of Patents, January 15, 1885, and refused by him in an opinion rendered on the following day, he said as follows:

"'If, on the hearing of this cause, I should ascertain that there is doubt about the operativeness of this device, and the question of priority should turn wholly on that point, and through inadvertance, mistake or surprise the evidence was not full and satisfactory, so as to enable me to reach a right conclusion without further evidence, such proceedings could be taken in that behalf as might be fit and proper to ascertain the truth. My opinion is that the case should proceed. If it occurs that further investigation shall become necessary, it is not only within the power but it would be the duty of the Commissioner to make such inquiry by means best calculated to ascertain the exact fact.'

"In view of this ground of denying the then motion to reopen it was error for the Commissioner subsequently in considering the interference on its merits to find (as it fully appears from an inspection of his opinion in the premises he did find) that the operativeness of my apparatus was a controlling factor in determining the question of priority, and at the same time not to take proper and effectual steps for the full investigation of that question, particularly in view of the fact that at the time of taking the testimony in the interference no issue was made between the parties as to the operativeness of my teleloge, neither Bell nor any other of the contestants having offered evidence to rebut the proved facts in regard to the actual transmission of speech by means of the instrument, or even theoretically in regard to its capability to transmit speech.

"The Commissioner erred specially in that, finding that the operativeness of my teleloge was vital to the determination of the question of priority, he allowed his mind to be influenced in the settlement of this fundamental question by the introduction into the case of matter taken from depositions that formed no part of the record, and as to which no opportunity was, or under the circumstances could be, afforded me to cross-examine the witnesses.

"That the depositions thus wrongfully introduced and considered had a controlling influence upon the Commissioner's decision appears from his opinion, in which he says:—

"I have considered the affidavits of Professors Young and Brackett *in connection with the evidence given by them in the case of the American Bell Telephone Company* v. *The Overland Telephone Company of New Jersey*' (being the depositions of which it is alleged that they were wrongfully introduced). 'Taking the evidence of these two scientists *as a whole*, I cannot find that they have demonstrated or that they unqualifiedly affirm the fact to be that a telephone using the make-and-break system, as contemplated by McDonough, will transmit articulate speech within the terms of the issue. It transpires in the cross-examination of those learned gentlemen' (in the depositions that form no part of the interference record, and in which I had no opportunity to cross-examine them), 'that they assume,' etc.

IV. "The Commissioner of Patents erred in that, in considering McDonough's invention of the teleloge, as described in his application of 1876, he failed to distinguish between the *actual invention* therein described and the *theory* therein presented in regard to the operation of the apparatus that constitutes the real invention.

V. "The Commissioner erred in holding that the underlying principle of my teleloge was that it should operate by a 'palpable' make-and-break system.

VI. "The Commissioner erred in not making award of priority as between me and Gray, it being upon the claim of the said Gray that the interference was based.

VII. The Commissioner erred in holding that my teleloge was inoperative to transmit speech.

VIII. "The Commissioner erred in holding (as in substance he did hold) that a telephone constructed on the make-and-break system will not talk, as is abundantly shown by the subsequent practice of the Patent Office in granting patents, special reference being made in this connection to the patent of Bonta, No. 333,816, January 5, 1886.

IX. "The Commissioner erred in awarding priority of invention to Bell, such decision being contrary to the law and the facts of the case, and contrary to sound practice.

"Wherefore, I respectfully petition the honorable the Commissioner of Patents for an order reopening the aforesaid interference, or for such other or such further relief in the premises as to your Honor may seem meet and proper, and may be just and equitable. "JAMES W. McDONOUGH.

"STATE OF NEW YORK,

"CITY AND COUNTY OF NEW YORK, ss.

"I, James W. McDonough, being duly sworn, depose and say that I am the person whose application for a patent for a teleloge (filed April 10, 1876) was involved in the interference above named; that I am advised and verily believe that an injustice has been done me by the decision in the said interference awarding priority to Mr. Bell; and that the above are good and sufficient reasons for reopening the interference.

"Subscribed and sworn to before me, this second day of March, 1887.

[SEAL] "ROBT. F. GAYLORD,
Notary Public (168), *N. Y. Co.*"

[PETITION OF ASSIGNEES.]

"Your petitioner, J. W. McDonough, a resident of the city and State of New York, and one of the parties to the above-stated interference proceedings, brings this petition, and respectfully asks that the aforesaid interference proceedings be set aside, and the various orders, decrees and judgments rendered therein be vacated and annulled upon the following grounds, viz.:

I. "Because the same were not conducted in good faith, as petitioner believes, and charges were fraudulent and collusive, and carried on with the purpose and intention of securing an award in favor of Alexander G. Bell upon all material issues therein involved.

II. "Because all of the orders, judgments and decrees taken and held in said proceedings, in so far as priority of invention as to the speaking telephone was awarded to Alexander G. Bell, were erroneous, and not supported by either the law or the facts applicable to the same.

III. "Because the proof does not show that Alexander G. Bell was the first and original inventor of the speaking telephone, or any material or necessary part thereof, but, on the contrary, the evidence shows that petitioner was himself first and original inventor as against the said Bell and the other parties to the proceedings.

"For the reasons above stated and others to be hereafter presented, petitioner prays that said interference proceedings may be reopened, and the different orders, judgments and decrees made and entered therein be vacated and annulled, and that all the issues therein involved be heard *de novo*.

"FRANK H. HURD,
"*Attorney for E. S. Stokes, and the North American Telephone Company, assignees of J. W. McDonough.*

"DISTRICT OF COLUMBIA, ss.

"Personally appeared before me, this second day of March A. D. 1887, Frank H. Hurd, who being duly sworn, says that the aforegoing petition is true, to the best of his knowledge and belief.

"FRANK H. HURD.

"Sworn and subscribed to before me,

[SEAL] "CHAS. S. BUNDY,
Notary Public, D. C."

It will be seen that the first of these motions seeks two kinds of relief: *first*, to have reopened the interferences and permit McDonough to take additional evidence as to operativeness; *second*, to have set aside the decision of Commissioner Butterworth, of March 3, 1885, on the merits, and to have a new trial granted. On March 17, 1887, this motion was submitted to Commissioner Montgomery, who, on March 29, 1887, filed a decision holding that as to the first branch of the motion he was concluded by Commissioner Butterworth's decision of January 16, 1885, which rendered the matter *res adjudicata*; but as to the second branch of the motion, the right to move to set aside the decision of Commissioner Butterworth, of March 3, 1885, on the merits of the interference, remained, unless it had been lost by laches. The decision concludes as follows:

"*First*. That McDonough has a right to be heard on the subject of vacating the award of priority made by Commissioner Butterworth, and such hearing is hereby fixed for the nineteenth day of April next, at twelve o'clock noon, at which time the petition filed on the 2nd instant by the assignee of McDonough, and which petition is not under consideration at present, will be called up for hearing.

"*Second*. I must decline to entertain that part of the present motion which is but a repetition of the one which was passed upon my predecessor."

This proceeding was conducted wholly independent of Gray's petition and proposed amendment, the former lying dormant, as before explained.

This motion of McDonough for a rehearing was not heard on April 19, but was continued from time to time until February 1, 1888. In the meantime Gray's amendment was a second time referred to the primary examiner for report. Bell was allowed to be heard, and on July 14, 1887, the examiner reported adversely to admitting the amendment. Subsequently Bell moved that the further hearing of Gray's motion to amend be postponed until after the Supreme Court should dispose of the telephone cases then pending before that tribunal. This motion was denied on November 23, 1887, and this decision advised Bell for the first time that Gray had filed a petition to reopen and set aside the interferences.

Gray's motion to amend was submitted before the Commissioner on December 1, 1887, and the argument of this motion resulted in causing the McDonough petitions and the Gray petition to be set down for disposition February 1, 1888. Gray made no request to have his petition so set down, nor did he do anything to have his petition called up for action. As previously stated, when the Commissioner ascertained that such a petition was on file, it was deemed that the public interest required that it should be disposed of without further delay. It was accordingly directed that notices issue fixing February 1, 1888, as the date of hearing. At that date parties appeared; the presentation of the McDonough petition began, and that of Gray's petition followed the conclusion of the former.

It has been deemed important to recall and set out this history of these proceedings, not only for the better understanding of the merits of questions involved, but because they characterize the conduct of the parties, to some extent, and to laches or diligence, which may affect to greater or less extent the merits.

The proposed amendment of Gray in case No. 3 has been disposed of separately as an *ex-parte* case. Reference to it here is due to its intimate relations with the matters now under consideration.

The McDonough and Gray petitions must be considered separately, but there are matters common to both which may be presented before entering upon them.

THE ISSUES.

The issues in these interferences are as follows:

A.

"The hereinbefore-described art of transmitting and reproducing at a distance, sonorous waves or vibrations of any description which consists in increasing and decreasing the strength of an electric current traversing a circuit in such a manner as to produce in said circuit a series of electrical waves or vibrations precisely corresponding in their intervals of succession and relative amplitudes to the sonorous waves, which are to be reproduced at the receiving station or stations, so that oral conversations or sounds of any description may be telegraphically transmitted."

In this interference was Gray's case No. 1, the subject-matter being that of his first claim, the Bell patent of March 7, 1876; and, among other application, those of Edison filed April 27, 1887, No. 130, Emile Berliner, filed June 4, 1877, and A. E. Dolbear, filed October 31, 1877.

B.

"The hereinbefore-described improvement in the art of transmitting vocal sounds or spoken words telegraphically, which consists in throwing upon the line, through the medium of a varying resistance, electric impulses corresponding to the vibrations of a diaphragm operated by the movements of the air produced by a spoken word."

In this interference was also Gray's case No. 1, the subject-matter being that of his second claim, the Bell patent of March 7, 1876; and, among other applications, those of Edison, filed April 27, 1877, No. 130, and Berliner, filed January 4, 1877.

C.

"*First*. The transmitter, consisting of the combination in an electric circuit of a diaphragm and a liquid or equivalent substance of high resistance, whereby the vibrations of the diaphragm cause variations in the resistance of the electric circuit, and consequently of the strength of current traversing said circuit.

"*Second*. In a telegraph-instrument operated by sound, the combination with the diaphragm of two or more electrodes placed in electrolytic liquid and operating to increase and decrease the resistance of the electric circuit by the movement derived from the diaphragm."

In this interference was Gray's case No. 2, the first part of the subjects-matter being that of his first claim, the Bell patent of

March 7, 1876; and, among other applications, that of Edison filed September 5, 1877, No. 144, the second part of this subject-matter being that of his first claim.

E.

"In an acoustic telegraph an armature-plate, the electro-magnet for the same, and a closed circuit passing from the helix of such electro-magnet to the source of undulatory electric energy."

In this interference was Gray's case No. 3, the Bell patent of March 7, 1876; and, among other applications, one of Edison filed December 18, 1877, No. 145, and that of Dolbear filed October 31, 1877.

F.

"A telephonic transmitter, consisting of a coil of wire, one or more magnets, and a disk or diaphragm, so arranged relative to each other that a motion of the diaphragm shall induce in the coil of wire an electro-motive force in virtue of the pressure of the magnet or magnets."

In this interference was Gray's case No. 1, the Bell patent of March 7, 1876; and, among other applications, that of Dolbear filed October 31, 1877.

G.

"A telephonic receiver consisting of the combination in an electric circuit of a magnet and a diaphragm supported and arranged in close proximity thereto whereby sounds thrown upon the line may be reproduced accurately as to pitch and quality."

In this interference was Gray's case No. 3, the Bell patent of March 7, 1876; and, among other applications, that of Dolbear filed October 31, 1877, one of Edison filed December 24, 1877, No. 148, and one of James W. McDonough filed April 10, 1876.

H.

"The combination in one circuit of two or more coils of wire, two or more magnets, and two or more disks or diaphragms so arranged relatively to each other that if one of the disks or diaphragms be put in motion by the voice, by a current of air or otherwise, it shall induce a transient current of electricity in its associated coil, which current shall actuate the other disks or diaphragms in virtue of the coil and magnets associated with them."

In this interference was Gray's case No. 1, the Bell patent of March 7, 1876; and, among other applications, that of Dolbear filed October 31, 1877.

J.

"The combination, with an electro-magnet of an iron or steel diaphragm, secured to a resonant case for rendering audible acoustic vibrations."

In this interference was Gray's case No. 3, Bell's patent No. 186,787 of January 30, 1877, on application filed January 15, 1877; also applications of Edison and Dolbear.

The other issues are of no importance.

After the declaration of these interferences, a motion was made by Bell to consolidate them, which motion was denied by the commissioner because the motion was made *ex parte*, the other parties not being notified. (See Bell *v.* Gray, 15 O. G., 385.)

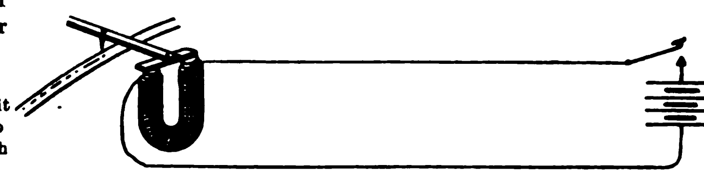
A second motion was made by Bell to reform the issues or consolidate them. This motion was resisted by both Gray and McDonough, and was denied by the commissioner on March 6, 1879. (See Bell *v.* Gray, 15 O. G., 776.) In this decision Commissioner Paine very clearly defined and construed the issues and that construction has been recognized in all subsequent decisions, both of the Office and the courts.

The Examiner of Interferences rendered a most elaborate and exhaustive decision in which he set forth the state of the art, settled what efforts had been made by the respective parties in the direction of the invention of the subjects matter of the several issues and the dates thereof; determined the facts relative to each, gave his construction to the issues, and awarded priority as hereinbefore stated. This decision, with the single exception of the construction of issue G, and consequent award to McDonough, has stood the test of all subsequent investigations, and, as a determination of the facts of the case, is, in my judgment, unassailable. No tribunal proceeding upon the evidence before the examiner of interferences would ever reach any other determination of facts.

THE STATE OF THE ART.

The decision of the Examiner of Interferences has not been officially published; I might perhaps be justified in setting forth his statement of the state of the art at the time the several parties to these interferences came into the Office, but it would doubtless take more space than would be best, and I shall therefore content myself with a brief statement.

Morse's patent for a method of telegraphy was issued in 1846 and reissued in 1848. Prior to that, various modes of telegraphing and making signs and signals by means of electricity had existed from as early a date as 1787. This had been accomplished by means of the movements of pith balls, electric sparks, etc., but the results of these methods were evanescent. The state of the art in this respect is concisely set forth in Morse's specifications. (See statement of the case in Morse *v.* O'Reilly, 15 How., 86.) But Morse invented a method by which stable or permanent signals or characters could be telegraphed. His method involved an electric circuit that could be closed and opened (make-and-break), and a piece of iron that could be magnetized and demagnetized. The ordinary Morse telegraph is well understood.



The elements required were a battery and circuits; a key to be manipulated with the hand; a piece of soft iron in the shape of a horseshoe-magnet around which passed the line-wire of the circuit, and an armature within the field of the magnet suspended on a spring. When the hand pressed upon the key and closed the circuit, the iron was magnetized and the armature was attracted to it, causing the pin to impress a dot or dash upon a scroll of paper, depending upon the length of time the circuit was closed. The click of the armature, as it came in contact with the magnet, also indicated the signals,—the dots and dashes,—and soon experienced operators became able to read the sounds of the instrument.

Here we have all the rudimentary parts from which have been evolved and developed the telephone. There are the transmitter, (the key), the electric circuit, and the receiver—the magnet and armature or plate (or disk). The transmitter operated upon the make-and-break principle, and yet it contained all the potential qualities of the modern microphone transmitter. When actually open no electric current or impulse traversed the circuit; but during the brief periods when the hand pressed the metallic electrodes constituting the keys together with greater or less force, the variable resistance of the microphone was actually executed, although without the knowledge of any one, for the secret possibility was unknown and unthought of. On the other hand, the armature suspended on the delicate spring unquestionably responded to and was capable of responding to not only the make-and-break variations, but also to the more delicate and imperceptible variations resulting from the variations of force by which the metallic electrodes of the keys were held together. If, instead of employing the hand to open and close the circuit, a toothed wheel had been adjusted so that the movement of each tooth should close and open the circuit, the armature would have faithfully responded. If the revolutions of the wheel were increased so that the circuit was opened and closed with a sufficient degree of speed, a tone would be produced at the transmitter and also at the receiver. But the tones would be those resulting from the mechanical clicking of the keys and the armature of the magnet. Still, it would also be true that the armature vibrating back and forth under the influence of the magnet would produce air-waves reproducing the tone, although they might be drowned or lost in those of the mechanical clicking of the armature.

Here we see the elements or modern discovery and invention. The transmitter was that of Reis—the make-and-break. The receiver was the magnet and the metallic diaphragm. In the Morse telegraph the armature responded to the mechanical opening and closing of the circuit; but it was potential of all that has succeeded. Was it only a new use of that armature when Reis, or Edison, or Bell, or Gray, or McDonough caused it to respond to the vibrations of tone? Was it a second new use

when Bell, or Gray, or McDonough caused it to respond, not only to pitch, but to quality—articulate speech?

The invention of the Morse telegraph stimulated investigation and invention in electricity. The idea of transmitting articulate speech took possession of inventive genius in Europe and America. Instead of making and breaking the circuit with the hand or a toothed wheel, it was proposed to introduce a mechanism so delicate that the makes and breaks could be effected by the sound-waves of the human voice. The delicate mechanism which in ancient times in the temple of Delphos was set into musical motion by the mere force of the rays of the morning sun was to be surpassed, not only in the delicacy and infinite variety of movement, but the results were to be transmitted in infinite directions and to infinite distances, and to constitute the invisible bridge between mind and mind. So that Morse has given to the world a receiver of the character described, and which possessed the capabilities that have since been discovered.

The Reis telephone had been given to the world. He introduced a transmitter constructed of electrodes which were opened and closed by the tone waves of the voice, or of a musical instrument operating on a delicate membrane called the "diaphragm." His receiver consisted of an iron rod attached to a sounding box, the rod being elongated and shortened under the influence of the rapidly-interruped electric current, as an iron rod is more slowly elongated or shortened by the effect of the heat.

As early as 1854 Bourseul had given to the world in publications suggestions as to the transmission of articulate speech, which contained descriptions of a receiver and transmitter. He said:

"The electric telegraph is based upon the following principle: An electric current passing through a metallic wire circulates through a coil around a soft piece of iron, which it converts into a magnet. The moment the current stops the piece of iron ceases to be a magnet. This magnet, which takes the name of electro-magnet, can thus in turn attract and then release a movable plate, which by its to-and-fro movement produces the conventional signals employed in telegraphy."

Then, after adding the mode in which speech is transmitted by the vibrations of the air, he continues:

"Suppose that a man speaks near a movable disk sufficiently flexible to lose none of the vibrations of the voice, that this disk alternately makes and breaks the connection with a battery; you may have at a distance another disk which will simultaneously execute the same vibrations."

In "The Wonders of Electricity," a publication translated from the French of J. Baile, published in 1872, there is found a further description of a receiver and transmitter. After adverting to the marvels accomplished in the transmission of thought, handwritings and drawings, and referring to the acoustic telegraph as disclosing a new principle or discovery, he says: "Already experiments have been made for this purpose," and he proceeds to describe an apparatus resembling that of Bourseul, with the addition of an electro-magnet for giving motion to the plate in the receiver. The transmitter contains a plate, which, at each vibration, touches a small point placed in front of it, and so throws an impulse of electricity on the line which shall cause the attraction of the second plate whose size and quality are identical with the former, causing it to perform the same number of vibrations per second and give forth a sound "which will have the same musical value as the first. If this be perfected a series of sounds, a tune, a spoken sentence and conversation" may be transmitted, but as yet it has not been accomplished.

Here is a complete description of a make-and-break telephone having a receiver consisting of an electro-magnet operating upon a metallic disk placed before it. There is no occasion here to consider or dwell upon the multiple or harmonic telegraphs invented by the various parties to these interferences. They all proceeded upon the make-and-break principle to be hereinafter considered. But the important fact to be noted is that at the date these several inventors entered upon the field of invention in respect of the transmission of speech, the electric circuit was old; the Reis transmitter was old; the metallic disk or armature attracted by a magnet was old. As to the receiver, unless there were invention in applying it to harmonic telegraphy over the Morse use of it in his telegraph, or in applying it to the reception of quality over and above both, then neither Bell, Gray, McDonough nor any one else could secure a patent for it broadly. It was as old as, if not older than, the Morse telegraph.

At the time these parties to the interference came into the Office it was old to produce variation in the strength or volume of the electric current by means of the variable resistance, whether effected upon the principle of the microphone or the liquid of high resistance. It is also proper to say that the telephone does not depend upon a diaphragm receiver, and that with a proper transmitter speech can be transmitted wholly without a diaphragm as an element in the receiver.

Thus when properly understood it will be seen that the telephone when invented consisted of elements which were all old, and that the invention consists in an adjustment and arrangement between these old parts by means of which a result never before reached was attained. It must also follow that not any of these old elements could be broadly claimed, but must necessarily be limited to their proper place and situation in that new arrangement and combination, and to their specific construction.

As the present petitions seek to have all the orders and decisions set aside, new evidence taken, and a rehearing upon the merits, it is necessary to a proper understanding that so much of the material portions of the decisions as relates to the claims of Bell, Gray, and McDonough be set out.

As to Bell, the Examiner of Interferences gave him as the date of his invention the date of the filing of his application. It was urged before him that Bell's application and patent No. 174,465 did not show the invention, and that he in fact had never conceived the invention of the telephone nor reduced it to practice until after his patent issued; but the Examiner of Interferences, while evidently inclining to this view, felt concluded by the decisions of Commissioner Paine and of the courts. He says:

"Upon the evidence presented it must be held that the subject-matter of this interference .... had not been invented, that is, demonstrated, by any of the parties to this interference prior to the filing of Bell's application, February 14, 1876; nor is it entirely clear that he had at that time any knowledge of a practical mode or mechanism for producing the results contemplated by the invention. But as the Office as well as the courts have determined that the patent contains a sufficient disclosure of the subject-matter in dispute, it must be held that the invention was made at least as early as the date on which he filed his application.

"Bell's claim does not, however, depend upon the application alone, for he was in fact and in law the first to disclose and publicly explain the principle, as well as the first to construct and use instruments not only designed and adapted to carry into effect that principle, but actually and successfully used for that purpose."

As to issue C, which covers the liquid transmitter, he says:

"While no such instruments are found described in Bell's patent, his proof as to 'Exhibit 41,' its description, use, and exhibition, are considered as amply sufficient to defeat the claims of Gray and Edison founded upon the facts appearing in the record, at the same time anticipating Richmond's record date of August 24, 1877."

As to Gray the examiner finds:

". . . He claims, however, that at this time (1867) he conceived the idea of constructing an instrument for transmitting tones 'similar in its general aspects to the instruments made at a later date.' As the character of these mental speculations cannot at this day be determined, and as they took no material form or expression until seven years later, they can no more be considered as affecting inventions subsequently developed, than can Bourseul's prophecy regarding the transmission of speech by electricity. He does not appear to have considered the matter further until the latter part of January or first part of February, 1874, when his attention was again accidentally called to the subject by what is known as the 'bath-tub experiment.' His nephew was engaged in taking shocks from an induction coil by connecting one end of the secondary coil to the zinc lining of a bath-tub and holding the other end in one hand Upon rubbing the zinc lining with the free hand to complete the circuit, Gray noticed that a sound proceeded from under the hand at the point of contact apparently of the same pitch and quality as that of the electrotome of the induction coil. His curiosity was aroused, and he at once tried the experiment himself, and was astonished to find that by rubbing hard and rapidly he could amplify the sound, and that by changing the rate of vibration of the electrotome a corresponding change was effected in the pitch of the sound under his hand. (Int. III, 387; Dowd, I, 123.)

"He says of this experiment that his attention was particularly attracted to the fact that 'the quality as well as pitch and loudness could be transmitted electrically through a telegraphic circuit and received upon a common or universal receiver (Dowd I, 123). Experiments were continued during February and March, using the same induction-coils and various receivers, among which was the exhibit Animal Tissue Violin Receiver, wherein a plate of metal is substituted for the strings, and by rubbing the hand across this plate the sounds of the electrotome were produced. It was during this period, according to Gray, that he conceived the idea of transmitting musical compositions and sounds of all kinds, including articulate speech (Int. III, 388); but, as would appear from

the record, his energies were directed exclusively to the transmission of musical tones and their utilization for telegraphic and other purposes, no attention being given to instruments for the *reception*, transmission and *reproduction* of articulate speech until along in February, 1876, and, although he claims to have had some conception of the *possibilities* late in the fall of 1875 (Int. III, 391; Dowd I, 125), he neither disclosed them to others nor clothed them in any fixed and positive form until he made the sketch for his caveat, February 11, 1876. Whatever may have been the inherent capacities of the instruments constructed in the interim, they were not designed for nor known to be capable of the transmission and reproduction of articulate speech (Dowd I, 389, 98-99; Int. III, 375-389), nor were his transmitters either intended or adapted for the reception of sounds, but were designed to create and originate the particular sounds to be conveyed. Both Gray and Goodridge were led to *believe* that the receivers used in the winter of 1874-5 were adapted to reproduce the sounds of the human voice, (Dowd I, 99-107-108-124), if they could be impressed upon and transmitted by the electric current, but they were totally unaware of any transmitter capable of performing this highly important and essential task, and it was not until Gray had witnessed the successful operation of Bell's telephone at the Centennial that possibility of using his receiver as a transmitter was suggested to his mind, as Gray frankly admits (Dowd I, 399). His idea of a transmitter—and it was merely an abstract idea, such as cannot under the law be regarded as a conception—is thus stated by him (Int. III, p. 388): 'During these experiments I observed that the quality of the sound made by the transmitter was faithfully reproduced in the receiver. This led me to the conclusion that it was only a question how to convert the aerial vibrations made by the production of any sound whatever into electrical vibrations of a similar character with respect to rate, amplitude, etc., to solve the problem of transmitting articulate speech. I was *convinced* that the receiver would reproduce articulate words inasmuch as it *seemed* to be capable of reproducing any form of vibration that I was *able* to transmit. I remember speaking of this to different ones about this time. I may have mentioned this before the first of April (1874), or it may have been a little while after. My impression is that I first mentioned it before. My conception then of an instrument for transmitting articulate speech was one of a complicated character, having a series of transmitting-points adapted to respond to all the tones of the human voice, somewhat similar to the apparatus referred to in my caveat of February 14th, 1876.' The description contained in said caveat is as follows:

"I contemplate, however, the use of a series of diaphragms in a common vocalizing-chamber, each diaphragm carrying an independent rod, and responding to a vibration of different rapidity and intensity, in which case contact-points mounted on other diaphragms may be employed."

"When called upon to explain the construction of the apparatus thus ambiguously outlined, Gray confesses that it was but a general idea not clearly defined in all its details, and was based upon a theory which has since proved to be false. (Dowd I, 135.) The instrument was never constructed by him.

"Thus, by tracing this original idea of a transmitter from its conception in 1874 to its mere mention in the caveat of 1876, we find that it amounts to nothing but an abstract speculation. Passing now to the form of transmitter described and illustrated in said caveat, and the application of October 29, 1877, we will endeavor to trace back its origin, premising, however, that Gray alone testifies as to these mental operations, for Goodridge, his assistant in all experiments during this period, when asked if Gray had ever described any instrument which he had devised for transmitting speech electrically by talking to the transmitter prior to the caveat, says (Int. III, 371:) 'I heard no description from Mr. Gray of any instrument which he had devised fully, but merely some idea or plan by which it could or might be done'; and his first definite knowledge of the transmitter illustrated in the said caveat was February 11, 1876, when the exhibit 'Speaking Telephone Caveat, original sketch,' was handed him for the purpose of having drawings made for a caveat. (Int. III, 336, 394.)

" . . . Gray seems to have been indebted to the so-called lovers' telegraph for suggestions as to the construction of an instrument for transmitting speech electrically. 'The observation in respect to the lovers' telegraph proved to my mind that the movements of a single point on the diaphragm corresponded accurately with the movements of the air produced by any spoken word or sound;' (Int. III, 397;) and it was after this observation in November or December, 1875 (Dowd I, 122), that he seems to have abandoned his preconceived ideas of multiple diaphragms (undoubtedly intended as analyzers, each diaphragm being tuned to and adapted for the transmission of a given note corresponding to its fundamental or normal rate of vibration), and to have fixed upon a single diaphragm as theoretically adapted for the reception of sound-waves and their conversion into corresponding electrical impulses. Gray thus describes the results of his observations on the 'lovers' telegraph' (Dowd I, 125); 'I saw that if I could reproduce electrically the same motions that were made mechanically at the centre of the diaphragm by speaking upon it, such electrical vibrations would be reproduced upon a common receiver in the same manner that musical tones were; and from the fact that the electrical vibrations were the same in respect to rate, amplitude and form or complexity, as the motions made in the air by uttering words or sounds, it followed that the receiving-diaphragm would be thrown into mechanical vibration or motion of a corresponding character, and consequently reproduce the same word or sound. The fact that the longitudinal movement (in water or other fluid of poor conducting quality) of a wire or some good conductor of electricity, with reference to another wire or metal conductor, produced variations in the resistance of an electric circuit proportional to the amplitude of movement, was old in the art of that time; so that the last link of knowledge necessary to solve the problem in my mind was furnished in the capabilities at the longitudinal vibrations of the string in the before-mentioned so-called lovers' telegraph.' But this knowledge does not seem to have been disclosed to others, nor to have been reduced to form until February 11, 1876, when the sketch for the caveat was made.

"The answer above quoted most satisfactorily confirms the conclusions reached regarding the incompleteness of his pre-conceived multiple diaphragm idea, for in it he acknowledges there was a defect or missing link, even in his theoretical transmitter, which was remedied or supplied by the 'lovers' telegraph' and the knowledge derived from observations made as to its operation. February 11, 1876, is, therefore, the earliest date that can be accorded Gray for the conception of his first instrument organized designedly for the transmission of articulate speech. . . .

" . . . He had already made and patented instruments capable of responding to varying impulses of electricity, but, instead of relying upon these for receivers, he contrived a new form of receiver, retaining only that part which was well known, long before his discovery, to be capable of responding to fluctuations in the current—*i.e*, an electro-magnet and armature, and to this applied the membrane diaphragm and vocalizing chamber of the lovers' telegraph.

"These circumstances lead to the conclusion, as before stated, that the invention of the art of transmitting and *reproducing* articulate speech, and the means therefor, was not contemporaneous with nor the natural outgrowth of the transmission and production of musical tones, as previously practiced by him; but it is to be regarded, under the law and upon the evidence adduced, as anterior to and derived from the lovers' telegraph, so called. . . .

" . . . It was during these experiments that he claims to have observed that the *quality* of the sound made by the transmitter was faithfully reproduced in the receiver, from which he drew the conclusion 'that it was only a question how to convert the aerial vibrations made by the production of any sound whatever into electrical vibrations of a similar character, with respect to rate, amplitude, etc., to solve the problem of transmitting speech' (Int. III, 388). He says, moreover, that he was 'convinced that the receiver would reproduce articulate words, inasmuch as it seemed to be capable of reproducing any *form* of vibration that I was able to *transmit*.'

"In the early history of the art the *possibility* of transmitting and reproducing speech by *imaginary* devices did not lack advocates, several of whom, prior to these alleged mental speculations of Gray, had approached much nearer in their prophecies and predictions than he ever claims to. The various descriptions of the Reis telephone evince a recognized capacity in the receiver to respond to such tones as were thrown upon the line by the transmitter; and various scientists have said it were possible *if* the means could be devised. Gray was, therefore, no nearer the solution of the problem when he recognized that the question was *how* to convert sound into electrical vibrations of a similar character than many who had preceded him. . . .

" . . . The history of his experiments, from the bath-tub experiment, in January or February, 1874, to the caveat sketch in February 1876, as narrated above, establishes beyond peradventure the character of the inventions upon which he was engaged, viz.; the electrical production of music and the multiple transmission of telegraphic messages. He neither sought nor contemplated the *transmission* and *reproduction* of sound as such; not a single transmitter was designed or adapted for converting sound-waves into corresponding electrical impulses; on the contrary, every tone or sound heard at the receiver, instead of being a reproduction, was a new creation, the product of a certain series of undulations induced in the current by the transmitter, and made manifest for the first time at the receiver. Tones accompanied the action of the transmitter while establishing these series of electrical vibrations or undulations, but they were merely incidental. He was aware of Reis's experiments, but evinced no disposition to follow in the same direction. He proceeded to develop a system of telegraphy wherein two or more transmitters were employed, each capable of setting up an arbitrary series of electrical impulses or vibrations in the line; the receivers at first were designed to respond to the tones resulting from these vibrations. (Dowd I, 100-1.) The knowledge possessed by him at that time led to the use of an electro-magnet for this purpose, for the researches of Page, Henry, and others, and his experiment in 1867, demonstrated the capacity of such an instrument to respond to electrical vibrations or impulses, and he himself acknowledges having observed this property in 1874, and that the armature or diaphragm, so called, was unnecessary (Int. III, 390); the duration of the vibrations of each transmitter was to be divided into longer and shorter periods representing the dot and dash of the Morse alphabet, and the sound of each, as produced by the receiver, was to be noted separately; (Dowd I, 99-100;) the resonant box, the wash-basin, and the tin cup were in all probability designed and used for the sole purpose of simplifying the sounds. At least there is no evidence to the contrary. In his first patent embodying the resonant-box magnet-receiver No. 166,095—he says, speaking of the secondary circuit: 'As the receiving electro-magnet is connected with the circuit it will be caused to vibrate, thus producing a tone of corresponding pitch, *the sound of which may be intensified* by the use of a hollow cylinder S of metal placed on the poles of the magnet. The 'diaphragm-box-magnet receiver' was regarded as a modification of the 'resonant-box magnet-receiver,' and was not made as a new form of receiver, but for use in testing the feasibility of transmitting tones over a long line. It was necessary that a receiver of some kind should be employed, and inasmuch as, at the time of said trial, 9th of Feb., 1875, one of the two resonant box magnet-receivers had been filed as a model in the Office and the other sent to New York, where it remained (Dowd I, 84-95), he had this diaphragm-box magnet-receiver made as substantially the same thing. The 'concave metallic diaphragm magnet-receiver' may therefore be regarded as the last of its type. Passing from this style of receiver, wherein two or more tones were produced, and, when employed telegraphically, required that the operater should disregard all but the one which he was to answer for (Dowd 4, 329), he devised a means for deadening all tones except the particular one corresponding to a given transmitter, and to this end he employed separate receivers, with sounding-boxes as analyzers, and this he also adopted for his musical receivers. The next

step forward was to provide the analyzing receivers with means for operating a local circuit, in which was included a Morse or other telegraphic receiver, when, and only when, the corresponding transmitter was in use.

"That this line of invention would ever have eventuated in the modern articulating-telephone no one can predict. The capacity of his receivers to respond to electrical undulations induced by a proper transmitter under the influence of sound-waves of any description, whether articulate, as in the modern telephone, or musical, as in the Reis telephone, was not capable of demonstration under the conditions in which they were used; it was a purely latent property, and would never have been discovered had the articulating transmitter not been invented. He does not appear to have even contemplated their use with a Reis transmitter or any other of its kind; hence his inventions were not engrafted upon the former as improvements.

"His mental speculations or anticipations of future possibilities for his instruments cannot be classed as inventions, nor even as conceptions of inventions, for they were neither reduced to definite form and proportions, nor experimented upon with a view to their development.

"The several receivers described were not designed or used for the *reproduction* of articulate speech or other sounds, but it is claimed that some of them, at least, possessed the inherent capacity of rendering audible sound-impressed currents; that this function was inseparable from the structure and was sufficiently demonstrated by the use made of the instruments. The devices mainly relied upon are the 'resonant box, concave metallic diaphragm, and diaphragm box magnet receiver.' These were used in 1874 and 1875 for rendering simple and complex tones, as produced by the musical transmitters heretofore described, and when so used included in a closed circuit.

"While it is satisfactorily established that they did perform the functions of musical receivers and operated satisfactorily to render audible certain electrical waves or undulations created by the transmitting-instruments, it is equally certain that such use was occasionally and experimentally only, and their use was ultimately abandoned and their place supplied by instruments of a different design.

"Aside from the fact that after a few trials they were laid aside and never utilized or applied in the same or modified form, it is extremely doubtful if the so-called diaphragms were intended to be responsive to the varying attractive force of the magnets, as from the testimony inferences alone can be drawn as to their actual operation. As one of the latter applicants, all doubts on this score must be resolved against Gray.

"The blacking box, the wash-basin, and tin cup were none of them employed primarily for producing the sound; that function was performed by the electro-magnet itself, as appears from the testimony and patent No. 166,095. Their purpose seems to have been the same as the resonant case and cover of the Reis receiver, *i. e.*, to increase the volume of the sound proceeding from the magnet. It is nowhere stated in evidence that any other purpose was had in view; hence it is fair to presume that if the diaphragms did, in fact, respond to the electrical variations, it was an unforeseen and unnoticed circumstance. And again, the magnet being, under the conditions of use, the source of sound, there was no necessity or opportunity for discriminating between the sounds which might have emanated from the diaphragm and those known to proceed from the core; hence the capacity of a diaphragm to respond to sound waves electrically transmitted could not and was not ascertained or taken advantage of.

"None of the witnesses refer to any observations made as to the capacity of the diaphragm to vibrate and thereby produce sound, irrespective of the audible effects produced by the magnets. There is every reason to believe that the cases were intended to act as reflectors or resonators, and that, in so far as the other functions of a vibrating diaphragm sensitive to sound-impressed currents was concerned, it was unknown, unappreciated, and would not have been mentioned as pertaining to the structure or use of these instruments were it not for the invention of the articulating-telephone, the introduction of which was the signal for the presentation of claims based upon devices which, so far at least as the sensitiveness of the diaphragm was concerned, had never been tested, the use of which in the system proposed had been discontinued, and the instruments virtually abandoned. . . .

". . . The system favored by Gray, and to which his attention seemed the most devoted, did not require or demand the sensitive diaphragm. Aside from what are termed the animal tissue receivers, we find him experimenting with universal receivers for a time, and ultimately putting them aside for individual responsive receivers. The first and third he embodied, in a variety of forms in patents, but the second found no place in these patents, except the resonant box receiver, which, as has been shown, was not alleged or claimed as containing a diaphragm.

"When he came to file his caveat, instead of nominating one of his old instruments for receiver he devised a new one, including a diaphragm stretched across a chamber, and carrying a piece of soft iron to act as an armature. This diaphragm becomes, in his application, a thin sheet of steel or iron, rigidly supported at its edges. Clearly, the use of these old instruments, in the manner, and for the purpose described in the application, was an afterthought, incident upon the introduction of the articulating telephone.

"Until then there was no suggestion as to their action, nor was the use to which they were put such as to develop or prove their capacity. As matters of evidence they furnished no fund of information from which the public or their projectors could derive any benefit. The so-called diaphragms were not regarded as the sound-producing medium; that was the accredited function of the magnet; but the devices of which they formed material portions were added to reinforce or deflect the tones, like a sounding-board and a sound-board respectively."

As to McDonough the examiner finds:

". . . This brings us down to the period when he claims to have first disclosed the invention to others. It will be well to consider the nature of the testimony we have been discussing, and its bearing upon the invention.

"In the first place, there is not the slightest proof as to the nature, structure or mode of operation of any instrument devised by him for the purpose of transmitting and reproducing articulate speech; nor does he even seem to have had a definite idea of such an instrument. There are but three circumstances that can be adduced in his favor: the experiment of 1867: the sketch of 1871, with its legend 'to send speech through wires by means of electricity,' and his conversation with Eastman in the spring of 1874, wherein he expressed his opinion that it might be possible to send speech over a wire, at the same time referring to the sketch of 1871 as being designed for that purpose. The question at once arises, does this constitute satisfactory proof of the conception of an instrument adapted for the transmission and reproduction of speech, or for any other purpose? The experiment of 1867 must be disregarded not only as uncorroborated and unwitnessed but as clearly abandoned. The sketch of 1871, as previously remarked, was made solely as a memoradum for recalling to mind fugitive ideas. Except for its legend, there is nothing to indicate in the slightest the purpose of the device represented; and the manner in which that object was to be attained is neither expressed in the illustration described to others, nor, so far as the evidence shows, was it understood or even devised by McDonough himself. . . .

"Apparently spurred on by the discussion with Eastman (1875) he entered upon what may be regarded as the first stage in the process of invention. He does not appear to have had such a knowledge of and familiarity with the art as it then existed as would enable him to judge of the correctness of his theory with any degree of certainty; he speculated upon possibilities, and was groping in the dark for the means of realizing his expectations.

"Let us assume that he had in contemplation an instrument for transmitting and reproducing articulate speech, wherein was to be embodied a diaphragm to receive the sound waves and another to reproduce them, with *some means*, unknown and unexplained, whereby the vibrations of one diaphragm were to set up corresponding vibrations in the other through the medium of electricity. If this constituted an invention, it was clearly anticipated by Du Moncel's description of a combination in every way as complete as any disclosed by McDonough up to this time. 'Imagine that you speak against a sensitive plate so flexible as to lose none of the vibrations produced by the voice, and that this plate makes and breaks successively the communication with the electric pile; you may have at any distance another plate, which will undergo in the same time the same vibrations.' (Prescott, 147.)

"But it is argued, McDonough had made and tested his receiver in 1867, and made drawings of a transmitter and receiver in 1871, and subsequently in 1875 made an instrument, whereas Bourseul never did. To this it is answered that the 1867 experiment, whatever it was, amounts to nothing, having been entirely and completely abandoned; while the 1871 sketch, standing, as it does, alone and unexplained, proves nothing whatever. A speaking telephone made according to Du Moncel's description has never, so far as we are advised, been successfully operated, and there are defects and omissions which, in the present advanced state of the art, make it apparent that it could not be made to work. But what can be said of McDonough's devices? He has made no record of his ideas, hence we cannot say they were either good or bad, for the simple reason that we do not know what they were. As to the receiver alleged to have been made in 1867, there is nothing to indicate its capacity even to receive and reproduce the impression made upon the current by a proper transmitter, had one existed; but, inasmuch as the transmission of articulate sounds by means of electricity had not been, to his knowledge, accomplished, the capacity of the receiver to respond thereto could not have been determined by him had the said receiver been in his possession and in daily use with the mechanical transmitter. This, then, was the status of McDonough's inventions when, in the latter part of May, 1875, he began the construction of his first instruments designed for the transmission and reproduction of articulate speech by means of electricity. (488.)

". . . As to the results produced, McDonough says: 'We could hear with this instrument perfect tunes and could distinguish the tone of the voice, but I do not remember of hearing any distinct words.' (492.) Whereas Eastman, who assisted, says: 'The results from these experiments, as heard at the other end, or in the receiver, was a variation of rattling sound and musical tones; (510;) and again: 'We made many experiments with this machine, and at times we could distinguish the tune that was sung. (*Ibid.*)

"Without apparently understanding the cause of his failure, or at least without any express purpose to depart from the general principles embodied in these first instruments, he constructed a new transmitter and receiver (493, 4, 5.) which he tested at a date not later than the 30 of June, 1875. (496.) Although McDonough fails to state the purpose of any changes effected in these new instruments, Eastman says he thought the diaphragms were too small (510), and that the needle was abandoned, because he could find no way to keep it from jumping; (511;) whereas, it would appear from his previous answers (q. 15, p. 510) that McDonough sought to facilitate the movement of the needle by putting in the glass tube; and the new transmitter, as at first constructed, did not provide a means for maintaining contact, but the necessity for some device for preventing the displacement of the contact-piece was suggested by the use of the instrument. (495.) The instrument made at this time is illustrated in McDonough Drawing No. 4, Transmitter Exhibit No. 3, and Receiver Exhibit No. 4, and is substantially identical in principle and mode of operation with that upon which the present application was based. (502.)

"He took the iron hoop, twelve inches in diameter (499), used in his 1867 experiment and had a duplicate made. Upon each of these hoops he fastened

parchment diaphragms, by first winding cotton cloth around the hoops, and then pasting the parchment to it. Near the centre of one of the diaphragms is pasted a piece of tinned iron, and mounted the hoop upon a base in front of the electro-magnet used in his previous experiment. This constituted the receiver.

"The other hoop he used in the transmitter. Near the centre of the diaphragm two pieces of thin German silver were pasted, about an inch and a half apart (499), with a wire attached to each. A bridge or arch-shaped piece of this German silver rested loosely upon the pieces of German silver on the diaphragm; the circuit was from one of the pieces, through the bridge to the other piece, thence through the coil of the receiver back to the battery.

"When these devices were first tested it was found that the bridge piece was shaken off from the contact pieces by the vibrations of the diaphragm; and to remedy this he sought to maintain the bridge piece in place by passing a thread through it and the diaphragm, tying a knot above the former, and one below the latter. He mentioned incidentally that they 'twisted the thread to tighten it' (495), referring to the bridge piece. With these instruments, McDonough says, 'we could distinguish tunes and some words distinctly.' (495.) He then substituted for the thread a screw-threaded pin, fastening it to the diaphragm by two nuts, one above and the other below, and placed another nut above the bridge piece.

"This constitutes the perfection of his invention, and it only remains to consider the nature of the results obtained therewith. . . .

". . . The results obtained are testified to as follows by McDonough: 'We obtained results as follows, viz., clearly-recognizable tunes and entire sentences of clearly understood words were transmitted through the instruments and heard at the receiver;' (496;) and when asked to specify the tunes or spoken words, he says: 'To my knowledge, the tunes were "Swanee River," "Muffin Man," "Shoo Fly," and some others. The words which impressed themselves upon me more particularly were, "Way Down Upon the Swanee Ribber, far, far away," which I heard consecutively and clearly, noticing the elision at the beginning of the word "way," and the change of "v" to "b" in the word "river." The words of other tunes were distinct when the instruments were properly regulated. I myself could distinguish peculiarities of voice in those speaking or singing. (497).

EASTMAN:

"I assisted Mr. McDonough in operating the machine whenever I had time, and we were home together generally every evening, and I guess we exhausted all the songs we ever heard. I can give you the names of a few of them; others I do not remember. They were 'Swanee River,' 'Down in a Coal Mine,' 'Old Zip Coon,' and others that I have forgotten. I heard many of the words of these songs; exactly which words I can't remember. I also heard Mr. McDonough say 'Halloo, Frank,' and other words that I can't remember now." (512.)

WILSEY, McDonough's stepfather:

"It was in the latter part of June, the exact date I can't recollect, 1875, at 72 Warren Avenue, Chicago, I asked Mr. McDonough what results he was getting. He told me he was pretty well satisfied. I requested him to let me listen, in order to hear whether I could hear anything or not. I listened at it. At first I heard nothing. I concluded that I was a little too far from the machine. By getting very close to it I could hear singing; I was able to determine what tune he was singing. I also was enabled to catch now and then a word; that is all." (522.)

J. E. McDonough, applicant's brother:

"It was at 72 Warren Avenue, in the latter part of June or near the first of July, 1875. I was called to listen by my brother one evening while my mother was singing in the parlor of the house, and I heard the singing; and, slapping my brother on the back, and saying, 'By George, Jimmie! you've got it after all' (524), I heard "Down Come Uncle and Aunt, Down Come Sister Caturah." That's about all I can recollect at the time of hearing.' (525.) The words referred to above were the words of a song he had often heard his mother sing. (526.)

The above are the only parties who testify of their own knowledge as to the working of the device. In addition to this, however, there is the evidence of three parties: Jeffery (527), Cobb (529), and Wilkins (532), to the effect that in 1875 McDonough incidentally stated to them he had an instrument with which he could send speech through wires, by means of electricity. . . .

"With respect to the construction and mode of operation of the several devices before referred to, evidence of two kinds is presented, and from this and the surrounding circumstances we are called upon to determine, as best we may, the nature and extent of McDonough's invention; for with the filing of his application his work as an inventor in this line came to a standstill.

"The two kinds of evidence referred to are the testimony of witnesses as to transactions occurring a number of years previous, and the description of the apparatus as contained in the application. With respect to the first of these it would seem, upon a careful examination thereof, to be insufficient to establish beyond doubt or question the successful reduction to practice of an articulating telephone, whatever else it may prove. Not a single witness describes, nor does it appear that he was conversant with, the conditions necessary to render the instruments capable of transmitting and reproducing articulate speech. It is not pretended that, prior to the last of June, 1875, any instrument had reproduced a single articulate sound; and this was due, it would seem, to the fact that the transmitter broke the circuit instead of maintaining a constant control over it. Without designing, so far as the record shows, to depart from the principles underlying previous constructions, he made an instrument such as is embodied in his application, obviously capable of operating in the same manner as those that preceded it, and with it obtained the results stated. Conversation was not carried on with it, but tunes were recognized, together with some words of the tune. A sound approximating to a familiar tune naturally suggests to the mind the words; it is frequently a mental deception, as observation teaches. That his experiments amounted to more than this, has not been satisfactorily proved. He may have advanced a little beyond Reis, but it is not certain.

"Not having fully realized his expectations, he attempted to improve not alone the loudness, as he would have us understand, but the distinctness also (518;) in this he failed. Fearful lest others should outstrip him in the accomplishment of that for which he was seeking, but had not found, he concluded to file an application for a patent.

"This application, then, must be presumed to contain the best explanation of his invention that he could furnish to the public; it forms the standard with which his invention must be compared and measured. Further progress was abandoned, the instruments neglected or destroyed, and, except as described in said application, not a single person, including himself, knew how to construct and operate the devices for the accomplishment of the end in view. Even if accidentally and without knowing how to repeat the operation he had used the devices in such a manner as to produce the result aimed at, he had not made the invention, for he could not repeat the effects. He is not entitled to a patent for possible combinations, but for such only as he has devised and can and does instruct the public in the use of. The mere allegation that a described combination will produce a certain result when in fact it will not, does not render him entitled to exclude others from using the same elements in a different relation for producing that result. Such changes amount to independent inventions. What others may succeed in doing with the instrumentalities he had constructed by establi hing a relation of the parts unknown to him does not inure to his benefit nor entitle him to claim such invention as his own.

"The application, which we will now consider, was filed by an attorney who undoubtedly received information for the preparation of the drawings and specifications directly or indirectly from McDonough himself. He is not produced, however; hence the application, stands alone as representing what he had accomplished, and it cannot be departed from; and, if it could, there is certainly nothing in the testimony to warrant the conclusion that, without apparent reason or purpose, he, either ignorantly or designedly, described his invention other than as he knew it. The instrument is denominated a teleloge, and, as we find no evidence of its having been so termed before, it is fair to presume that the word was coined at the time and for the purpose of the application. . . .

". . . Then follows a description of the apparatus made the last of June, 1875, the bridge-piece being referred to as the *circuit-breaker*, and is thus described: 'D is the circuit-breaker, which consists of an arch-shaped piece of metal *loosely* secured at its centre upon the bolt D, and is bent upward at e ch end, and from the membrane A, as shown in fig 3, so as to form independent V-shaped points adapted to rest upon the respective plates C C. The circuit breaker D is so fitted upon the bolt D as to admit of a free and easy ascending and descending movement, *the limit of its ascending movement being determined by its contact with the nut E on the bolt, and the descending movement being limited by its contact with the plates C C*'. . . .

". . . There cannot be the shadow of a doubt but that he claimed to have invented an instrument which should operate to transmit articulate speech by opening and closing, or, as he says, 'breaking and closing,' an electric circuit. It is the judgment of all the experts examined in this case, as well as of the Office, that articulate speech cannot be transmitted by such an instrument. Had a patent been granted upon this application as it stands it would undoubtedly be void as for an inoperative device.

"As opposed to this proposition, what do we find tending to establish the contrary? Only the testimony of three or four witnesses that they recognized the words of some familiar tunes, and the allegation contained in the application that a device constructed as described will transmit and reproduce articulate speech. This, it is submitted, is not sufficient proof of the fact; the only inference that can be drawn from the record is that the witnesses are either mistaken, or he operated the device in a manner different from that set forth in his application, and unknown to him.

"But these are not the only circumstances from which such a conclusion can be drawn. He describes in his application an alternative form of transmitter, which must be presumed to operate upon the same principle and with the same results as the one illustrated. *It is the instrument made in May*, 1875, with which they could 'recognize tunes *but no words*,' and is thus described: 'I do not limit myself to the construction and arrangement of the circuit-breaker D,' as shown and described, 'as other means may be employed, as for example, only one of the plates C may be attached to the membrane and the other made either in the form of a plate or *needle* and attached directly to the connecting wire, and adjusted to rest upon the plate *so as to break the connection by the vibration of the membrane, which will accomplish the same result*. . . .'

". . . There is but one more circumstance to be noted, and the history of McDonough's invention will be completed. Interferences A to L were declared March 26, 1878, at which time the applications were open to inspection by the several contestants. McDonough was included in G alone, but from the complex nature of the several cases they were treated substantially as one case, and he undoubtedly knew of the other issues involved, and knowledge is brought home to him in the matter of the decision of the commissioner, published in the *Official Gazette* of May 13, 1879, he being a party thereto. In a communication addressed to the Office and filed August 23, 1879, he makes the following inquiry: 'Having fully described in my application filed April 10, 1876, a *speaking* telephone, am I not properly concerned in the case of Interference A?' to which the Examiner of interferences replied, under date of August 28, 'that the judgment of the Office was that he could not be a party to case A. If he thinks that judgment wrong, his proper remedy is to move (by regular motion) to be made a party thereto.'

"Had the Office regarded McDonough's mode of operation as the same as that of the contestants in case A, his application would have been included therein: but as it purported upon its face to be for a different method, and the Office not

being in a position at that time, for want of sufficient information on the subject, as yet in its infancy, it was not rejected as inoperative for the transmission of articulate speech, but the interference was declared as to the receiver alone."

As to issue G the examiner of interferences finds :

"For the reasons heretofore stated in construing the issues, this interference is held to embrace a receiver containing an electro-magnet and a diaphragm supported and arranged in close proximity thereto, *and adapted to respond to variations in the electric current passing through the coils of the magnet, when used in connection or combination with a transmitter adapted to create sound producing fluctuations in the electric current, whether said electrical variations, waves, pulsations or undulations represent or are derived from sound waves or mechanical vibrations.* . . .

". . . McDonough's application was filed April 10, 1876, shortly after the grant of Bell's patent, and before his lecture of May 10, 1876, or the introduction and use of the articulating telephone ; so that his efforts in this direction may be regarded as entirely independent of and uninfluenced by Bell's disclosures and inventions.

"It is evident that McDonough represented and claimed for his transmitter more than it had been proved competent to perform, but it is equally clear that as to his receiver it was shown to be capable of carrying into execution this invention and of responding to such electrical waves or pulsations as he was able to transmit. The Office held his instruments to be modifications or variations of the Reis Legat telephone, and with that understanding included him as a party to this interference, thereby admitting that his receiver as described and shown embodied the invention, and that it differed from or was an improvement upon the Reis-Legat receiver.

"Now, it is satisfactorily proved that McDonough made and used substantially the receiver shown in his application, and in connection or combination with substantially the same form or character of transmitter there shown, as early, at least, as May, 1875, for transmitting and reproducing musical tones, and that he was reasonably diligent in the prosecution of his experiments, which eventuated, not in a successful articulating telephone, but in the instruments contained in his application.

"There is some evidence tending to show an earlier conception of this invention, but he cannot derive any benefit therefrom because of his unreasonable delay and want of diligence prior to May, 1875, in carrying into practice his designs.

"It is perfectly evident that, under the law, McDonough cannot be deprived of his right to a patent for such matters as he has shown to have actually invented, diligently prosecuted, and for which he has filed an application (and it matters not that the advance or improvement was but slight and restricted in its application), unless it shall appear that, prior to the date of completion of his invention, another had perfected or had conceived and was diligently prosecuting to completion the same invention.

"Taking, therefore, May, 1875, as the date of McDonough's invention of the receiver in issue, it only remains to be considered whether Bell has proved prior conception, for he does not pretend to have constructed such a receiver prior to July, 1875.

"Upon the evidence submitted it is impossible to find that he had conceived, much less disclosed, the invention in issue in this case. In his disclosures to Blake in October, 1874, no suggestion is made of any change in his system, as illustrated in the 'harp instrument,' except as to the means for transmitting sound vibrations ; and from that time until June, 1875, no further disclosures or experiments were made ; and when the matter was taken up in June, 1875, and the first tangible expression given to his ideas, he used a reed receiver.

"Upon this count, as defined and explained, J. W. McDonough is awarded priority of invention."

Upon all the other issues now involved priority was awarded to Bell, as already stated.

THE DECISION OF THE EXAMINERS-IN-CHIEF.

Gray did not appeal from the decision of the Examiner of Interferences as to any of the issues, except issue G, but acquiesced. Voelker and Edison did appeal. Bell, Gray and Edison appealed as to issue G. It is unnecessary to set out the decision of the Examiners-in-Chief, excepting in so far as it relates to issue G. As to the other issues, it is in accord both as to the construction of the issues and the conclusions of fact with the decision of the Examiner of Interferences, whose decision was affirmed except as to issue G.

As to Bell the Examiners-in-Chief said :

"Bell is the only one of the contestants having patents. Of these, his first, granted March 7, 1876, has been vigorously attacked upon the ground that it does not disclose the invention in controversy, but this question has already been determined by the Office when the patent was granted, when the interference was declared, and when, in Bell *v.* Gray (C. D., 1879, 42), the Commissioner defined the various issues ; and by the courts, in American Bell Telephone Company *v.* Spencer (8 Fed. Rep., 509) ; and Same *v.* Dolbear (15 *ib.*, 448). It is not now therefore to be considered by this tribunal as open."

"Neither will it be necessary for Bell to prove reduction to practice. Having a patent, the law presumes that his invention was complete when he filed his application describing it."

They cite in support of the last proposition the following authorities :

Wheeler *v.* Chenowith, C. D., 1869, 48.
Hammond *v.* Laird, C. D., 1875, 23.
Potter *v.* Holland, 1 Fish, 382.
Cahoon *v.* Ring, *ib.* 397.
Busha *v.* Phelps, C. D., 1876, 116.
Huntly *v.* Smith, C. D., 1880, 182.
Starr *v.* Farmer, C. D., 1883, 34.
S. C., Secretary of Interior's Decisions, C. D., 1883, 116.

The Examiners-in-Chief then cite numerous authorities to show that in an issue between an applicant and a patentee the burden of proof is upon the former, and the evidence to sustain priority over the patentee must show an earlier conception followed by diligence toward reduction to practice, or an actual reduction to practice ; and such evidence must be of the clearest and most satisfactory character. In their decision the Examiners-in-Chief say :

"The issue is in substantially the language of Gray's claim, and its exact scope and meaning have been made the subject of such controversy. The controversy has arisen from the fact that the issue states the combination as a telephone receiver, and its object, the reproduction of both the pitch and quality of the transmitted sound.

"On this account it is contended on the part of Bell that there must be read into the claim a device for transmitting quality, that is, an articulating transmitter, and on the part of Gray that it is sufficient if the transmitter transmit 'rythmical vibrations of any and every description, including the tones of the human voice and articulate speech.' McDonough, it seems, agrees with Bell.

"The Examiner, reasoning from the premise that while the other parties show articulating transmitters, neither McDonough nor Edison does, and Gray contemplates the transmission of sounds produced either by mechanism or the human voice, reaches the conclusion that the issue embraces any receiver consisting of the elements named, whether used in connection with an articulating or other transmitter, and whether it reproduces quality or not.

"'The construction given the claim,' [he says], 'the combination of the electromagnet, the diaphram, and an electric circuit over which sound-producing currents are transmitted, is in harmony not only with the express declaration of the applicant upon whose demand for a patent these proceedings were instituted, but also with the action of the Office in including the applications of Edison (No. 148) and McDonough.

"'If an articulating transmitter forms an essential element of Gray's claim, these applications could not properly have been joined in the interference, for neither shows or describes such an invention.'

"It is, however, necessary for the determination of the issue that some kind of transmitting instrument be used to throw sounds upon the line. The terms of the issue require this, and also that the quality of such sounds shall be reproduced. Hence, if it be possible, some means must be adopted to bring all the parties within these terms, but to do this the manifest requirements of the issue should not be disregarded.

"It is held by the examiner, as above quoted, that a limitation of the issue to an articulating transmitter would do violence to the direct statement of the applicant whose claim forms the basis of this issue, but this does not necessarily follow. Upon examination of Gray's specification it appears that he states the object of his invention to be 'to provide an apparatus capable of accurately reproducing in an electric circuit not only the different tones but the pitch and quality of sounds, whether produced by mechanism or the vocal organs.' In fig. 2 he shows his receiver in connection with a series of vibrating reeds, each transmitting a tone of different pitch, which may be operated simultaneously or successively. It is not intended to transmit quality with this apparatus, but the statement is simply that the *tones* are transmitted and reproduced. When, however, the arrangement shown in fig. 3 is described, in which receiver and transmitter are alike, it is expressly stated that 'articulate words spoken in one instrument will be accurately reproduced in the other, both as to pitch and quality as well as *tone*.' It is upon this latter description that the claim is based, for after stating the elements of the combination he uses substantially the language employed in describing fig. 3, whereby sound thrown upon the line may be reproduced accurately as to tone, pitch and quality.

"It thus appears that not only is no violence done to Gray's statement by such a limitation of his claim, but that a fair inference to be drawn from considering it in connection with his specification is that he himself so intended to limit it, else why insert so carefully the word 'quality'? The fact that his receiver is also capable of reproducing other sounds should not be decisive in construing the issue. The greater includes the less. If a given apparatus transmit and reproduce quality, it will likewise pitch and tone, and the issue is not who first constructed a device to reproduce these, but these in conjunction with quality.

"As to Edison, it is true that his application No. 148 does not show or describe an articulating transmitter, and that he, therefore, does not transmit quality ; neither does McDonough. It is, however, none the less true that Edison's application No. 145 does not disclose such a transmitter, but the commissioner, when these issues came before him for construction and reformation, held that issue E, which includes and is, in fact, based upon Edison's claim in No. 145, embraces a devise which was a necessary part of the means for carrying out the method involved in issue A, *i. e.*, the transmission of articulate speech. Following his lead, this tribunal made an articulating transmitter an element of that issue, and such a course is equally proper here, for this issue was similarly construed by the commissioner in that same decision.

"In considering it he says:

"'It is true that this receiving device is but the transmitting device of "Interference F" reversed, but the fact that the device as used in "interfence G" would enable an undulatory current of electricity to reproduce, at the point of delivery, the same sound vibrations which had been caused *by articulate speech* at the starting point, was not enough to suggest to the skilled workman or electrician that the same device would, if reversed, enable the sound vibrations caused *by the spoken word* to cause such variations of the electric current as to reproduce at a remote point of the circuit the same sound vibrations.'

"Language could not more plainly indicate than this the guiding principle of this entire proceeding, and it was not only the intent of the Office that the invention of the speaking telephone should be tried here, but it was also the intent of the parties. Their testimony has all been directed to this end, and with the exception of Gray, they are all still insisting that they invented not only the art but the apparatus. At the beginning of this controversy Gray made the same contention and filed simultaneously three applications: one for the method, one for the transmitter and one for the receiver. That he has withdrawn f om the contest, except as to this issue, does not entitle him to have one of these applications used as a basis for an interpretation which neither he nor the other parties originally intended. Bearing this intent in mind, then, and the further fact that no other one of the issues will permit it, where else shall the question of priority as to the receiver be determined if not under this issue?

"It was pertinently remarked by counsel for McDonough, that without an articulating transmitter the receiver of this issue could not practically be tested, and its capability of reproducing indiscriminately the quality of any and all sounds could not therefore be known. It may as pertinently be ask d how, then, can the question of priority be decided upon an issue whose terms require the transmission of quality unless the only instrument which has this capacity be included, *i. e.*, an articulating transmitter?

"To sum up briefly, it appears that this interference was sought by the parties to determine who invented the speaking telephone, the art and apparatus for carrying it out; and the declaration was made by the Primary Examiner for the same purpose. The Commissioner, upon a proceeding to reform the issues, recognized and confirmed this, the parties accepted it, and the testimony was taken with it in view. Gray formerly insisted, and Edison and McDonough still insist, that not only the art is of their invention, but the apparatus also, and it is only by including an articulating transmitter in this issue that the question of priority as to the receiv r can properly be determined.

"If the construction of the issue given by the the Examiner of Interference is to prevail, and priority be awarded to a party who had no articulating transmitter, it would result that an experimenter who had tried to transmit speech and failed, or one who had never tried, should so dominate the art that an inventor who had worked out the idea, patented his process of carrying it out, introduced it to the public and put it into extensive use, could not practice the art which he had created without being tributary to his unsuccessful rival. . . .

". . . Stated more specifically his (Gray's) proposition is :—

"'That as certain devices he mentions are not only capable of acting as receivers of articulate speech, but when properly organized as to their circuit connections will operate both as receivers and transmitters of articulate speech, . . . it makes no difference whether Gray knew or not that his instruments possessed this quality so long as they did possess it. Gray knew that his receivers would reproduce the quality of sounds transmitted through the line, and he believed that if he could transmit articulate speech it would probably be reproduced, but he at that time did not have the conception of such a transmitter.'

"That is, indeed, a shadowy theory upon which to rest his case, and the most conclusive answer to it is that of counsel for McDonough, before quoted, that he could not know his receiver would reproduce speech unless he was able to test it, and this could only be done by a speech transmitter. If he did not know this, how could he impart the knowledge to the public, and how obtain a patent?

"It is a prerequisite to the grant of a patent that it shall convey to the public the knowledge necessary to enable it to practice the invention, and it is just here that Bell and Gray differ. If Gray had obtained a patent for his instruments which he now says can transmit and reproduce speech, the public would not have been in any manner enlightened as to this art. He stands in an entirely different light from Bell, and the decision of Mr. Justice Lowell, in American Bell Telephone Company *v.* Spencer, *infra*, does not help him. It was not held in that case that it was enough for a person to have constructed an apparatus capable of doing a certain thing although he did not know it. Another and a controlling element entered into the decision, that a mode of doing this thing had been pointed out, and that the apparatus operated after this mode.

"'There is some evidence,' say the court, 'that Bell's experiments with the instrument described in fig. 7 before he took out his patent were not entirely successful: but this is now immaterial, for it is proved that the instrument will do the work, whether the inventor knew it or not, *and in the mode pointed out by the specifications*.'

"Gray had not only not pointed out how his receiver could reproduce speech, but he did not know himself until taught by Bell's patent.

"In this view of the case it will not be necessary to look into Gray's evidence, for it is admitted that he had never transmitted speech before the date of Bell's patent or application, and in the view we take of this issue it is immaterial when the devices upon which he now relies were constructed.

"The case of McDonough is somewhat similar to Gray's, though with this important difference, that he still insists that he is the inventor of the speaking telephone. His case, as stated by his counsel, is as follows:

"'We submit, therefore, that Mr. McDonough was the original and first inventor, because he had in 1867 practically used the magnet and diaphragm in combination for a receiver; had in 1871 conceived of the use of said combination for articulate speech; had reduced the same to a drawing, and in April, 1874, attempted to embody the same; being prevented by sickness he went to Europe; returning in the fall of 1874, he began in April, 1875, again to put his receiving apparatus together, and combined and used it with a transmitter in May, 1875, and applied for his patent April 10, 1876.

"All these acts of McDonough may be admitted, and yet priority cannot be awarded to him unless he can be shown to have had an articulating transmitter Upon this depends his entire case, and it becomes important to determine what he really had."

The history of McDonough's efforts and devices is then set out, following a line similar to that of the Examiner of Interferences. In conclusion the Examiners-in-Chief add :

"Upon the whole, McDonough's proofs cannot be held to be sufficient to overcome Bell's record dates. We have seen that a party contesting the right of a patentee must show completed and perfected apparatus. That McDonough did not have this is clear. Had a patent been granted to him for it as described in his application or as experimented with in June, 1875, the public would have been no wiser than before. It still would have been ignorant of the method and apparatus for speech transmission, for no instrument working upon its principle of making and breaking contact can accomplish that result. In this respect McDonough gave no more to the world than Reis. As was said of Reis, by Mr. Justice Lowell, in American Bell Telephone Company *v.* Spencer, above, a century of McDonough would never have produced a speaking telephone."

GRAY'S CASE.

As noticed several times, Gray acquiesced in the decision of the Examiner of Interferences as to all the issues except G.

It is important to understand why he pursued this course. This decision was rendered July 21, 1883. His present petition was not filed until December 30, 1886, three years and five months after the decision. Even then the petition was filed with a request that it should not be acted upon until further motion was made, and no notice of its filing was served upon the adverse parties. It is well settled that a petition filed and presented under such circumstances is of no avail for any purpose whatever. It performs no function. In the mean time, rights of other parties are accruing or vesting from lapse of time, statutes of limitation run, etc. It is only from December 1, 1887, that this petition can be justly said to have been filed, the date at which the Commissioner directed all matters relating to these interference cases to be set down for disposition.

Why, therefore, did Gray acquiesce in the decision and wait so long before action?

It appears from the record, and about this there is no dispute, that for a long time after Bell's patent issued, Gray conceded and acknowledged that Bell was the first original inventor. He also regarded the invention as a trivial and unimportant one, a scientific toy. As early as November 1, 1877, he had written his attorney, Baldwin :

"Bell's talking telegraph.—It only creates interest in scientific circles, and as a scientific toy ; it is beautiful, but we can already do more with a wire in a given time than by talking. so its commercial value will be limited."

This was after Gray had seen Bell's telephone at the Centennial in 1876, at Philadelphia, and had heard it talk. In letters to Mr. Bell and others, in lectures at Chicago and elsewhere, in 1876 and 1877, Gray publicly and privately conceded priority of the invention of the telephone by which articulate speech could be transmitted to Bell, and awarded him the honor of being the inventor. That he did these things is fully conceded by Gray.

Gray was a prolific inventor, and had prior to 1876 taken out a number of patents. These related to multiple and harmonic telegraphy, among other things. Some of these inventions subsequently became the foundation of his claim to have invented the telephone ; for instance, his patent No. 166,095. At an early date he had interested a Dr. Samuel S. White in his inventions. At the time Dr. White became interested Gray had never succeeded in transmitting speech, but, undoubtedly, was speculating upon the subject. Recognizing Bell as the inventor, Gray filed no application for a speaking telephone until October 29, 1877, although he says in a statement prepared and published in April, 1878 :

"As early as March, 1874, Dr. Samuel S. White, of Philadelphia, had purchased an interest in all my telephonic inventions which I had made or might thereafter make."

That this would include and was subsequently made to include Gray's caveat, cannot be doubted, as subsequent important transactions and Gray's evidence abundantly show.

Being thus jointly interested, Gray and White concluded to conduct their business under a corporate organization, and by

articles dated May 26, 1876, they organized "The Harmonic Telegraph Company," with a capital of five thousand shares one hundred dollars each; of which Gray had twenty-four hundred and seventy-five; White, twenty-four hundred and seventy-five; Andrews, about fifty, and some others a few shares.

Evidently this organization looked to the exploiting of Gray's patents, and did not contemplate the subjects of telephones so much as the introduction of telegraphic inventions; for at this date Gray regarded the telephone as a toy and Bell as the inventor.

There existed at this time the Gold and Stock Telegraph Company, which controlled the inventions of Edison, Dolbear and others. In the fall of 1877, Gray and White, representing the Harmonic Telegraph Company, opened up negotiations with the Gold and Stock Telegraph Company for the sale to them of all inventions Gray had made or might make thereafter, relating to speaking telephones. By this time it had been demonstrated that the telephone was not a toy; its commercial importance was beginning to be understood, and it was being introduced.

In this condition of things, being under the belief that Bell was the first inventor, having organized the Harmonic Telegraph Company, and negotiating for the sale of his telephonic inventions to the Gold and Stock and the American Speaking Telephone Company, about to be organized, Gray filed his applications Nos. 1, 2 and 3. October 29, 1877. He says in his affidavit of November 9, 1885:

"Being in this belief, I did not take steps to file my application upon my caveat promptly, but the matter rested without any application until November 1877. This long delay will be understood, in view of what I have already stated. Some time prior, however, to the filing of said application, it was suggested by the American Speaking Telephone Company, under the idea that it was the owner of said (my) caveat, *that some advantage or benefit might be derived from it.* [That is, Gray filing his applications.] I accordingly filed my applications. This was my act thus done, and done by my counsel at the request of said company."

He is mistaken about the suggestion coming from the American Speaking Telephone Company, for that was not organized at the date he filed his applications. It came either from his own company, the Harmonic, or else from the Gold and Stock or the Western Union. It was probably the latter companies, which had become owners of Edison's, Dolbear's and other inventions, and who knew that sooner or later a bitter controversy must arise between themselves and the Bell Telephone Company as to the validity of Bell's patents. It was probably these latter companies, which were then negotiating with Gray and White, as the owners of these inventions, who advised Gray to file his applications, expecting "that some advantage or benefit might be derived from it." These companies expected to become interested in Gray's inventions as the result of pending negotiations, and thus, having control of Gray's inventions, as well as Edison's, Dolbear's and others, they would be better equipped to enter the legal lists with the Bell Company. There is no other possible explanation of Gray's course in filing his three applications and making the oath to them, when he, as he now testifies, still believed that Bell was the first inventor. It was long after this that Gray changed his belief, though he has not seen proper to state the precise time when the change occurred. As will presently be seen, up to and long after the decision of the Examiner of Interferences, he conceded priority to Bell, except as to issue G.

The American Speaking Telephone Company was organized pursuant to an agreement of date November 17, 1877, between the Harmonic and the Gold and Stock Companies and the Western Union Telegraph Company. The Harmonic Company was to transfer to the former,—

"all existing and future patents and inventions owned and controlled by it or which may thereafter be owned and controlled by it, so far as the same *relate to speaking telephones*, more particularly the *patents and inventions, and right to future patents and inventions of Elisha Gray.*"

The Gold and Stock Company were in like manner to transfer to the American Speaking Telephone Company the patents and inventions, present and future, of Amos E. Dolbear.

These agreements were subsequently carried out. The American Speaking Telephone Company organized under articles dated December 1, 1877, and, the transfer made, Gray received large blocks of stock in the new company, was a director thereof, and also held important and responsible positions for the company. It is somewhat difficult to understand just what position Gray assumes with reference to these transactions. He now declares that for some years he *believed* that he had transferred his telephonic inventions, including those now in controversy, and virtually that all the parties with whom he dealt *believed* that they had acquired them. He does not assert that he did not *intend* to assign them and transfer them to the Harmonic Company, of which he was an officer and stockholder, or that they were not intended to pass to the American Speaking Telephone Company. But he appears to simply assert that the formal conveyances from himself to the former company were not in law sufficient, because the inventions were not specifically named or described or because the contract was of an executory character. Precisely what he relies on is not definitely known. But that he believed he had assigned and transferred them, and that he received large and valuable consideration for the supposed transfer is as clearly shown as that the parties receiving the transfers believed they were thereby acquiring the right and title and paying for them.

This is shown by Gray's own statements and testimony and by the subsequent litigation between Gray's supposed assignees and the Bell Company, both in the Patent Office and in the courts, in all of which Gray took part, both as party and as witness, *believing* that he had invested the American Speaking Telephone Company and the Western Union Telegraph Company with the title to his telephone inventions. What were these contests about? The telephone. To suppose that this contest, extending until recently decided in the United States Supreme Court, was one that did not include Gray's telephone, and that those great companies, as well as Gray, were resisting the Bell Company in any other belief than that they owned Gray's inventions, is incredible.

Thus organized and controlling the several inventions and patents of Gray, Edison and Dolbear, the American Speaking Telephone Company began to put out telephones in the winter of 1877-8, and before the close of 1879 had put more than twenty thousand into commercial use. This company paid the expense of preparing and presenting Gray's applications, the erection of necessary telephone lines, material, bells, batteries, etc.

Peter A. Dowd was an agent of the American Speaking Telephone Company, and was engaged in their telephone business. In September, 1878, the Bell Company at Boston sued him and the American Speaking Telephone Company and the Western Union Telegraph Company, as infringers of the Bell patents, and thus the expected contest was begun. The defence of the suit was assumed by the Western Union and associated companies. It was determined to set up Elisha Gray as a prior inventor of the speaking telephone and of various important features of telephones then in use. Gray prepared a printed statement of all he had done toward the invention.

It occupied nearly 100 pages. While it does not appear that he had changed his opinion as to the original inventorship, the importance of the pendency of his three applications in the Patent Office and of the interference between them and Bell's patents, which had been declared in the mean time, is apparent. The answer to the Bell Company suit justified under Gray. Every exertion appears to have been made to present Gray's inventions in the strongest light. Besides furnishing the statement alluded to, Gray went to New York and spent most of the winter and spring of 1878-9 in assisting in the preparation of the defence. He also gave his testimony, and in the present procedure it is not pretended that he can add anything or throw any new light upon the subject or history of his invention. He has disclosed everything and has no more to tell.

There were thus pending contemporaneously two contests or proceedings, the interferences in the Patent Office and the Dowd suit in the United States Circuit Court for the District of Massa-

chusetts. The taking of evidence progressed, but that in the Dowd case was completed first. It was practically closed on the 19th of September, 1879, including the complainants' evidence-in-chief, the defendants' evidence-in-chief and the complainants' evidence in rebuttal. No question is made but that up to this date the contest was most vigorously and bitterly conducted, the Bell Company claiming under the Bell patents and the Western Union having control of Edison's, Dolbear's and Gray's inventions, as was supposed and believed. Eminent counsel represented the respective parties, and the litigation became a matter of public notoriety and its determination one of public interest.

At this stage of the litigation, when the evidence had been concluded and counsel were in condition to take a definite survey of the facts, counsel, including Mr. Gifford, advised the Western Union and the associate companies that the Bell patents were valid and that the defence must fail. But valuable improvements had been made upon the speaking telephone which were deemed important to the commercial success of the original invention, and the Western Union and associate companies controlled these,—such as Edison's carbon telephone, the Page patent covering the induction coil, etc. With impending defeat before them, the Western Union Company proceeding upon the basis of these valuable improvements, opened negotiations with the Bell Company to compromise the litigation and unite all patents relating to the speaking telephone upon terms to be agreed upon. Such an agreement could not well have been proposed or made unless it had been believed that Gray was not the first inventor, and also that the Western Union had acquired his inventions, for his inventions had been those under which they had justified, and to settle that litigation, leaving his inventions out, would have been absurd.

This settlement was effected and a preliminary memorandum was executed on September 27, 1879. This preliminary agreement was a voluminous instrument settling and determining the rights of the various parties in and to these various inventions, and determining in what manner the telephone business should be conducted, etc. It is not necessary to set the agreement out with any great particularity. It appears that when this preliminary memorandum was made it contemplated that it should subsequently be reduced to a more complete and perfect form, which was afterward done, of date November 10, 1879. There is no claim that there is any essential difference between the memorandum and the subsequently executed formal instrument, except in Article 16, which provides:

"The existing suits and interferences shall be disposed of as counsel of the parties of the first and second parts may advise to recognize and protect the rights of the respective inventors to their several inventions, subject to the orders of the courts and the decisions of the Patent Office."

This paragraph in the memorandum read as follows:

"The suits and the interferences shall be disposed of as counsel for the respective parties may advise to carry out the purpose of this agreement, so long as it shall continue in force."

Article 17 provided that the contract should go into effect as of November 1, 1879, and remain in force for seventeen years thereafter. Pursuant to this contract a decree was entered in the Dowd case on the 4th of April, 1881, adjudging Bell's patent to be valid and perpetually enjoining the infringement of the same. This decree recites the fact that it is by consent of parties.

The evidence in the Dowd case was, by stipulation of all parties to the interference proceedings transferred and introduced in the interferences as evidence to be used and considered in those cases.

The effect of the contract of November 10, 1879, by which the Dowd suit was settled, was to invest the Bell Telephone Company with the ownership of all the telephone inventions, which at that time were supposed and believed to include Gray's inventions, and obligated it to pay to the Western Union Telegraph Company twenty *per centum* of all rentals or royalties received or rated as paid by licensees or lessees for speaking telephones, and also twenty *per centum* of the net profits of the manufacture of telephones made in the United States for export.

As further explaining Gray's course in failing to file his applications sooner than he did and also in making the subsequent concessions hereinbefore referred to in favor of Bell as the prior inventor, it is proper to call attention to some additional circumstances which appear in the history of the matter.

Bell's application was prepared and executed January 20, 1876. Gray's caveat was prepared and executed February 14, 1876, and both were filed in the Patent Office on the same day, viz, February 14, 1876. The Examiner at that time in charge of the division to which they were referred, following what appears to have been the practice theretofore, treated Gray's caveat as having been filed first, within the meaning of the statute, and issued notices to the parties, advising them of the fact of an apparent interference between the application and the caveat, and required Gray to proceed and file his application within the ninety days if he desired to avail himself of the caveat.

Bell's attorneys at once made an inquiry of the Office to know the precise date on which the caveat was filed. This was a matter which of course they were entitled to know, and finding that the date of filing the caveat was the same as that of Bell's application, they insisted that it was proper to determine which was in fact filed first, regardless of the date or day. This matter was then referred to the Commissioner, who instituted an investigation and ascertained to his satisfaction at that time that Bell's application was filed first, and as matter of law he held that the caveat was not filed within the time or before the application, within the meaning of the patent law, and directed that the notices which had been theretofore issued to the parties should be withdrawn, and that Bell's application should not be suspended to await action on Gray's part.

This investigation made by the Commissioner at that time appears to have been conducted as any other investigation would be in the Patent Office under similar circumstances—*ex-parte*. It was instigated, of course, by Bell's attorneys. Gray, however, had he manifested the same diligence, could have set on foot a similar investigation and been heard; indeed, the record discloses the fact that Gray's attorney, on March 3, 1876, advised his partner, S. S. White, of the situation, and added:

"We could still have an interference by Gray's coming down to-morrow and promptly filing an application for a patent. If you want this done, telegraph me in the morning on receipt of this and I will have the papers ready in time to stop the issue of Bell's patent; but my judgment is against it, as Gray made the invention, as I understand it, while here, after Bell's application was sworn to. He may, however, have invented the resistance part of the application at an earlier date, and Bell's claim is for the system of graduated interruptions by a varying resistance instead of the abrupt interruptions, as I have mentioned.
(Signed) WM. D. BALDWIN."

Neither Gray, nor his partner White, responded to the suggestion of this letter. No application was filed, and Bell's patent issued.

Quoting now from Gray's affidavit of November 16, 1885, this explanation of his inaction is given:

"At the Centennial Mr. Bell exhibited a telephone which transmitted articulate speech. I witnessed the exhibition. He did not use a liquid transmitter on this occasion, but used an instrument very nearly resembling the receiver of my invention. I communicated this fact to my counsel and requested his opinion as to how my case stood in view of said fact, *and he informed me that practically my claim was defeated*, that Bell's application was filed on the same day as my caveat, and that Bell having made an instrument that successfully transmitted articulate speech, he occupied a better position and would undoubtedly succeed.

"Upon this advice of my counsel and my friend I acted. I had the fullest confidence in him. I believed that he was not only faithful in all respects, but that he had the necessary learning, ability and experience to advise me rightly. In the latter it seems I was mistaken, but I did not for a long time find out the mistake, and did not know that the advice thus given was wrong and not in accordance with the law, as I am now advised.

"All my subsequent correspondence, admissions, statements and interviews must be construed with this in mind, and in view of the fact that I supposed I had parted with all my pecuniary interests in this and other inventions, and was therefore only interested as to my reputation as an inventor, and it seems my counsel, so called, had the same idea in view, as stated in his letters of October 24 and 29, 1881, as set forth in his last affidavit in which he wrote as follows:

"'I am devoting my argument more to a vindication of your position than to attacking your adversary, though I am stating some facts in regard to Bell and Edison very plainly.' In the letter of October 29, 1881, he says: 'Enclosed find an advanced copy of my argument in your behalf in the speaking telephone interference case. My object has been mainly to place you right before the public on the scientific side of the question. I hope I have succeeded, but I am not proud of the performance."

This state of mind on the part of Gray appears to have continued down to a point of time which was later than the decision of the Examiners-in-Chief in the interference proceedings.

Mr. Baldwin was Gray's attorney in preparing his caveat and his applications, and also in conducting the interference. Baldwin says that upon the settlement of the Dowd case, in November, 1879, it was understood and agreed that the questions of priority pending in the interferences involving a personal pride and feeling to the parties should be settled by adjudication in the Office.

"That particular plan was in accordance with a correspondence between Mr. Gray and myself. The plan set forth in that correspondence was faithfully followed by me throughout to the best of my ability. Moreover, Mr. Gray was kept advised from time to time of the plan on which the argument and appeal were made."

The record is very satisfactory that Mr. Baldwin kept his client, Mr. Gray, constantly advised of what was being done in the cases. The correspondence is produced and not controverted. The relations of the Bell Telephone Company to the applications of Gray, Dolbear and Edison, which were the result of that settlement, were thoroughly understood by Gray at the time. In a printed brief prepared by Gray's counsel in the interferences it was stated that articulate speech had not been transmitted by either of the inventors or others prior to the Bell patent; that Bell's first reduction to practice was after his patent issued, and by means of a liquid transmitter. It was also stated in the brief:

"When, however, in the course of subsequent litigation, the fact was developed that as between Gray and Bell, the latter really was the first to conceive the invention of transmitting articulate speech and to reduce the invention to practice, Gray voluntarily came forward, like the straightforward, fair-minded man that he is, and conceded that fact to his rival. We shall therefore retire from the contest over the issues in cases A and B, so far as relates to the question of electrical transmission of articulate speech. The ground was so thoroughly cultivated then (in the Dowd case), that it was not seen where it could be improved by harrowing it again, and the entire record was accordingly stipulated into this case (the interference), that we might have the benefit of the numerous and valuable facts developed. The fifth claim of this patent has since been interpreted and sustained by the courts as broadly as Bell himself could desire in the recent case of American Bell Telephone Company *v.* Spencer, 20 O. G., 229."

It also appears that copies of this brief were furnished Gray by his counsel, Baldwin, of which he acknowledged the receipt in a note dated New York, November 14, 1881, as follows:

"*Dear Baldwin,*—I received the patents and also the copy of your brief The letter was a very able document, and you did yourself 'proud.' I would like a few copies for distribution."

In response to this fifty copies were sent to Gray, and it does not appear that he ever expresssed any disapproval of its contents. After the decision by the Examiner of Interferences Mr. Baldwin advised him in a note, "My opinion is to appeal on the receiver cases and let the rest go." This course was either approved or acquiesced in by Gray, and the appeal was subsequently taken as explained from the decision so far as it is related to the receiver, issue G, with the results heretofore set forth, so that it must be recognized as one of the established facts in the present matter that Gray's recognition of Bell as the first original inventor, as explained above, was made deliberately and publicly.

In order more fully to understand the question of collusion, as urged in these proceedings, it is necessary to state, in this connection, that prior to November 2, 1880, negotiations had been entered into between the American Bell Telephone Company and McDonough, with reference to the purchase by the company of McDonough's inventions in telephony, and on the second day of November, 1880, a written contract was executed between those parties of which the following is a copy:

"This agreement, made the second day of November, A. D., 1880, by and between James W. McDonough, of the first part, and the American Bell Telephone Company, a corporation, of the second part, witnesseth:

"In consideration of *five thousand dollars*, paid by said corporation to said McDonough, the receipt of which is hereby acknowledged, it is agreed as follows:

"If said McDonough on his inventions shall obtain a *valid* patent, covering broadly the art of transmitting articulate speech by electricity, he shall assign the same to said corporation, and said corporation shall thereupon pay him the sum of *two hundred thousand dollars* therefor. If said McDonough, on his own inventions, obtains a *valid* patent, covering broadly variable-resistance contact transmitters for electric speaking telephones, he shall assign the same to said corporation and said corporation shall thereupon pay him the sum of *fifty thousand dollars*.

"If said McDonough on his invention shall obtain a patent covering broadly magnetic receivers for electric speaking telephones, he shall assign the same to said corporation and said corporation shall thereupon pay him the sum of *fifty thousand dollars*.

"It is understood that Mr. McDonough is not to take out foreign patents in such a way as to shorten the life of the United States patents, which, if granted, will be subject to this agreement.

"Signed and sealed at Boston on the first day above written.

"*This agreement is not to be taken as any manner of admission by either party, as to the validity or invalidity of claims made by the respective parties*

("Signed) THE AMERICAN BELL TELEPNONE COMPANY.
By W. H. FORBES, *President*.

"In presence of C. EMERSON as to W. H. F.
(Signed) JAMES W. McDONOUGH. [Seal]

"Received $5,000, as within, November 2, 1880.
(Signed) JAMES W. McDONOUGH."

Attention is called to the closing paragraph, which clearly indicates that neither party contemplated assisting the other in procuring their respective patents, but that each party evidently undertook to look after his own interests in the prosecution of his claims.

With this statement of the facts relating to Gray's case I now proceed to consider the merits of his petition. In advance it must be understood that the case is before me upon a petition for rehearing, in which I am asked to set aside all of the orders heretofore made and to reinstate the cases for reconsideration upon new and additional evidence and upon the merits broadly. The decision which is sought thus to be set aside was rendered by Mr. Commissioner Butterworth in March, 1885. The subject was allowed to pass over the entire administration of Mr. Commissioner Montgomery for presentation or consideration other than to file the petition with an indication that it should not be acted upon until further motion should be made, and it now comes before me, the second successor of the officer who decided the case.

Rule 144 of the Office, which has been in force during all this period, provides as follows:

"Cases which have been deliberately decided by one commissioner will not be reconsidered by his successor except in accordance with the principles which govern the granting of new trials."

An attempt is made in argument to show that this case was not deliberately decided by Commissioner Butterworth, for the reason that in his decision he made use of the following expression:

"If on examination of the evidence and consideration of the arguments I had become convinced that the findings and decisions of the Examiners-in-Chief were erroneous, or if a serious doubt in that behalf had been raised in my mind, I would have felt constrained to leave the case undecided, to be reheard by my successor. Had I reached a different conclusion it would have been desirable that the reasons for overruling the decision of the board should be stated at length"

I am not able to see the force of the argument that this expression indicates that Mr. Butterworth's decision was not one deliberately made. On the contrary, if any inference can be drawn from it, it is that the case was elaborately considered and deliberately determined, and that he had no doubt about the result which should be reached, and accordingly announced his decision. The record shows that the case was argued at length and was given great consideration, and it is this, which in my judgment, determines whether a case has been deliberately decided or not. It follows, therefore, that the case is not before me upon its merits, and I am not in a situation to be called upon to grant a rehearing upon a mere preponderance of evidence, as if the case were before me originally, where the preponderance of evidence would prevail; but I am to bear in mind that this controversy has extended through a period of years in the Office, that it has passed through all of the tribunals, and with a single exception, viz., as to issue G, the decisions have all been uniformly in the same direction, and a case must now be presented which justifies the exercise of a judicial discretion before a rehearing can be granted, and this must be done by evidence either of error an in the conclusions of fact or in the application of the law of a very clear and satisfactory character.

At every stage of the contest in this Office, one of the serious and important questions has been the effect and legal construction to be given to the Bell patent of March 7, 1876. The Examiner of

Interferences felt concluded by the construction which had been put upon that instrument by the commissioner and the courts, evidently referring to the Spencer case. The same is true of the Examiners-in-Chief, who cite the Spencer case and the Dolbear case. Before me it has been urged with great force of argument that those cases were not authoritative: that Bell's patent was not a patent for a telephone, but for a multiple telegraph, and that Bell in fact had never invented the telephone. But I am relieved of any further consideration of these questions by the recent decision of the Supreme Court in the Telephone cases, 126 U. S., where that tribunal has finally and definitely settled such questions.

That court says:

"In the present case the claim is not for the use of a current of electricity in its natural state as it comes from the battery, but for putting a continuous current in a closed circuit into a certain specified condition, suited to the transmission of vocal and other sounds, and using it in that condition for that purpose. So far as at present known, without this peculiar change in its condition it will not serve as a medium for the transmission of speech, but with the change it will. . . . We see nothing in Morse's case to defeat Bell's claim; on the contrary, it is in all respects sustained by that authority. It may be that electricity cannot be used at all for the transmission of speech, except in the way Bell has discovered, and that therefore, practically, his patent gives him its exclusive use for that purpose; but that does not make his claim one for the use of electricity, distinct from the particular process with which it is connected in his patent. It will, if true, show more clearly the great importance of his discovery, but it will not invalidate his patent. But it is insisted that the claim cannot be sustained, because when the patent was issued, Bell had not in fact completed his discovery. While it is conceded that he was acting on the right principle and had adopted the true theory, it is claimed that the discovery lacked that practical development which was necessary to make it patentable. In the language of counsel, 'there was still work to be done and work calling for the exercise of the utmost ingenuity, and calling for the very highest degree of practical invention.'

"It is quite true that when Bell applied for his patent he had never actually transmitted telegraphically spoken words so that they could be distinctly heard and understood at the receiving end of his line; but in his specification he did describe accurately and with admirable clearness his process; that is to say, the exact electrical condition that must be created to accomplish his purpose, and he also described, with sufficient precision to enable one of ordinary skill in such matters to make it, a form of apparatus, which, if used in the way pointed out, would produce the required effect, receive the words and carry them to and deliver them at the appointed place. The particular instrument which he had, and which he used in his experiments did not, under the circumstances in which it was tried, reproduce the words spoken so that they could be clearly understood; but the proof is abundant and of the most convincing character, that other instruments, carefully constructed and made exactly in accordance with the specification, without any additions whatever, have operated and will operate successfully. A good mechanic with proper skill in matters of the kind can take the patent and by following the specification strictly can without more construct an apparatus which, when used in the way pointed out, will do all that it is claimed the method and process will do. . . .

"The law does not require that a discoverer or inventor in order to get a patent for a process must have succeeded in bringing his art to the highest degree of perfection. It is enough if he describes his method with sufficient clearness and precision to enable those skilled in the matter to understand what the process is, and if he points out some practicable way of putting it into operation. This Bell did. He described clearly and distinctly his process of transmitting speech telegraphically by creating changes in the intensity of a continuous current or flow of electricity in a closed circuit, exactly analogous to the changes of density in air occasioned by the undulatory motion given to it by the human voice in speaking. . . .

"The apparatus as 'herein-described,' which is included in the claim, is undoubtedly one in which an electro-magnet is employed and constructed 'substantially as set forth' in the specification. One acting on the variable resistance mode is not described further than to say that the vibration of the conducting wire in mercury or other liquid included in the circuit occasions undulations in the current; and no other special directions are given as to the manner in which it must be constructed. The patent is both for the magneto and variable-resistance *methods*, and for the particular magneto *apparatus* which is described, or is equivalent. There is no patent for any variable resistance apparatus. It is undoubtedly true that when Bell got his patent he thought the magneto method was the best. Indeed, he said in express terms he preferred it, but that does not exclude the use of the other if it turns out to be the most desirable way of using the process under any circumstances. Both forms of apparatus operate on a closed circuit by gradual changes of intensity and not by alternately making and breaking the circuit or by sudden and instantaneous changes, and they each require to be so adjusted as to prevent interruptions. If they break it is a fault, and the process stops until the connection is restored."

It is to be observed that in so far as the Supreme Court gave a construction to the Bell patent and held that it disclosed the invention, they were united and there was no dissenting opinion.

It has thus been established in my judgment definitely and finally that Bell's patent discloses the invention of the telephone, covering both the method and the apparatus,—one composed of a transmitter, a closed circuit and a receiver; that this patent relates back to the date of the application, and also to the date of its execution, viz., January 20, 1876, as the first original date of conception. It does not follow, of course, unless established by other evidence, that Bell was the first inventor, or that he was an original inventor. But whoever attempts, either in these interference proceedings or in an infringement suit or suits, such as those decided in the Supreme Court of the United States, to antedate Bell's invention and establish an earlier invention, must prove by clear and satisfactory evidence a prior conception and prior reduction to practice to the date of Bell's application, or that having made an earlier conception than he did, such inventor diligently prosecuted it to a reduction to practice. These propositions may be supported by innumerable decisions of the Commissioner and of the courts, but I see no occasion to cite them.

INTERFERENCES A, B, C, E, F.

First comes the inquiry whether there is anything submitted to me in the record which justifies me in reaching a conclusion that there was any error in the action of the Examiners-in-Chief with reference to the date of Gray's invention, or whether in fact he ever did invent the telephone. In this consideration I exclude for the present issue G, which relates to the receiver.

A most careful and laborious examination of the evidence and arguments submitted failed to impress me with any want of satisfaction in the facts as found by the Examiner of Interferences. It is conceded by all parties that Gray's caveat, prepared and filed February 14, 1876, was the first description he ever made of the invention covered by the issues under consideration. Prior to that date the subject was evidently one of speculation and experiment. As is said by the Examiner of Interferences:

"His energies were directed exclusively to the transmission of musical tones and their utilization for telegraphic and other purposes, no attention being given to instruments for the *reception*, transmission and *reproduction* of articulate speech until along in February, 1876, and although he claims to have had some conception of the *possibilities* late in the fall of 1875 he neither disclosed them to others nor clothed them in any fixed and positive form until he made the sketch for his caveat, February 11, 1876."

Gray says:

"I was *convinced* that the receiver would produce articulate words, inasmuch as it *seemed* to be capable of reproducing any form of vibration that I was *able* to transmit. I remember speaking of this to different ones about this time; I may have mentioned this before the 1st of April, 1874, or it may have been a little while after. My impression is that I first mentioned it before. My conception then of an instrument for transmitting articulate speech was one of a complicated character, having a series of transmitting points adapted to respond to all the tones of the human voice, somewhat similar to the apparatus referred to in my caveat of February 14, 1876."

The description contained in the caveat is as follows:

"I contemplate, however, the use of a series of diaphragms in a common vocalizing chamber, each diaphragm carrying an independent rod and corresponding to a vibration of different rapidity and intensity, in which case contact points mounted on other diaphragms may be employed."

When called upon to explain the construction of the apparatus thus ambigously outlined in his caveat, Gray confesses that it was a general idea, not clearly defined in all its details, and based upon a theory which has since proved to be false. The instrument was never constructed by him.

It is evident that while Gray's caveat may be accepted as a conception of the invention of the telephone, a method and also an apparatus, Gray himself did not fully understand it, and, as stated, was unable to explain the mode of its operation. In other words, even after filing the caveat and before the true secret of the telephone had been made known by the publication of Bell's patent and his lectures and experiments at the Centennial, Gray still adhered to the old idea that articulate speech must be transmitted upon the multiple-telegraph principle, by the use of a series of diaphragms in a common vocalizing chamber, each diaphragm carrying an independent rod and responding to a vibration of different rapidity and intensity; so that the earliest possible date of conception which can be given to Gray is February 11, 1876. But of course this cannot affect Bell's patent, for the reason that the evidence is satisfactory and it is absolutely conceded by Gray that he did not reduce his invention to practice for a long time after the issuance of Bell's patent; that in the mean time, regarding the invention as of trivial importance, he neglected it altogether and turned his attention to other inventions to the exclusion of

this, so that the Examiners-in-Chief were justified in finding that Gray was neither diligent in filing an application in the Office nor was he diligent in reducing to practice, and consequently, under well-settled principles of law, cannot be given the benefit of his date of conception as against another independent inventor.

But Bell is shown to have conceived the invention on the 20th of January, 1876, when he prepared his specification and showed it to others and subsequently filed it in the Office, on the 14th of February, as heretofore stated. There is no doubt that Bell prosecuted his discovery with great diligence, at once filing his application and obtaining the patent at the earliest moment possible.

These facts are not only conclusive and convincing, but the conduct of Gray afterward is equally satisfactory as to the same. His concessions were made at a time when he was vastly interested in making the most thorough examination of the facts before he should concede anything. His omission to file his applications until nearly two years after the date of his caveat, his concessions made in the Patent Office as matter of record in a controversy, and the further fact that when he filed his applications it does not appear that he had changed his belief as to who was the first inventor, but was acting in the interest and under the direction of the parties who had in view a litigation with Bell as to the validity of his patent, all serve to confirm the correctness of the decisions of the Office giving priority to Bell.

So far, therefore, as the present petition of Gray may be said to be a motion for a rehearing of these issues upon the alleged ground of error in law or in fact, or both, in the decisions to be reviewed, it might well be regarded as disposed of here; for Gray proposes no new or additional evidence as to the dates, nature or character of his own invention. What he did as an inventor, the experiments he made, the date of conception, his caveat, applications, etc., remain fully stated, described and disclosed in the evidence already submitted by him. He does not propose to add anything to the evidence upon which the several decisions before the Office have heretofore proceeded; nor does he pretend that the collusion and misapprehension on his part or the supposed misadvice of his counsel, or other matters to be hereinafter considered, prevented him in any manner from giving his testimony, from giving all the facts—the whole truth—with reference to the history of his own efforts and transactions as an inventor. Upon the evidence introduced and considered the decisions were correctly made and the award or priority of invention was justly given to Bell. With his patent construed and sustained as it has been in the courts Bell must upon the record before the Office be held to have been the first to conceive, the first to disclose and by his patent give the invention to the world; the first to reduce the invention to practice, first, constructively by his patent, and actually, later, by the transmission of speech in the early part of 1876, as explained.

But in his petition to reopen the interferences Gray seeks to go farther and affect these decisions in the Office upon the evidence adduced by a direct attack upon the procedure in the Office, and by the introduction of new and additional evidence to establish the alleged fact that Bell was not an independent inventor, but pirated the invenion from him, Gray.

Without presenting all the points *seriatim* or following the petition and argument in their exact order, the several propositions may be stated as follows:

First. As to these issues before any substantial progress had been made in taking the proof in these interferences. The Bell Telephone Company, owning Bell's two patents, had acquired or supposed they had acquired, by assignment all the other patents and inventions supposed to possess any value involved in the interferences, including Gray's; that from thence on the proceedings in the interferences were mainly under the management and control of said company and its associates with the view of reaching such result as they desired, viz., priority to Bell, said company paying counsel on both sides and all other necessary expenses, and the proceedings were therefore collusive and should be disregarded and set aside.

Second. That the concessions of priority made by Gray in favor of Bell were made under incorrect and improper advice of his (Gray's) counsel, who later on in the interference was paid for his services by the Bell Telephone Company combination, acting under the Dowd settlement of November 10, 1879, and was under their influence; and that it was in consequence of this improper advice under these conditions that he declined to appeal from the decision of the Examiner of Interferences as to these issues. Also that these concessions were made and his subsequent course governed by the belief that Bell was in fact an original inventor, had actually filed his application in point of time earlier than Gray's caveat had been filed; whereas he now believes that neither of said conditions existed, but on the contrary Bell had fraudulently secured access to his caveat, purloined his invention, and carried the description therefrom into his application.

Third. Upon the ground of newly-discovered evidence, important and material, which petitioner did not know to have existed in time to produce it before the Office, which new evidence will show that those portions of the Bell specification containing the description of the variable-resistance appliances were not contained in it when originally filed and were not in any of Bell's previous specifications or writings; that he obtained the knowledge and description of them from his fraudulent inspection of Gray's caveat and then fraudulently caused them to be written into his application after it had been filed, and so he, Bell, was not, in respect to them, an original inventor.

Fourth. That the decisions of the Office were erroneous in law and in fact, because, as a matter of fact, Gray's caveat was filed before and not after the filing of Bell's application, and consequently it was error to give Bell the status of a patentee, the rule being in such cases that Bell was to have been regarded as a mere applicant for a patent on an equal footing with Gray.

1.—THE ALLEGED COLLUSION.

Gray alleges that the proceedings in these interferences in the Patent Office were collusive because the Bell Telephone Company, as was supposed, had acquired all the interests involved and was, therefore, able to mould and control the decisions in such form as it saw proper. This proposition, of course, depends upon whether this company had then acquired Gray's inventions. He now claims that it had not, that the inventions then belonged and still belong to him, and that it was merely a matter of supposition at the time that it had acquired his inventions. He does not pretend that in consequence of that belief he was in any manner deterred from presenting all his evidence and receiving all the consideration to which he was entitled, or that he can now add anything to the evidence or present any new consideration as to the origin or date of his invention.

It is rather a peculiar situation in which he finds himself. He is forced to assert that the company had acquired his inventions in order to establish the collusion, and is required then to deny that it had so acquired them in order to find a standing for his petition to vacate the decisions upon the ground of collusion. His counsel cite in support of the proposition the following authorities: Cox *v.* Hardwick. Cases Temp. Hardwick; 237; Earl of Bandon *v.* Betcher, 3 Clark & Finnelly's Reports; Lord *v.* Veazie, 8 How., 251; Cleveland *v.* Chamberlain, 1 Black, 419; Wood Paper Company *v.* Heft, 8 Wall. 333; Gardner *v.* Goodyear Dental Vulcanite Company, 6 Fish. 329; Fletcher *v.* Peck, 6 Cranch, 147.

These decisions settle the proposition as stated by the counsel that courts will not try and adjudge cases in which there is no controversy or where the controversy has been settled by the parties themselves; nor will they try moot questions for the purpose of obtaining decisions affecting injuriously the rights of third parties; but none of them establishes that the courts will vacate or set aside their action where in the proceeding before the court, the court has been fully advised of the situation and relation of the parties and with full knowledge has proceeded and rendered judgment. Nor will the court vacate or set aside such judgment where the interests of third parties are not affected at the instance of the parties to the controversy, unless they have acted promptly and called the attention of the court to the settlement or the fact that there is no controversy as soon as that condition arises.

When these interferences were declared, and up to November 10, 1879, there could have been no collusion, for the reason that during this period the Bell Telephone Company had not acquired Gray's interest, and the contest between that company and the American Speaking Telephone Company and others was being hotly conducted. It is clearly established that the Patent Office was well advised, and all parties understood that the Bell Telephone Company had come to be the owner of most of the inventions involved, and had acquired an interest in that of McDonough (involved in issue G), and that the proceeding before the Office, after the settlement of November 10, 1879, was conducted in accordance with the practice which has existed from time immemorial. It is a matter of common occurrence, that interference proceedings are conducted after the inventions involved have been assigned to the same person or corporation. Counsel are employed to represent the respective inventors, take evidence and conduct the proceedings, and the decision of the Office is given for the purpose of ascertaining which of the inventors was the original and true inventor, within the meaning of the statute, in order that the assignee may obtain a valid patent. This practice has been assailed in argument as being irregular and improper and coming within the condemnation of the courts, as found in the decision just cited, but I do not think the decisions are applicable. In these interference proceedings, the public is interested in seeing that a valid patent issues, and the rules of practice are such as to require the procedure to be conducted to a conclusion. The Office is not always willing to award priority upon a stipulation between the parties, but requires that the award of priority shall be determined either by the record date of the parties, or by a satisfactory showing.

Under the English system a patent may be issued to the assignee of a number of applicants for the same invention, and his patent will be valid, provided either of the assignors was the real inventor. In such a case it cannot be presumed that the public will be injured by a patent issued to the assignee under such circumstances, for the reason that he represents the true inventor, although it may not be know at the time which of the several applicants was the true inventor. But under our system a judicial investigation is required by the statute to enable the Office to ascertain who was the true inventor. This requirement is on behalf of the public, or the third party, as it is sometimes called, for in an interference between a patentee and a later applicant, the public is distinctly interested in not having the monopoly prolonged by the issuance of a second and later patent, unless it be made to appear clearly that the applicant was in fact the original inventor justly entitled to a patent which he could obtain in no other way than by an award of priority. For this reason, as just suggested, the Office will not always receive the concessions of the parties themselves as to priority, but insists upon the evidence being produced; and this is just as essential in cases where both inventions belong to the same assignee as in other cases, for otherwise it would be placed in the power of the assignee to obtain a second patent and thus prolong his monopoly. Besides, the patent if issued for the invention of the wrong assignor would be void, if the fact should be developed.

It is urged by Gray's counsel that instead of having what he terms an apparent contest after the Bell Telephone Company had become practically the owner of the invention, it could have been settled upon the record, and Bell's application having antedated all others he would have received an award of priority, and that the course pursued in this case was due to a purpose on the part of what is called the combination of the Bell Company and its associates to secure a decision of the Office which could be used in courts and elsewhere, and was so used in several suits to support the *primas facies* of the patent and to obtain preliminary injunctions *pendente lite.*

It must be apparent that if the course suggested here had been pursued and an award of priority entered upon the record without the production of evidence, most of which, as already explained, was taken in a hotly-contested controversy, a still stronger objection could have been urged to the award of priority than is now brought against the course which was pursued. The question would have been asked then, why did they take an award upon the record and not pursue the ordinary course of taking testimony and establishing the fact upon an investigation? I can see no force in this objection. It may be true that the parties to these interferences at that time desired to secure a proper decision of the Office in order that they might derive such benefit from it as the law and the practice in the courts entitle them to; but it must be understood that at that time Gray was interested in the combination and was not only assenting to this course, but was promoting it, and it is difficult to see how he now can challenge the course of procedure in the Office upon these grounds, when his relation to it was such as stated. Even it were true that it is bad practice to award priority as was done in this case, after several interests have become vested in a single assignee, and that the practice should be abolished, it should be for future cases and not for the purpose of vacating and setting aside a case already disposed of, and especially not for the purpose of reinstating it for a re-trial.

It is evident that in the present petition Gray does not ask to have the decisions of this Office set aside so as simply to avoid them and leave the matter standing on Bell's patent alone, but for the secondary and more important purpose of having the contest reinstated and a re-trial and re-adjudication. In other words, he asserts that at the time the interferences were heard before the Office his mental condition was such that he believed the Bell Telephone Company with its associates to be the owner of his inventions; that his mental condition in this particular has since changed, and he desires the rehearing in order that it may be retried under the new mental condition. He may still, however, be in error as to the ownership, for the record presents strong evidence that his first belief or opinion was correct, and that the Bell Company is in fact the true and equitable owner of the inventions; and if this be true the supposed "collusion" would exist in the new trial as much as in the original.

As already stated, Gray promoted this interference procedure with full knowledge on his part of the settlement and of the facts which he now asserts constitutes collusion. He was also aware that it was conducted before the Office with full knowledge and consent on its part, and in accordance with its recognized practice with reference to such interferences. If this collusion exists, it existed then, and then was the time for Gray to have prompty moved, after November 10, 1879, to arrest proceedings in the Office, on the ground that to proceed further would be in violation of public policy and contrary to the rules recognized by the courts; but having failed to do this and not only allowed without objection, but promoted the controversy to a final decision, in order that he might succeed if he could and obtain an award of priority on behalf of his assignee, he has seen proper to wait until defeated before raising this question of collusion.

To permit this to be done would enable a party to trifle and experiment with the Office, accept its results if favorable and repudiate them if unfavorable.

But there is no judgment in these interferences which the rule of the courts in cases cited would require to be set aside. Priority was awarded to Bell and patents denied to the other interfering parties, much as a bill is dismissed for want of equity. No execution can issue nor other order be made affecting the rights of third parties injuriously or otherwise. The condition of parties remains precisely as it was before the interferences were declared, and as if nothing whatever had been done. In my judgment no court would interfere with an award of this character, and certainly not for the mere purpose of reinstating the contest.

It must follow that if the rehearing is to be granted at all it must be upon other grounds than the collusion referred to.

(2.) GRAY'S CONCESSIONS.

In his present petition Gray seeks to avoid the effect of his admissions and concessions in favor of Bell's priority, upon the ground that they were the result of misapprehension, improper advice of his counsel, and of fraud practiced by Bell in pirating his invention and deceiving him about the facts. He insists that his admissions have been introduced as part of the evidence sub-

mitted, and have had more or less influence in affecting the judgment of the Examiner of Interferences; that his concession of priority and withdrawal from the contest before the Examiners-in-Chief and his failure to appeal from their decision to the Commissioner were the results of the same continuing influences operating upon his mind and misleading him; that in consequence the decision should be set aside, he should be restored to his original status as a suitor, and should be allowed to retry the issues upon the original evidence and such new evidence as he can produce.

It is undoubtedly true that Gray's admissions were introduced in the evidence submitted, and that they were adverted to by the Examiner of Interferences in his decision. The examiner of interference says:

"In addition to the testimony we have the direct admission of Gray, in lectures, publications and letters to Bell, acknowledging that the latter was the first inventor of the apparatus for transmitting vocal sounds. In a letter to Bell, dated March 5, 1877, Gray says, referring to the matter of transmitting vocal sounds: 'I do not, however, claim even the credit of inventing it, as I do not believe a mere description of an idea that has never been *reduced to practice* in the *strict sense* of that phrase should be dignified with the name of invention.' It is clear, therefore, that Gray cannot be regarded as the inventor of the articulating telephone *per se*, and, recognizing that fact, he seeks to maintain such of his claims as are involved in these interferences upon other experiments and inventions made by him with respect to the transmission of sounds generally; and these will next be considered."

It is also true that the Examiners-in-Chiefrecognized G ray as having withdrawn from the contest as to all of the issues except issue G. They say:

"Gray, as before stated, has withdrawn from the contest as to all but this issue. His case does not rest upon the fact that he is the inventor of the art or even of an articulate transmitter, but upon the proposition, as stated by his counsel, that 'having invented, discovered and reduced to practice prior to the other contestants in this case, an apparatus involving the combination' of the issue, he 'is entitled to a patent for that apparatus with all its functions, incidents and capabilities, whether known at the time or not.'"

Even if the law will permit Gray in consequence of the alleged misapprehension, the improper advice of his counsel, and the alleged fraud of Bell, to be restored to his original status and to have a re-trial, it will do so only when we shall have clearly established these allegations as to the mistake, advice and fraud.

An examination of the decision of the Examiner of Interferences shows clearly that while he adverted to Gray's admissions he was by no means controlled by them. His decision proceeds upon the evidence of Gray and the other parties to the interference as to their several acts and proceedings in inventing, and upon this evidence he finds that Bell was the first inventor. As stated, he gives Gray as the date of his conception, February 11, 1876, the date of the sketch on which his caveat was based, and in my opinion no re-trial of the case will ever change that conclusion. His decision also shows that Bell's application, prepared January 20 and filed February 14, 1876, was regarded as his (Bell's) first conception, antedating Gray, and that Bell diligently prosecuted his application and secured his patent. This settled and still must settle beyond serious question Bell's priority, provided Bell's application and patent disclose the invention. Throughout the entire history of these interferences this has been one of the important questions contested. It was determined by the Examiner of Interferences, not upon any concession by Gray, but upon the decisions of the commissioner and the courts who had placed a construction upon the patent, holding that it did disclose the invention. The same decision in this particular was made by the Examiners-in-Chief. These tribunals did not cite the decisions of the courts for the purpose of ascertaining any date or priority as to Bell's patent, because whatever it disclosed it was certainly prepared on January 20, and filed on February 14, 1876, and was proof of a conception of whatever invention was disclosed by it. The courts held, and all the tribunals of the Patent Office have held, that it disclosed the inventions involved, and consequently priority of invention was awarded to Bell upon these facts. As heretofore stated, this question has since been finally settled by the Supreme Court of the United States in the telephone cases; so that it is palpable and clear that if Gray's admissions, which are found in the evidence, and his concessions, which were made as a matter of record in the interferences, be wholly withdrawn from the case, the conclusion as to the priority remains unaffected thereby.

As to the allegation that his counsel, Mr. Baldwin, gave Gray improper advice or was actuated by any improper influences, it is necessary to notice what the advice was and the circumstances under which Mr. Baldwin was placed with reference to his client. It is to be remembered that the advice to which Gray refers was given long before the interferences were declared and before the relations came into existence which grew up between the Bell Company and Gray and others, arising from the contract of November 10, 1879. It was at a time when no influence is claimed to have been operating upon Mr. Baldwin as an attorney except a proper regard for the interest of his client. Gray says:

"At the Centennial, Mr. Bell exhibited a telephone which transmitted articulate speech. I witnessed the exhibition. He did not use a liquid transmitter on this occasion, but used an instrument very nearly resembling the receiver of my invention. I communicated this fact to my counsel and requested his opinion as to how my case stood in view of said fact, and he informed me that practically my claim was defeated; that Bell's application was filed on the same day as my caveat, and that Bell having made an instrument that successfully transmitted articulate speech, he occupied a better position and would undoubtedly succeed."

Now, as to this advice, which is made the foundation of the charge of Gray, it is proper to say that the position assumed by Mr. Baldwin has been shown to have been correct by every decision in relation to the subject since it was given in the Patent Office and in the courts. As to Mr. Baldwin's subsequent course in the conduct of the case, it appears clearly that he acted diligently; that he kept his client, Gray, constantly advised of everything which was done, and in his subsequent relations with other parties and with the Bell Telephone Company, Gray was fully advised and made no objection whatever to them. Under such circumstances a court would hesitate long before granting a relief upon the allegations now presented by Gray or condoning either the advice or the conduct of his attorneys.

The allegation that Bell had fraudulently obtained access to Gray's caveat and had pirated the invention and was not himself the original inventor is a material one and will be considered further on in connection with the subject of the newly-discovered evidence presented by Gray.

But even conceding that Gray could establish these several allegations, there is a grave question whether he could be restored to his original position and be allowed to re-try and re-controvert these issues. If the matter involved were of such a character as to be purely personal between Bell and Gray and the controversy related to private matters alone, there is no doubt that a rehearing might be granted, but in this case there are, in fact, three parties; the public is a party interested and whose rights are to be protected as well as those of Bell and Gray.

Bell's patent has now been running since March 7, 1876. Gray has seen proper, as already explained, to concede priority to him; has come into the tribunal where the question of priority was being determined judicially, and has entered a plea awarding priority to Bell and withdrawing from the controversy. For a valuable consideration he has allowed other parties, supposing themselves to have become the owners of whatever inventions he had made, to invest largely in the property. He became himself personally interested as a stockholder, an officer, and in other particulars, in a corporation or a combination of corporations dealing with both the Bell property and his own, and inducing the public to become interested in them upon the strength of the decisions in this case and his recognition of Bell's priority. As he himself says, in one of his affidavits, as to these issues, he has acted and conducted himself upon the belief that Bell was the first inventor, and that the Bell Telephone Company was the owner of his (Gray's) inventions which they were regarding and inducing the public to regard as invalid and subservient to the Bell inventions. While receiving consideration for his supposed transfer of his inventions he has for several years regarded the matter as settled and disposed of, and until the filing of his present petition, which proceeds upon the assertion that he has obtained new and additional information, he has acted like one who has completely abandoned the invention. It is not necessary to a dispo-

sition of this petition to hold that Gray has actually abandoned these inventions to the public, if they do not belong to Bell, but I have little doubt that his conduct establishes such an abandonment.

The course pursued by Gray in disclaiming the invention, asserting and publicly indorsing Bell as the inventor, and for these reasons entering, before the Examiner of Interferences in October, 1881, his formal withdrawal from the contest, was with full knowledge that the invention then had been in public use for over three years, and that private enterprise throughout the country was investing vast sums of money in the promotion and introduction of the invention. While it is true he still asserted, both in the Patent Office and in the courts, his claim for invention of the receiver (issue G), yet as to the art or method and the transmitter as involved in these issues he made no move to avoid his disclaimer or reassert his inchoate right as inventor until he filed this petition, December 30, 1886, more than five years after his disclaimer, during all which period the public use contained and increased. Now, whether the invention belongs to the Bell Company as assignee of Bell or of Gray, regardless as to which of the two was the real inventor, the invention had gone into public use and innumerable persons had invested in it. Gray was a party to and had encouraged its public use with a disclaimer on his part. It is difficult to conceive much stronger evidence of abandonment on his part. (Pennock *v.* Dialogue, 4 Wash. 538; Kendall *v.* Windsor, 2 How. 322; Am. H. & L. S. Co., *v.* Tool Co., 1 Holmes, 503.) It is settled that abandonment may be after application is filed or patent issued (Bell *v.* Daniels, 1 Bond, 212); and after abandonment the inventor's right is as much beyond recall as when two years' public use intervene before application is filed. He cannot regain his inchoate rights or be restored thereto upon the ground that he was misled or deceived by fraud, etc. (Mellius *v.* Silsbee, 4 Mason, 108; Bowles *v.* Mason, 2 Am. L. T. R. (U. S.) 106; Jones *v.* Sewell, 3 Cliff. 563; Bell *v.* Daniels, 1 Bond. 212.)

Without absolutely holding that Gray has abandoned the invention there are considerations which are quite as fatal to his petition. It is evident that the public has a direct and immediate interest in the further prosecution of Gray's application for a patent. If the award of priority heretofore given to Bell can be vacated and set aside it should only be done upon a showing of merits that would entitle Gray to an award of priority and to a patent. Such a patent would run for a period of seventeen years from the date of its issuance and would dominate and control the method and all the devices relating to the telephone for another period of seventeen years. Its effect would be to subject the public to a renewed monopoly,—in all nearly, if not quite, thirty-four years. Such result is in such contravention of the spirit of the statute and so unnatural a consequence, in view of the liberal provisions of the patent system, that it cannot be tolerated, except where the inflexible rules of law and justice compel it. Before an inventor can demand such a result or a patent that would bring about such consequences, he must show himself not only absolutely entitled, but that he has been diligent and persistent in the prosecution of his rights, and that the failure to sooner secure them has been unavoidable and not due to his own mistakes, laches or failure.

It scarcely needs comment or requires suggestion to show that Gray does not bring himself within the requisite conditions for such relief.

If, in addition to the foregoing considerations, there shall be added the further fact that the Bell Telephone Company acquired the equitable ownership of Gray's invention, under the settlement of November 10, 1879, and the transactions prior thereto, and that a patent to Gray would at once inure to that company and enable it or a new combination in this manner to prolong for another full statutory period its monopoly of the invention, there would appear conclusive reasons for refusing the present petition. There is not the slightest evidence before me of the existence of collusion between the Bell Company and Gray and his present associates by which such a result is sought after; but unless the rights of the public shall be strictly guarded and the principles of law properly enforced, such combinations could easily be made and could successfully and unduly extend their monopolies. It is to prevent such consequences that, in many cases, the Office is unwilling to award priority in interference proceedings upon stipulation of parties.

The state of the title as to Gray's invention will be considered further on.

(3.) THE NEWLY DISCOVERED EVIDENCE: BELL'S PIRACY OF GRAY'S INVENTION.

The proposition to be established is that on the 14th of February, 1876, when Gray's caveat and Bell's application were filed, the latter contained no reference to the variable-resistance method (issues B and C), and claim 4 was not in it; that through improper and fraudulent influences of Bell's attorneys at Washington with the examiner in charge of the subject the former were permitted to see the caveat, and thereupon surreptitiously and fraudulently withdrew Bell's specification, rewrote it, incorporating the portion now found relating to the variable resistance and the new claim 4, and substituted the amended and unverified specification for the old. This, if done at all, must have been done before the 19th of February, for the official letter of that date, addressed to both Gray and Bell advising them of the interfering matter, shows conclusively that the suspected matter of the specification was in it at that date.

There is no claim or pretence that Bell received his ideas from Gray in any other way or by any other means than by this alleged fraud of stealing them from the caveat. Indeed the charge does not connect Bell personally with the matter, for it is conclusively shown that Bell was not at Washington during the period between February 14 and February 19, 1876, nor was he in any manner cognizant of the alleged alteration at the time. The theory presented makes it necessary that the fraudulent alteration should have been made by Bell's attorneys at Washington upon their own responsibility and without the authority or consent of their client.

The evidence of this alleged fraud is the "newly-discovered" evidence relied upon by Gray as one of the grounds for setting aside the award of priority in these interferences. It consists of certain evidence—the testimony of Bell himself taken in the People's case, so-called.

In March, 1876, Bell had written Gray: "My specification had been prepared months before it was filed and a copy had been taken to England by a friend." This was George Brown, of Toronto, whom Bell had interested in his inventions in the fall of 1875. In his testimony in the Dowd case Bell had produced the original rough draft of the specification in seven sheets. He testified that he began to work upon the specification in September, 1875, in Canada. He had searched for other drafts of his specification made in the course of preparing his application, but was unable to find them. This was in July, 1879, when he was giving his deposition. He says the seven sheets of the original draft then produced do not read successively, and were

"the mere remains of my first attempt to put into correct language the ideas embodied in my specification. Some passages are written in pencil, others in ink, and many of them are so disfigured by the corrections, etc., that it is difficult in some cases now to read them."

He further says these original drafts are by no means all he made in preparing the specification for his application. He also states that he had concluded arrangements with Mr. George Brown to have the specification filed simultaneously in England and the United States, and the application was not filed here until February 14, 1876, because he was waiting for a cablegram from England. While he does not specifically state that he gave Brown a copy of his specification, his testimony inferentially makes it clear that he did, for he produces a sketch which he placed in Brown's hands before the latter went to England which was handed back to Bell in 1878. But in the cross examination Bell was not asked to produce that copy which he gave Mr. George Brown, nor to state its contents, or whether it contained anything relating to the variable resistance. The original first draft then produced did not contain any reference to it, and as this was one of the import-

ant facts involved the most natural inquiry would have been to ask Bell about it.

When the newly-discovered evidence now relied upon comes to be considered, there can be no doubt that, had he been asked by Gray, or anyone in the Dowd suit, Bell would have replied that the George Brown copy of the specification did not contain claim 4, or any reference to the variable resistance, and would have given substantially the same statement now relied upon, though he might not at that time have been able to produce the copy.

The evidence in the Dowd case was closed in September, 1879.

In the case of The People's Telephone Company *v.* The American Bell Telephone Company, Mr. Bell aga in testified at great length. His deposition was taken in March, 1883, pending the decision of the Examiner of Interferences, whose decision was announced in July following. While Gray was not a party to this suit, he must have been interested in it and cognizant of the progress made therein.

At this time Bell was able to produce some additional memoranda, letters, etc., and among other things he produced the George Brown copy of Bell's specification which the latter had taken to England with the view of taking out the English patent, and which he had returned to Bell in 1878. It is this evidence of Bell relating to the George Brown copy which is relied upon as being new, important and relevant. It is stated substantially as follows:

In his decision (p. 320) the Examiner of Interferences calls attention to

"certain suspicious circumstances attending the production and development by Bell of the liquid-resistance or water telephone, that demand attention. There is an entire and absolute absence of evidence tending to prove that at the time or prior to the filing of his application of February 14, 1876, he had conceived, disclosed, experimented upon or tested, or even contemplated so doing, any form or system of articulating telephones other than magneto, as disclosed in fig 7 of his patent, with the single possible exception of the abandoned and discarded idea of the vibrating wire."

In September, 1875, while in Canada, Bell began the preparation of the specification for his patent and continued it in Boston during the early part of October following. In the Dowd case he produced some rough drafts of his earliest efforts, which were mere fragmentary remains of his first attempt. His specification was prepared subsequently for Mr. Hubbard to take to Washington and have examined by their attorney, Pollok. In January, 1876, Hubbard wrote to Bell:

"I have been over your specification with Mr. Pollok. He is very much pleased with it, and says he does not think it will require any alteration."

A fair copy of the specification was received from Mr. Pollok on the nineteenth or twentieth day of January, 1876, as shown by a letter addressed to Mr. Bell, under date of January 18, 1876:

In his preliminary statement Bell says:

"I completed the specification for my American patent early in January, and sent it to Mr. Hubbard in Washington to be examined by Mr. Pollok. I am not able to fix the date when I sent it: but on the 18th of January I received a letter from Mr. Hubbard expressing his satisfaction with it, and it must have been returned to me then or immediately after, as I made oath to it in Boston on the 20th of January, 1876, and sent it back to Mr. Hubbard. The reason why it was not filed immediately was that it was deemed important that I should meet Mr Pollok and go over it with care. We met in New York shortly after and spent a day, January 25, 1876, in considering the specification. No change whatever was made in it, and Mr. Pollok took it back with him and filed it in the Patent Office."

Hubbard testifies:

"I saw the specification of the speaking telephone in October, 1875. I believe it was substantially like the one for which the letters patent were issued, though several changes were made in it subsequent to my first seeing it. I believe I took it with me to Washington on the 1st of December, 1875. I showed it to Mr. Pollok, brought it back with me on leaving Washington, December 14 or 15: then took it with me on my return to Washington, which was, I think, on the 10th of January, 1876; showed it again to Mr. Pollok, then I returned it to Mr. Bell for his signature and oath."

On the 28th of September, 1875, Bell wrote from Toronto to Hubbard that he was about arranging with his friend, Hon. George Brown, ex-premier of Canada, to become interested in the subject of the invention. On the 29th of December, 1875, a contract was made between Bell, George Brown and J. Gordon Brown, in Toronto, by which Bell agreed to assign them a fourth interest in all his "patents and inventions that are now or may be hereafter taken out in any other parts of the world, except the United States of America," and on the same day received a memorandum from the Browns agreeing to pay him, Bell, twenty-five dollars apiece per month while perfecting his inventions in telegraphy and preparing the necessary specifications for taking out patents under their agreement of that date.

Hubbard also testifies:

"I met Mr. Bell in New York about January 25, at his request to meet Mr George Brown, of Toronto. We met Mr. Brown, and he agreed to take out letters patent in Great Britain. Mr. Bell gave me his copy of the specification, which I was to take under a promise which he exacted from me that it should not be filed at Washington until Mr. Brown should have filed it in England. He did not hear from Mr. Brown as he expected and finally wrote to me that if he did not hear by a certain day that I might file it. I strenuously objected to the least delay, but it was of no avail, as he wished to have it taken out in his native country, that he might there have the benefit of what he believed to be a great invention.

All the foregoing testimony was given in the Dowd case; now follows the "new testimony," which is found in the People's record:

"*Int.* 567. About when did Mr. George Brown go to England?

"*Ans.* About the last week in January, 1876.

"*Int.* 568. Did he take with him a specification furnished by you, corresponding to the specification of your patent of March 7, 1876?

"*Ans.* He did.

"*Int.* 569. Please look at the paper now shown you, and state whether it is the specification which you furnished to Mr. George Brown?

"*Ans.* It is.

[*Complainant's counsel puts a copy of the paper in evidence to be marked "Complainant's Exhibit George Brown Specification."*]

"*Int.* 570. How long before Mr. George Brown sailed for England did you deliver this paper to him?

"*Ans.* I only know that it was handed to him between the date of the agreement, December 29, 1875, and the time he sailed, the latter part of January, 1876.

"*Int.* 571. When was this paper written?

"*Ans.* In October, 1875.

"*Int.* 572. I observe that it is headed 'United States Patent Office,' from which I infer that this particular paper was originally prepared for your American specification and not for the purpose of being handed to Mr. George Brown; what is the fact about that?

"*Ans.* Certainly, that is the fact.

"*Int.* 573. Did you at or about the time when you handed this paper to Mr. George Brown also give to him descriptions of your other electrical inventions patented and unpatented?

"*Ans.* Yes.

"*Int.* 576. In the Exhibit George Brown specification there are some alterations made by drawing a pen through words or phrases, and interlining others in place of them; what is your recollection as to when these changes were made?

"*Ans.* I have not any clear recollection of the time when these changes were made, excepting that they were made before the specification was given to Mr. Brown.

MARCH 12, 1883.

"*Int.* 585. You have told me this morning that you wanted to make some addition to your answer to Int. 571. Please do so.

"*Ans.* Yes. I desire to state that, though from the language used in this paper I know that it is a copy of the specification as I wrote it in October, 1875, I cannot be perfectly certain that the copy was itself made in October, 1875, although it is my belief that it was. It was made as a fair copy, not in my handwriting. The interlineations and corrections are in my handwriting.

"*Int.* 586. I observe that the fifteen sheets of which it is composed are numbered consecutively, and each of them bears at the top the initials 'G. B.'; are those initials Mr. George Brown's handwriting?

"*Ans.* They are; I saw him write them.

"*Int.* 587. The last sheet, which happens to be the sheet of drawings, contains on the back this indorsement: 'These papers were received by me from Prof. Alex. G. Bell in the winter of 1875-6, shortly before I left for England. I can fix the exact date by reference to my books and papers, but have not them at hand now. George Brown, Toronto, 12 November, 1878.' In whose handwriting is that?

"*Ans.* In the handwriting of Mr. George Brown. I saw him write it.

"*Cross-Int.* 621. On the papers which you gave to George Brown, preparatory to his going to England, I find indorsed the words, 'November 12, 1878'; how happened that?

"*Ans.* I had just returned from Europe at that time, and understanding from Mr. Watson, who met me at Quebec, that interferences were arising in the Patent Office, I thought it might be important to obtain from Mr. Brown whatever papers he might have. We therefore called on Mr. Brown in Toronto, on the 12th of November, and at my request Mr. Brown indorsed the papers and gave them to Mr. Watson."

The argument which is founded upon this new evidence naturally connects itself with the history of Gray's caveat, and insists that the procedure in the Patent Office in changing its practice with reference to the dates on which caveats are filed, and holding that Gray's caveat had not been filed prior to Bell's application,

the failure to declare an interference and hold Bell's application until Gray could file one, the speed with which Bell obtained his patent, and the circumstances disclosed by this evidence in connection with the evidence in the Dowd suit, establish the fact that when Bell's application was filed it did not contain claim 4 or any reference to the variable-resistance matter.

It is insisted by Gray's counsel that in pursuance of the contract made by Bell with Brown, December 29, 1875, in order to obtain patents in England, Bell handed him after December 29, 1875, a copy of the specification which had been prepared to take to England to be used there; that Brown met Bell, Pollok and Hubbard on the 25th of January, 1876, in New York, when he agreed to take out a patent in England. This was done to have the applications filed simultaneously in England and in the United States, the intention being that Bell should arrange to have both filed simultaneously; and that as George Brown sailed for England the last week in January, he must have left after January 25 and before February 1, 1876. It is further urged that Brown filed no application for a patent in England upon the specification he took there, and it was not until the 9th of December, 1876, that the application was made for a patent in England by Bell, in the provisional specification of which appears the description of a liquid transmitting device.

It is concluded by counsel:

"There can be no doubt, in view of this evidence, that the specification which George Brown took to England in January, after the 25th, 1876, was a copy of the specification sworn to by Bell five days before, on the 20th of January of the same year; but this copy taken by Brown *does not contain the portion of the description regarding the variable-resistance appliances found in the present Bell specification in the Patent Office*. It is impossible to believe that if Bell had thought of these variable-resistance devices prior to Brown's going to Europe, he would have omitted to describe them in the specification which Brown took there to file simultaneously with the application in this country."

I think the argument has been fairly stated and as strongly as made by the counsel, and it will be seen that the entire force of the argument resides in the proposition that the Brown specification, which had been given to him by Bell, was the exact copy of the specification sworn to Bell on January 20, and filed in the Patent Office February 14, 1876.

The George Brown specification is headed "United States Patent Office," and Bell says it was prepared for the American specification, which shows quite conclusively it was prepared before he had made any definite arrangement with Brown. Bell testifies that the paper was written in October, 1875; that is, that it is a copy of a specification written by him in October, 1875, and while not certain that it was made (as a copy) in October, it is his belief that it was. Bell further testifies that the original drafts produced in the Dowd suit were by no means all the specifications he prepared between September, 1875, and January 20, 1876; so that it is reasonably established that Bell was industriously at work preparing, amending, rewriting, and improving his specifications between those dates. It is clear of course that the American specification was completed about January 10, 1876, and remained unchanged until filed February 14.

Now the argument for Gray concedes that Bell had invented the magneto undulatory telephone, and described it both in the original drafts and in the George Brown specification; for it clearly appears in both. In the latter Bell distinctly asserts that he does not limit himself to any particular mode of producing the electrical undulations. and attempts to broaden his description so as to include others. He says in the George Brown specification:

"There are *many other ways* of producing undulatory currents of electricity, but all of them depend for effect upon the vibration or motion of bodies capable of inductive action. A few of the methods that may be employed I shall here specify,"

He then adds four illustrations of known methods, but does not include the variable resistance. In the statement that all of them depend upon inductive action he was mistaken, for the liquid-resistance mode was then known.

Whether Mr. Bell was sufficiently skilled in patent law to know the importance of embracing in his specification all known methods of producing variations or undulations in the electric current is not shown, but the above quotation indicates that he was, and that he was attempting to specify them. Certainly any one possessing such knowledge would have embraced all *known* methods. The situation was this: Bell had made the discovery, which depended upon the vibratory or undulatory current. This called to its aid and dominated all known methods of producing those undulations. Any one would properly desire to introduce into his specification and cover all the methods. In preparing his specification in October, 1875, Bell evidently tried to do this, and incorporated four methods, but omitted the fifth, the liquid resistance method. But this was a well-known method, just as well known as the others. Bell invented no methods of producing variations in the current; he only applied what were already known. The liquid-resistance mode was then as well known as the other methods which Bell described in his George Brown specification. It required no invention to apply it, for the use of diaphragm was then so well known that the attachment of a diaphragm to the wire which was to be vibrated in the liquid could have been made by any ordinary mechanic. It was fully suggested in the *lover's telegraph*, where the vibrations of the diaphragm operated longitudinally on the string. Why, then, did not Bell introduce this liquid-resistance method into his October specification? Possibly because at that date he may not have known of the liquid-resistance method, or, if he did, it did not occur to him at the time. Where then, could Bell learn that? Is there no source from which he could have derived this knowledge prior to filing his application, unless he acquired it through Gray's caveat? Must he have thus acquired it from Gray's caveat and then have fraudulently incorporated it in his application? Assuredly not. The information existed in books, and was matter of common knowledge. It could be obtained from associates, those with whom he conversed. It is probable that Bell possessed the knowledge previously, but it did not occur to him when preparing the first drafts of his specification; the magneto undulatory mode, depending upon induction, through which the invention had been made, being at that time uppermost in his mind.

A comparison of the original draft, the George Brown draft, with the final specification shows that they present internal evidence of progression toward completeness, and that they were not written at the same time, nor can either be a copy of the other.

A complete *alibi* is shown for Bell. If the fraudulent interpolation was made, it must have been made between the 15th and 19th of February by his attorneys without his knowledge or consent. There is not a scintilla of evidence that they had any possible knowledge of the existence of the caveat until after the 19th of February. The Bell specification is word for word the same as his patent. I have personally examined the specification, and find that it is written upon both sides of the paper in a clear fair hand, so continuously from page to page that if any such change or alteration was made, the entire specification must have been abstracted and a new one restored in place of it.

It is incredible that attorneys of intelligence and standing would, without their client's knowledge, change a specification which had been prepared with such unusual care, and thus imperil his rights in such a novel and valuable invention. They could not know that the additional matter could be properly added, and consequently the act might be condemned by their client, not only as prejudicial, but as an infamous fraud. If the alteration was made by the attorneys who had stolen the idea from the caveat, it would have introduced the identical invention found there, for they were neither electricians nor experts; but the invention introduced was a different one, and shows that whoever wrote the passage understood thoroughly the secret of the telephone, which Gray did not. Gray used a liquid of *high* resistance. This suspected passage in Bell's specification called for a liquid of *low* resistance. Bell had been in pursuit of the delicate sound waves that constitute *quality*. This Gray did not understand when he prepared his caveat, for, as shown heretofore, Gray was unable to explain the operation and still adhered to the multiple-tone idea. In other words, the suspected passage shows a full appreciation of the invention which is not found in the caveat, and which neither Gray nor the attorneys of Bell possessed sufficiently to have prepared it.

The charge in the practice as to caveats which held a day *punctum temporis*, was made by the Commissioner upon consideration, and not by the suspected examiner, whose action in the matter had been adverse to Bell. There can be no question that Commissioner Spear's action was correct. (Louisville *v.* The Bank, 104 U. S. 469.) The fact that the Bell application was filed in the Office earlier in the day than the Gray caveat was determined by an investigation instituted by the Commissioner at the time when it was susceptible of investigation. Both Bell's and Gray's attorneys knew just when the respective papers came into the Office. Attèntion has already been called to the fact that when the commissioner withdrew his notices as to the caveat, Gray could have had an investigation, but did not, nor did he arrest the issuance of Bell's patent when he might have done so by filing his own application. But he did neither, and no doubt it was because his attorneys were entirely satisfied that the Bell application preceded the caveat "a couple of hours." Notwithstanding that this subject was urged upon the attention of the Supreme Court in the telephone cases, that court appears to have disposed of it in a single sentence, "Bell's application was filed February 14, 1876, and *afterward*, during the *same day*, Elisha Gray filed a caveat," etc. The order of filing was thus judicially declared, and there is no intimation that having been filed on the "same day," one was not filed earlier than the later, or that the caveat had not been given its proper status in the Patent Office.

The Bell patent issued very promptly. It met with neither anticipating reference nor with interference. It was a new art, for the transmission telegraphically of articulate speech, and so went speedily to patent because it went unchallenged.

In concluding this subject of the alleged fraudulent alteration of Bell's specification, it is proper to observe that this very question, based upon this identical new evidence, was presented to the Supreme Court in Telephone cases, and was fully considered and passed upon. I might have contented myself merely with citing the portions of the opinion relating to it, but I felt it necessary to dwell upon some considerations not mentioned there. One extract from the opinion will be sufficient :

"On the 25th of January, 1876, Bell met Brown, who was then on his way to England, in New York. It is now assumed that the paper which Brown took to England was handed him then, and because the variable-resistance method and the fourth claim were not in that, it is argued that they could not have been in the American specification at that time. But no one has said when the paper was actually handed to Brown. Bell says he cannot tell, but that it must have been after he had made his contract with Brown on the 29th of December. As the American specification was signed and sworn to five days before the interview with Brown on the 25th of January, and the paper of Brown differs from it in so many particulars besides that now in question, it would seem to be clear that the paper was a copy of some former draft which Bell had made—possibly one taken to Canada in December, and not of that which was perfected afterwards. As the specification which had been prepared and sworn to was a fair copy, without erasures or interlineations, the fact that the paper handed Brown was not a fair copy would imply that it was not intended to be a exact transcript of the other. At any rate, the bare fact that the difference exists under such circumstances is not sufficient to brand Bell and his attorneys and the officers of the Patent Office with that infamy which the made charges against them imply. We, therefore, have no hesitation in rejecting the argument. The variable-resistance method is introduced only as showing another mode of creating electrical undulations. That Bell had had his mind upon the effect of such a method is conclusively established by a letter which he addressed to Mr. Hubbard on the 4th of May, 1875, and which is found in the Dowd record, introduced into the Overland case by stipulation. Its insertion in his final draft of his specification is another proof of the care with which his work had been done."

I am of opinion that this so-called new evidence is really not such. It does not appear but that all the facts sought to be established by it, viz., that the George Brown specification did not contain the variable-resistance clause, could have been ascertained by asking for it in the Dowd deposition. Neither is it shown that by the use of ordinary diligence Gray could not have discovered this evidence in the People's case years before he did. The difficulty is that he has been acting under the belief that he did not own the inventions, and that Bell was the prior inventor and has allowed years of inaction to follow. Under these circumstances he cannot allege diligence or be excused for negligence. Especially will not a court excuse his negligence and delay when the causes assigned are not established, and it accepts his former opinion as to ownership and priority to have been correct.

But even if satisfied that the evidence was newly discovered and that Gray could not have earlier discovered it by the exercise of diligence, it would still be unavailing, for the reason that, giving it all the force and effect asked for it, it could not change the result or throw any doubt upon the correctness of the former decision.

As to issue C, it is insisted by Gray that the decision in the interferences was erroneous because Bell does not show or describe a liquid transmitter in his patent, and that consequently there should not have been an interference nor an award of priority to Bell. Some justification for the suggestion may be found in the decision of the Examiner of Interferences, who says: "While no such instruments are found described in Bell's patent, his proof as to Exhibit 41, its description, use and exhibition, are considered as amply sufficient to defeat the claims of Gray and Edison, founded upon the facts appearing in the record, at the same time anticipating Richmond's record date of August 24, 1877."

But evidently this view is a misapprehension of what the Examiner of Interferences means. He does not mean that a liquid transmitter is not shown, but that its specific contruction was not shown in Bell's patent. As heretofore stated by me, the liquid-resistance method and means of applying it by moving the wire by hand or otherwise were well known, as was also the use of a membrane or diaphragm, so that any one skilled in the art would know from Bell's patent how to construct such a transmitter. It was therefore deemed to be shown in that patent. The examiner declaring the interference must have so held, otherwise he would not have made Bell a party to issue C. Not only this, but Gray made no motion to dissolve the interference, and I have no doubt as to the correctness of the action of the Office in either declaring or deciding the issue. What has been said about issues A and B is conclusive as to this.

GRAY'S TITLE.

The Commissioner of Patents has no equitable jurisdiction over the rights of parties claiming under assignments and grants of inventions and patents. He cannot set aside or vacate such instruments, nor can he recognize equitable rights growing out of transactions between inventors and applicants and other parties. While he is authorized to recognize formal legal assignments, and, when they have been filed in the Patent Office before patent issues, may give the assignee control of the management and prosecution of an application and direct the patent to issue in the name of the assignee, yet he cannot recognize equitable rights under executory or other equitable contracts. (*Ex-parte* Edison, C. D. 1875, 42.) But when a party to an interference which has been determined adversely to him asks a rehearing and bases such request upon the allegation that during the trial he was laboring under the supposition that he had parted with the ownership of his inventions, and that in consequence, although he remained a party, was active in securing and giving testimony, the parties to whom he supposed he had transferred were the actual managers of the case; that in consequence—"I had no counsel, I was not a litigant. The whole apparent controversy was, as I now believe, collusive, carried on with an appearance of an array of opposing counsel,"—the question of ownership is made material, and it is competent for the Commissioner to examine it in order to know how to exercise his discretion intelligently. A party cannot make the question of ownership or non-ownership a material ground of the relief sought and at the same time deny the power of the tribunal to consider and pass upon it.

It is unnecessary to again refer at length to the transaction between Gray and White and the American Speaking Telephone Company and its associates, resulting in the settlement of November 10, 1879. It is evident that that agreement and the transfer of telephone inventions were made under the belief that it included Gray's inventions, and but for such belief it would not have been made. Gray so understood the agreement, and was a beneficiary under it. The American Speaking Telephone Company had previously put out large numbers of Gray's telephones as its own property. In the settlement of November 10, 1879, it was expressly stipulated that the inventions of Gray

became the property of the Bell Company. That all this was done with the full knowledge of Gray is not controverted. With this knowledge, and acting under this belief, Gray has allowed seven years to pass, knowing that third parties were also acting in the same belief and making investments upon the strength of the transactions, and that the interests of the general public were directly involved. If Gray can now repudiate these transactions and assert his ownership, it would constitute *pro tanto* a rescission of the agreement of November 10, 1879, though it would be totally impossible to restore any of the parties to their original situation.

Under these circumstances the authorities relied upon as to the estoppel seem conclusive. The Bell Company is certainly the equitable if not the legal owner of Gray's telephone inventions.

Bronson's Exe'r *v.* Chappell, 12 Wall. 681.
Morgan *v.* R. R. Co., 96 U. S. 716.
Bank of U. S. *v.* Lee, 13 Pet. 107.
Dickerson *v.* Colgrove, 100 U. S. 578.
Baker *v.* Humphrey, 101 U. S. 494.
Close *v.* Glenwood Cemetery, 107 U. S. 466.

It follows, therefore, that Gray was not mistaken in his original opinion that the Bell Company had become the owner of his inventions, also that his original belief that Bell was the first original independent inventor and had not pirated any invention from his caveat was also correct, and that all the alleged grounds for reopening these interferences and granting a new trial must fail.

ISSUE G.

"A telephonic receiver consisting of the combination in an electric circuit of a magnet and a diaphragm supported and arranged in close proximity thereto, whereby sounds thrown upon the line may be reproduced accurately as to pitch and quality."

This issue relates to the receiver. All that has been said about the title of Gray's inventions involved in the other issues is equally pertinent here ; that the conclusion is much strengthened by transactions not yet referred to.

Gray took out patent No. 165,095 on July 27, 1874. This covered what is commonly called the blacking-box receiver. It has been formally transferred with other of Gray's inventions by mesne assignments, until it came to belong to the Harmonic Company. It was reissued to the latter company. In 1880 the Harmonic Company assigned it to the American Speaking Telephone Company, so far as it related to speaking telephones, but not including its use for harmonic telegraphic purposes. This patent, subject to this limitation, subsequently went to the Bell Company, under the contract of November 10, 1879. Gray obtained reissues of the patent, with claims of which this is one :

"The diaphragm or disk of metal capable of responding to all kinds of tones vibrating in unison with the electro-magnet included in the electric circuit, substantially as set forth."

In his testimony in the Dowd case and in his preliminary statement in the interferences Gray repeatedly stated that he had made the inventions embraced in issues G, I, C and E in the year 1874, and that they were covered in his patent No. 166,095, which, as already explained, has been assigned, then reissued to the Harmonic Company, and then, as to the use of said inventions as telephones, transferred to the Bell Company. Thus, according to Gray's description of the inventions and his claim for the same, there is a technical formal transfer of them and he is not the owner of them. His patent No. 166,095, and the reissue, would bar his present claim, and even though he could take out a patent it would at once become the property of the Bell Company.

While it is true that patent No. 166,095 and the reissue of the same cover a receiver, "the diaphragm or disk capable of responding to all kinds of tones vibrating in unison with the electro-magnet," etc., yet the present contention of Gray, in issue G, is that he had invented a receiver that would thus respond to *tones*, and he believed and also expressed the opinion that such a receiver was capable of responding to quality and of reproducing articulate speech, if a transmitter could be found; and that therefore his *tone* receiver was a *quality* receiver, the latter capacity of responding to quality arising only from a new or additional use of which the receiver was originally and at all times capable.

It is clear that if this be true, still the invention, whatever it was and however capable, has been assigned, and as a telephone receiver is now the property of the Bell Telephone Company.

The argument urged with so much force by Gray, that after one of the parties has acquired all the interests in the controversy there should be no further contest, is certainly applicable here where the objection is presented and urged. Especially is it true that under such circumstances a defeated party who has parted with all his interest cannot be allowed to reopen an adjudication in order to retry a matter in which he can have no interest. The discretion of the Commissioner cannot properly be called in aid of a request to reopen and re-try these interferences simply to gratify the personal pride or reputation of one of the parties. If the title to Gray's invention is vested in the Bell Company, and that company is content with the adjudication, no one else can properly complain.

Referring now to the merits of this issue G, its proper construction must be determined. As heretofore shown in the statement of the facts, and extracts from the decisions, the Examiner of Interferences held the issue to mean—

"a receiver containing an electro-magnet and a diaphragm supported and arranged in close proximity thereto, and adapted to respond to variations in the electric current passing through the coils of the magnet, when used in connection or combination with a transmitter adapted to create sound-producing fluctuations in the electric current, *whether said electrical variations, waves, pulsations, or undulations represent or are derived from sound waves or mechanical vibrations.*"

In other words, he held in effect that the issue covered a receiver which was capable of responding to and reproducing the tones in pitch of sounds, possessing the capability, when operated on by a proper transmitter, of responding to and reproducing the more delicate variations that constitute quality; that it was merely a new use when a receiver which had responded to a transmitter of tone or pitch was placed in connection or combination with a transmitter capable of transmitting quality or articulate speech. I have already called attention to the fact that the potential possibility of a disk held in close proximity to an electro-magnet was old. It existed in a rudimentary state in the Morse telegraph, and has not only been described in such publications as those of Bourseul and others, but it was long known that the armature or diaphragm would respond to the increased or decreased energy of the electro-magnet in connection with the electric circuit. Not only this, but it was believed and so expressed by scientific men and published in publications, that if the circuit could be controlled by some proper device or transmitter, articulate speech conld be transmitted and reproduced by the receiving disk. But between these speculations and the discoveries which realized them, there lay long regions of invention.

When it is recalled to mind how near Reis came to discovering the telephone,—what a slight apparent line lies between his transmitter and the microphone transmitter of Berliner so near, indeed, that the former sometimes, without the knowledge of its inventor, may have operated on the principle of the microphone and sent across the circuit a stray word or syllable, and, in the light of more recent knowledge, can be adjusted to act as a microphone,—we can appreciate how near men may approach to great discoveries without finding them, and what distances in invention sometimes separate necessities or speculations that are almost contiguous.

If it can be said that there is no invention or patentable difference between a receiver which, by reason of want of skill and knowledge, can only reproduce tones, and one which, by the invention of a proper transmitter, can reproduce quality, and that the new relation or adjustment of the latter is only a new use of the former, then we may go back and say of the former that there is no patentable difference between it and the Morse receiver or that described by Bourseul and others, and that its use as a tone receiver is only a new use : for the old diaphragm placed in close proximity to the electro-magnet possessed all the qualities and potentialities of the Bell or Gray diaphragm ; but between these stages of development there was invention. As well might it be said that the reversing of the magneto receiver and using it as a transmitter was merely a new use of it and disclosed no invention. In my judgment no broad claim for a magneto receiver can be main-

tained. It must be limited to its relation to the transmitter with which it is combined; for between such a combination that will transmit and reproduce pitch alone and one that will do this and also transmit quality or articulate speech, there is great invention. The history of the subject, the vain and failing efforts of scientific and learned men of genius for years, demonstrate this, no less than the philosophical and scientific principles involved.

If, however, issue G, could properly bear the construction, given it by the Examiner of Interferences, it will not avail Gray; for if he were allowed to take dates of invention for a receiver of tone or pitch, so should also the other parties to the interference. Edison and McDonough had made inventions of receivers which would reproduce pitch, and of course their tone receivers possessed the same capabilities as to new uses, quality, etc. It is unnecessary to dwell at any length upon the evidence relating to the efforts of these various parties, as the construction of the issue cannot be maintained and was reversed by the Examiners-in-Chief. It is sufficient to say that it is doubtful if Gray ever conceived the invention prior to his caveat; but admitting that he did, even earlier than Bell or Mc Donough, he never reduced it to practice or gave the public the benefit of it, nor did he prosecute it diligently by efforts to reduce it to practice, or by filing an application. Consequently it is impossible for him, upon his own statement of facts, to overcome Bell's record date.

The Examiner of Interferences awarded priority to McDonough, holding that he had first conceived the invention in May, 1875, and had been diligent in prosecuting it up to the filing of his application, April 10, 1876. This decision was subsequently reversed by the Examiners-in-Chief, who awarded priority to Bell and whose decision was affirmed by Commissioner Butterworth; but this need not be considered further here, as it relates to McDonough's case, between whom and Bell the controversy remains. In any event, Gray cannot succeed in this issue.

The proper construction given the issue by the Examiners-in-Chief and the commissioner does not affect Gray's status with reference to it. If priority could not be awarded to him under the former construction it could not be under the latter, for under the latter, as already shown, his earliest date is that of his caveat, which fails to overcome Bell's record date.

Upon these considerations, Gray's petition to set aside the orders, etc., in the interferences, and open up the case anew, must be denied.

MC DONOUGH'S CASE.

McDonough's application was filed April 10, 1876, for a teleloge, or far speaker. He did not claim to have invented a method of transmitting articulate speech.

"The object of my invention is to provide a *means* for transmitting articulate sounds from one place to another through the medium of electricity, and it consists in the combination with an electrical battery, circuit wires, armature, magnet and circuit-breaker, of a transmitting and receiving membrane or sounding apparatus. . . . My invention also consists in the novel construction of the circuit breaker, as hereinafter more fully described."

His original claims were as follows:

"1. The combination with the battery, circuit wires magnet, armature and circuit-breaker of the transmitting membrane A and receiving membrane F, substantially as and for the purpose specified.

"2. The combination with the plates C C of the circuit-breaker D′, whereby the circuit is alternately opened and closed by the vibrations of the membrane A, substantially as specified.

"3. The combination of the bolt D and adjusting nut E of the circuit-breaker D′, substantially as and for the purpose specified."

April 28, 1876, his claims were rejected upon reference to the "old Reis telephone." His claim to the receiver was rejected upon reference to Bell's patent No. 174,465. March 4, 1878, McDonough amended his specification, adding, among other things:

"The breaking of contact may be rendered more abrupt and the contact rendered more perfect by a drop of water or oil."

He also struck out all the claims, and inserted the following:

"The combination with the membrane A, plates C C, the circuit-breaker D′, of the bolt D and adjusting nut E, *for confining the vibrations* of the membrane againt the circuit-breaker, substantially as specified."

At the date this application was filed the principle of the microphone had not been discovered or applied; but at the tim e this amendment was filed it had been and was known. The change by the amendment whereby the nut E was given what seemed a new function, not originally contemplated, "for *confining* the vibrations of the membrane against the circuit breaker," was regarded by the office as a departure from the original invention and as an attempt to adopt or incorporate the new feature of the microphone.

Accordingly, on March 8, 1878, the Office replied as follows:

"The amended claim filed March 4, it is thought may be allowed. The matter introduced at the end of the specification by this amendment is, however, held to be new matter as it describes modifications nowhere adverted to or shown in the application as originally filed. This matter should consequently be erased."

This claim involved nothing but the peculiar construction of the *circuit-breaker*, and thus left the application without any claim to a receiver or other element in the teleloge or telephone. From that date until the present time no other claim has been presented.

On March 26, 1878, the interferences were declared and notices issued to the parties. Under the practice then and ever since existing, McDonough could not have been put into interference with Bell, and no issue could have been formulated between their inventions, for the reason that McDonough claimed nothing shown or claimed in Bell's patent. He was brought into the interference in consequence of the fact that applicants whose cases were filed later than his (Edison, Gray and others) made claim to elements in the telephone which he showed but did not claim. In other words, when rejected upon reference to Reis and to Bell's patent, McDonough submitted to the rejection and voluntarily eliminated the claims, much as a suitor in court dismisses certain counts in his declaration; but inasmuch as his application still showed a so-called telephone, he was put into interference with Gray and others, so as to compel them to establish that they made their inventions earlier than that shown by McDonough. His position was, therefore, one of obstruction to Gray and other later applicants, but not to Bell, whose application was earliest in the Office. It would seem, therefore, a natural and necessary consequence, inasmuch as there could be no interference between McDonough and Bell alone, that when Gray and the later applicants were defeated and taken out of the interferences, there could be left no interference or contest between the former two. Especially would this seem to be true in view of the fact that McDonough had expressly avoided an interference with Bell by dismissing his claims. Not only did he do this, but afterward, August 20, 1879, he wrote the Office among other things:

"I should like to ask a question, if not improper. Having fully *described* in my application, filed April 10, 1876, a *speaking* telephone, am I not fully concerned in the case of interference A? By answering you will oblige, etc."

He was informed that he could not properly be a party in case A, and that if he thought otherwise he should make proper motion, etc., but he took no action whatever.

McDonough's preliminary statement, filed May 1, 1879, is as follows:

"James W. McDonough, being duly sworn, deposes and says that he is one of the parties to the above-entitled interference; that he conceived the idea of a *telephonic receiver* consisting of the combination in an electric circuit of a magnet, a diaphragm supported and arranged in close proximity thereto, whereby sounds thrown upon the line may be reproduced as to pitch and quality, and also constructed a practical instrument as early as 31st of December, 1867; that subsequently, on the 26th of August, 1871, this deponent made drawings of a speaking telephone embodying his said ideas, and that thereafter, on the thirtieth day of June, 1875, this deponent reduced the same to practice by constructing and operating a speaking telephone, substantially as shown and described in his said application."

It is insisted by McDonough's counsel that this in itself constitutes a claim to a receiver and relieves his case of the difficulty referred to. It will be observed that by the award of priority Gray and all the latter applicants for whom the interferences were declared have been fully disposed of. They are no longer parties, and McDonough is now seeking to reopen the contest as between himself and Bell, when upon his application no such contest could have been originally declared. Nor, under the rules of practice, so long as his present petition stands, can McDonough amend so as to justify such a contest.

I am not prepared to hold that McDonough is barred of this right to petition, in view of the condition of his case. Had he not originally dismissed his claims voluntarily and acquiesced in the rejection at a time when he knew the telephone was going into public use, there probably would have been no question as to his right to amend within a reasonable time so as to claim the receiver; but having voluntarily eliminated his claims, at a time when his alleged receiver was going into public use, and allowed eleven years to elapse without any other effort to amend or file a divisional application including the claim, a very different case is presented. At the date of his preliminary statement the invention had been in public use for over two years, and this, as just stated, with a voluntary cancellation of his claims.

I am not willing to dispose of the petition upon this ground, or hold that, even if McDonough could reopen the interference as to Bell and secure an award of priority, he could not amend; but the situation is suggestive. A patent to McDonough under these circumstances would dominate the entire telephone inventions, as far as now of any commercial value, and it is certainly a serious question whether an applicant who has cancelled his claims and apparently abandoned them, under the circumstances stated, ought to be permitted, after the invention had been introduced and made valuable, to reinstate his claims and receive the benefit of others' enterprise, energy and capital. While it may be said that all through the interferences he has been contending for his receiver, and this was public notice that he had not abandoned it, yet, as already stated, this was done in a controversy with the later applicants.

It is from his application alone that there can be ascertained what an applicant's claims are, and this showed, at least as to Bell and those claiming through him, that McDonough had acquiesced in the references cited in the rejection, Bell being one of them, had cancelled the claims and allowed them to remain so cancelled, and in 1879 had his attention called specifically to the subject of the general interference A, with a statement that he could not be made a party to it.

While it may be that this condition of McDonough's case is not such as to constitute a bar to the relief sought in his petitions, it certainly suggests that his right to the relief should be most convincing before it should be granted.

THE PETITIONS.

The petition signed by counsel as attorneys for the North American Telephone Co., *et al*, is so vague and general that it could not be considered in the civil courts, either as a motion for a rehearing or an assignment of errors. It assigns the following:

First. The interferences were fraudulent and collusive and carried on in the interest of Bell, etc.

This has been fully disposed of in Gray's case, where it more appropriately belongs; McDonough is not in a situation to raise the objection. In interference G there was a contest between himself and the Bell Company as assignee of all the important inventions. It is true that he also had given the Bell Company an executory agreement to transfer his invention to that company, but it was conditional upon securing his patents, so that he still retained the title so as to support his demand for the consideration whenever the condition thereto should be performed. He was a proper and active party. Although much was said in argument about a conspiracy and combination between Bell and others to conduct the interferences in the interest of Bell, the evidence does not support the charges. Indeed, it is impossible to see how McDonough can avail himself of such a charge. It is asserted by implication at least, that the Bell Company undertook or were in some manner under obligation to aid him (McDonough) in the contest to secure his patents; but clearly there is nothing to justify such an idea. In the agreement of November 2, 1880, on on which five thousand dollars was paid McDonough, it is expressly provided:

"This agreement is not to be taken as any manner of admission by either party as to the validity or invalidity of claims made by the respective parties."

This was executed long after the declaration of interferences, after the settlement of the Dowd case, and when McDonough knew well that the respective parties were preparing to establish, if possible, their claims to priority. At that date the Bell Company had become the owner of the important inventions of Edison and others, and had secured a hold upon McDonough by virtue of this contract. However much that company might prefer to secure an award to Bell, it is clear that its status could not be injured by securing as assignee a patent to the person whom the Patent Office should adjudge the prior inventor, for it would then hold both patents. In any event, there is nothing in the statute, the practice, or in reason why the Bell Company as assignee of Edison and other inventors should not contend for such priority as they deemed right and proper; nor is there anything in the relation between McDonough and that company upon which he can found complaint that such course has been pursued by it. He was simply a party to the interference, interested in establishing his own priority. In contested litigations each party necessarily looks after his own case, and cannot complain that the adverse parties do not assist him or do not forego their own interests. Such proceedings are open and public, and before they can be attacked some actual fraud or wrong on the part of the successful party must be shown whereby the right of the losing party has been prejudiced or by which he was prevented from fairly presenting his case.

It is in view of these propositions that McDonough insists that the Dowd record, to which he was not a party, and in which the testimony of witnesses whom he never had opportunity to cross-examine was taken, was stipulated into the interference without his knowledge and consent; but the record shows that this stipulation was made by his own attorney, and that long before the trial of the interferences, and at a time when he could have interposed objection, he was made aware of the fact and was furnished with a copy of the record. At no time did he interpose objection or make any movement to strike the Dowd record out of the case or seek to examine the witnesses. A client is bound by what is done by his attorney in the course of conducting and managing his cause in court. He is presumed to know what is done by his attorney and to authorize it. But here it is shown that McDonough was advised in time to have recovered from the position if there had been anything objectionable or improper in it. It may be, as suggested, that not being a lawyer and relying upon his attorney, he did not personally read and inspect the voluminous record, nor understand what it contained; but this will not avail here. If he is unwilling to be bound by the acts of his attorney, then he must act for himself and cannot plead his own failure as a justification. Especially cannot he do so after trial in support of a motion for a new trial.

As to the difference between the paragraph found in the memorandum of settlement and the formal contract of November 10, 1879, I am not able to perceive that any importance can attach to it. It is immaterial whether in preparing the original draft there was present the idea of submitting the question of interference to the Patent Office or not. If it occurred to the parties afterward, when they came to put the memorandum in formal shape, it was proper to insert it. The interferences had been declared a year before and were pending. It was necessary to dispose of them. Issue G was a seriously-contested matter. The Dowd case was still pending in court. To add to the paragraph the words, "subject to the orders of the courts and the decisions of the Patent Office," was certainly appropriate in view of the situation in which the contracting parties were placed.

The second and third assignments of error relate to the question of priority of invention and the effect of Bell's patent, and will be disposed of hereafter, with the consideration of the merits.

The other petition, signed by McDonough, assigns the following causes for the relief asked, viz., reopening interference G, and granting leave to furnish proofs in regard to operativeness, etc.

First, Error on the part of Commissioner Butterworth in considering certain affidavits of Professors Brackett and Young taken and used in the suit of the Bell Telephone Company *v.* the Overland Telephone Company, but which were not part of the record in the interferences. It appears, however, that these affidavits were read, or parts of them were read, by the respective counsel of McDon-

ough and the Bell Company, without objection from either, so that although not taken regularly or formally in the interference proceeding, they were used therein. Of course, this being so, it cannot be complained of by either party as error.

Second. That the Commissioner decided the interferences with a determination not to decide the issue adversely to Bell. This has been disposed of in the Gray case, where the objection was made that the Commissioner's decision was not a "deliberate" decision. There is nothing to justify the idea or suggestion that the decision was made with any predetermination in either direction.

Third. That having denied, in his decision of January 16, 1885, the motion to reopen the case and remand McDonough's application to the Primary Examiner on the question of operativeness there was error in his final decision in not taking further steps to investigate the operativeness of McDonough's invention; also, in considering the affidavits of Young and Brackett in the Overland case. The decision of Commissioner Montgomery, of March 29, 1887, disposes of this, so far as it relates to operativeness, although I hold that this question inheres in Commissioner Butterworth's final decision and can now be properly urged in McDonough's motion for a rehearing as to that. It will be considered hereinafter, in connection with the merits of the petitions. As to the affidavits of Young and Brackett, that question is disposed of above.

The remaining assignments of error relate to the operativeness of the invention and the merits of McDonough's case, and will be considered under the general subject of

MERITS.

From what has been shown it is clear that McDonough has never claimed to have been the original inventor of the telephone, either the method or the appartus. This appears clearly from his specification in his application and his preliminary statement. In the former he limited his claim to a little device for making and breaking the circuit according to Reis. In the latter he claimed the magneto receiver. He calls himself a mere improver upon Reis's instruments, accepting him as the original inventor. In presenting the petitions under consideration, his counsel, Mr. Hurd, says:

In 1874-5 "there were two classes of applicants before the office; those who recognized Professor Reis as the inventor, and whose efforts and attention were directed exclusively to the development of his instruments and the operation of the methods which he described by which speech might be transmitted. Of these McDonough was probably the most prominent."

So also, Mr. Ingersoll, after stating that the first point in the investigation is whether the evidence absolutely shows that Reis's telephone as invented by him will speak, adds:

"The importance of that is perfectly manifest from the further fact that McDonough claims an improvement on that system, so that the first question is, will the Reis telephone talk? Was it intended to be and is it a speaking telephone?"

It will be remembered that Reis's receiver is what is known as the knitting-needle receiver—a bar of iron within the coil of the circuit wire, and affected by the make and break in the circuit. The only improvement presented by McDonough is to substitute his diaphragm and magnet for this knitting-needle receiver. He had never conceived of the undulatory current or the variable resistance, but accepted and still accepts the make-and-break system of Reis as the foundation of his invention. The Examiner of Interferences, the Examiners-in-Chief and the commissioner have held that articulate speech cannot be transmitted by means of the Reis instruments as made and described by him, and as made and described by McDonough. In other words, it has been and is the settled judgment of the Patent Office that speech cannot be transmitted by any instrument which operates solely by the making and breaking of the circuit according to Reis. This also has been definitely settled with reference to Reis by the Supreme Court of the United States in the Telephone cases.

"But it is needless to quote further from the evidence on this branch of the case. It is not contended that Reis had ever succeeded in actually transmitting speech, but only that his instrument was capable of it if he had known how. He did not know how, and all his experiments in that direction were failures. With the help of Bell's later discoveries in 1875, we now know why he failed. . . .

"We have not had our attention called to a single item of evidence which tends in any way to show that Reis, or any one who wrote about him, had it in his mind that anything else than the intermittent current caused by the opening and closing of the circuit could be used to do what was wanted. No one seems to have thought that there could be another way. All recognized the fact that the 'minor differences in the original vibrations' had not been satisfactorily reproduced, but they attributed it to the imperfect mechanism of the apparatus used, rather than to any fault in the principle on which the operation was made to depend.

"It was left for Bell to discover that the failure was due, not to workmanship, but to the principle which was adopted as the basis of what had to be done. He found that what he called the intermittent current—one caused by alternately opening and closing the circuit—could not be made, under any circumstances, to reproduce the delicate forms of the air vibrations caused by the human voice in articulate speech, but that the true way was to operate on an unbroken current by increasing and diminishing its intensity. This he called a vibratory or undulatory current, not because the current was supposed to actually take that form, but because it expressed with sufficient accuracy his idea of a current which was subjected to gradual changes of intensity exactly analogous to the changes of density in the air occasioned by its vibrations. Such was his discovery, and it was new. Reis never thought of it, and he failed to transmit speech telegraphically. Bell did, and he succeeded. Under such circumstances, it is impossible to hold that what Reis did was an anticipation of the discovery of Bell. To follow Reis is to fail, but to follow Bell is to succeed. The difference between the two is just the difference between failure and success. If Reis had kept on, he might have found out the way to succeed, but he stopped and failed. . . .

"So as to James W. McDonough. We presume that it will not be claimed that he is entitled to more than he asked for in his application for a patent filed April 10, 1876, and there a 'circuit breaker,' so adjusted as to 'break the connection by the vibrations of the membrane,' is made one of the elements of the invention. The Patent Office was clearly right in holding that he had been anticipated by Reis."

The question must now be regarded as finally settled in the Patent Office. The fact that certain patents have been issued to persons *ex-parte* by the Patent Office, whether erroneously or inadvertently, which appear to recognize a different opinion, cannot change a deliberate conclusion thus reached in a contested matter after full consideration.

It must also be recognized as settled, that if an occasional word was ever transmitted by the Reis instrument, the result was due to the fact that the instrument, at the moment it happened, failed to operate in accordance with the principle of its construction; the make and break did not occur; the contact of the electrodes remained, and the instrument secretly and without Reis's knowing the fact operated upon the principle of the microphone, which was not yet discovered. It must also be recognized as settled, that if an instrument constructed according to Reis, and as described by McDonough in his application, can now be made to transmit speech, it must be by means of adjustment of the electrodes, so that it operates, not upon the make-and-break principle as described, but upon that of the microphone, which has been discovered since Reis made his invention.

Now, this distinction is not one of mere theory or speculation, but of principle or knowledge and specific construction of the invention. Under the patent law, invention is not recognized in the mere doing of something new, or the accomplishing of some new result. A new and valuable product may be accidentally discovered and produced, and the discoverer not be able to recall the steps of his process or reproduce the product. There is the first specimen. It is new, concrete, tangible and useful; but there is no invention within the meaning of the patent law. Though the operator has made the product, he does not know how it was made and cannot explain the process to others.

"The accidental effects produced in Daniell's water barometer and in Walther's process for purifying fats and oils preparatory to soap-making are of the same character. They revealed no process for the manufacture of fat acids. If the acids were accidentally and unwittingly produced while the operators were in pursuit of other and different results, without exciting attention, and without its even being known what was done or *how it had been done*, it would be absurd to say that this was an anticipation of Tilghman's discovery."

(Tilghman *v.* Proctor, 102 U. S. 711.)

To constitute invention it is required by the statute that the inventor shall possess knowledge of the very construction of the instrument or means and of its mode of operation, so that he can communicate the same to the world and enable others, pursuing the very directions pointed out, to construct the same instrument

or means, operate it in the manner pointed out, and accomplish the same result. This Reis could not do as to this instrument; for his description of construction and operation was that the electric current must be broken and closed, whereas, to make it transmit speech, the very opposite was required, viz., that the electrodes should remain in contact, so that the microphonic principle of variable resistance could operate. His knowledge was such as would lead the world in directly the opposite direction from that required to produce the desired result, and would show others how not to do it. The true construction and necessary mode of operation remained in the secret arcana of nature until discovered later on. They were not discovered when McDonough filed his application in which, in compliance with the statute, §4888, he attempted—

"a written description of the same (his invention) and of the manner of making, constructing (compounding), and using the same, in such full, clear, concise and exact terms as to enable any person skilled in the art or science to which it appertains or with which it is most nearly connected to make, construct (compound) and use the same; and in case of a machine he shall explain the principle thereof, and the best mode in which he has contemplated applying that principle, so as to distinguish it from other inventions, etc."

What has been said of Reis is equally true of McDonough. He built upon the palpable make-and-break system. The fatal vice of giving the wrong description and directions is in his application, and he can never depart from what was and is now in it. If his teleloge has ever talked or can now be made to transmit speech, it must be changed in its construction and mode of operation so as to become a microphone; or if by the light of later knowledge and experience the makes and breaks, instead of being palpable and of full amplitude, are rendered inappreciable so that its mode of operation is different, the original invention becomes lost in a newer and later one, which must be presented in a new and later application.

McDonough presents a number of affidavits and statements of scientific persons who testify to having been able to make the Reis telephone transmit articulate speech. He has also presented evidence that tends to show that his original instruments did so; but did they do so *in the mode pointed out* by Reis; or by McDonough in his application? These witnesses do not so testify. Most of them simply undertook to make a telephone, constructed like Reis's, talk, without regard to the principle, the mode or the description given by Reis. It may be conceded that any one skilled in the art can, in the light of present knowledge, accomplish this; but it proves nothing except that those who know how can so adjust and arrange the Reis transmitter that it ceases to be a make-and-break device which will not transmit quality, and becomes a microphone, which will. The only witnesses produced by McDonough who claim to have been able to transmit speech by means of a Reis instrument, when called upon to explain the conditions, practically concede this.

If, therefore, Reis never invented a telephone or transmitter capable of transmitting articulate speech, if the art of transmitting speech by a transmitter was unknown, and McDonough makes no claim to have invented more than a receiver to co-operate with a Reis transmitter, what reason is there to open up the interference to enable McDonough to introduce evidence of operativeness, that the Reis transmitter does transmit quality? He could without doubt produce witnesses to testify that they to-day could make the Reis transmitter transmit quality; but is it not clear that that is not the question at all? The question is: Did Reis possess, and does McDonough's application show, the knowledge of the principle of construction and mode of operation which explains the transmission of speech (if they ever did transmit it), and which, without later knowledge and discoveries of others, could have communicated that knowledge to the world? This question has already been sufficiently answered in the negative.

What has been said in Gray's case in regard to the claim that a receiver of multiple tones is also a receiver of quality, because of its potential qualities of responding to every variation in the magnetic and electrical force, is equally pertinent in its application to McDonough's receiver. This appears to have been the view of the Examiner of Interferences; at least this result would seem to follow the adoption of his views; but the Examiners-in-Chief and the Commissioner disposed of the matter as stated. Say the Examiners-in-Chief:

"Gray formerly insisted, and Edison and McDonough still insist, that not only the art is of their invention, but the apparatus also, and it is only by including an articulating transmitter in this issue that the question of priority as to the receiver can properly be determined.

"If the construction of the issue given by the Examiner of Interferences is to prevail, and priority be awarded to a party who had no articulating transmitter, it would result that an experimenter who had tried to transmit speech and failed, or one who had never tried, should so dominate the art that an inventor who had worked out the idea, patented his process of carrying it out, introduced it to the public and put it into extensive use, could not practice the art which he had created without being tributary to his unsuccessful rival."

This construction of the issue was insisted upon by McDonough throughout the interference, not only when Bell moved to re form the issue before Commissioner Paine, but ever since, up to the present petitions. Not only is it the correct construction, but McDonough cannot, at this late hour, ask to have a different one given to it as a ground for rehearing.

As frequently stated by me, in view of the state of the art, when McDonough's application was filed no one could secure a broad claim for a receiver *per se*. A receiver of tone or pitch would not have been patentable in the absence of the invention of a transmitter which would transmit tone; and while it is true that a receiver of quality will necessarily respond to tone, yet the reverse is not necessarily true. As to such a receiver, it is dependent upon a transmitter through the umbilicus of patentable combination and necessary union, and cannot be said to have been discovered or invented until a transmitter of articulate speech had been invented or discovered.

It is insisted, however, by counsel for McDonough that speech was occasionally transmitted by the transmitter constructed after Reis; and whether it occured accidentally and was attributed to the wrong cause or mode of operation, it was articulate speech, reproduced and delivered by the magneto diaphragm-receiver; and that while McDonough might have been ignorant of the mode of operation of the transmitter he was not of that of the receiver, whose functions had long been known. This, however, is, in effect, a complete reversal of all that McDonough has insisted upon heretofore, and eliminates the articulating telephone from the issue and leaves remaining only a receiver. Why McDonough insisted upon the former construction of the issue, unless he thought it the correct one, does not appear, except he may have feared that as to a mere receiver Edison, Gray or Voelker might antedate him. Evidently he cannot be permitted to secure an award upon a limited issue which puts all his adversaries out of the case, and then insist upon another and broader construction for himself. Not only this, but the relation between the receiver and transmitter is such that the invention is not complete as to the receiver until it is as to the transmitter also. They are one in the conception and completion of invention, and cannot be divided or separated. It could not be known that such a receiver wonld reproduce quality until a transmitter could be found to transmit it. If quality were transmitted accidentally and only occasionally, it could not be certainly and absolutely known but that the failure to transmit regularly and when desired was due to a defect in the receiver. In other words, it required a result which could be controlled and relied upon, which could be repeated at will, and that the construction and mode of operation should be known and understood as required by the patent law. This involved the transmitter as well as the receiver, and until a transmitter had been made which would successfully transmit speech, whose construction and mode of operation were understood, there could be no invention of a receiver, within the meaning of that law.

It is urged most strenuously, however, that this question of operativeness is one belonging to McDonough's case *ex-parte;* that in the interference the Office is bound by the action of the Primary Examiner who declared the interference, and that the only mode of considering or reviewing that question is to remand the case to the examiner and give McDonough an opportunity to be heard and present proofs before him. Further, it is insisted that when the right to a patent is denied for want of operative-

ness or utility, it must be by rejection, by the Primary Examiner giving the applicant his right of appeal; but this view cannot be maintained. The Commissioner, as the ultimate head of the Patent Office, has the power to withhold a patent which in his judgment ought not to issue; but the present question does not depend upon the power. There are two modes of rejecting an application: one upon references, want of utility, etc., as an *ex-parte* case; the other through the procedure of interference. The former may be appealed from the Commissioner to the Supreme Court of the District of Columbia; in the latter, the decision can be reviewed only by a bill in equity.

The statute requires an interference to be instituted whenever, in the opinion of the commissioner, there is pending an application which interferes with another or with an unexpired patent. This interference was declared at a time when the nature of the telephone was not so well known and understood as now. I am not prepared to say but that a motion to dissolve should have been sustained if urged upon the ground that McDonough and some others of the parties did not disclose an operative invention. A motion to reform was made, which, had it been sustained, might have remanded McDonough's case to the Primary Examiner; but he opposed the motion and insisted upon the interference and elected that mode of trial. The trial has progressed through several years, and a final decision has been reached. There is not the slightest doubt that in determining the question of priority in such interference proceeding it is right and proper for the Commissioner to determine and pass upon the entire merits of each invention involved, including utility, operativeness, etc. The very question involved is, When did the respective parties first make the inventions set forth in the issues? If the evidence shows that one of the parties never made any invention, as defined in the statute, and consequently is not entitled to an award of priority, while another party did and is so entitled, the Commissioner is unquestionably authorized to so decide and award priority of invention accordingly. He possesses the power in such case to dissolve the interference if he thinks best to do so, but he is not required to do it. In cases of doubt, when he is not certain as to the want of operativeness, he may very properly suspend or dissolve the interference, remand and make the case *ex-parte*, giving the right of appeal, so that the question could come back to him illuminated by the action of the Primary Examiner and the Examiners-in-Chief. If the doubt as to operativeness should be resolved in favor of the applicant, the interference would be reinstated and decision made accordingly; but where there is no doubt, when the question is one settled in the Office, settled in a number of circuit courts and by the Supreme Court of the United States, such a course cannot be seriously considered.

This is all that is asked by McDonough. His petition is, in effect, a motion to dissolve and be permitted to establish to the satisfaction of the Patent Office the operativeness of the invention. He claims that, in consequence of the collusion and the manner in which the interference has been conducted, he has been deprived of an opportunity to do this. It is expressly stated by his counsel that "it is not supposed to be possible in another hearing that any addition to the testimony could be made." He was offered, on the hearing before me, opportunity to present any experiments or tests proving his case, but none were submitted. The question of collusion has been disposed of. The record shows that Bell in taking his testimony directly attacked the operativeness of McDonough's invention, and he had knowledge of the fact personally as well as by counsel. He had ample time allowed him to rebut this evidence and establish all he could; but he took no such evidence. Neither did he ask the Office to enlarge the time, nor did he make any motion in that direction. Having had all these opportunities and neglected them he cannot now complain if it is denied any further time; but it would not avail him if he were given. The alleged fact is incapable of being established.

It thus appears that McDonough's application has received the consideration provided for it under the statute. The interference has been pending since 1878. Final decision was rendered by the Commissioner on March 3, 1885, in which it was held that McDonough had never invented a speaking telephone, and consequently was not entitled to an award of priority, as against Bell, who had. The present petitions ask me to vacate this decision, remand the case, etc. It is to be disposed of upon the principles applicable to new trials.

I am not convinced that there has been any error or mistake in the former decision: but, on the contrary, I am satisfied that another trial would necessarily result in the same conclusion. McDonough's petitions are therefore denied.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

THE CONVENTION AT CHICAGO, FEBRUARY 19-21, 1889.

The ninth convention (fifth annual meeting) of the National Electric Light Association was held in Chicago, February 19th, 20th and 21st. The sessions were held in the Exposition building.

TUESDAY'S PROCEEDINGS.

In calling the convention to order, the president, Mr. S. A. Duncan announced that, in the absence of Mayor Roche, the convention would be welcomed to Chicago by city electrician John P. Barrett.

Mr. Barrett then addressed the convention as follows :—

Mr. President and Gentlemen of the Convention:

His honor, Mayor Roche, requested me yesterday to say to you that as a subject of vital importance to the city of Chicago was being discussed this morning in Springfield, it was absolutely necessary that he be there, but he hoped to pay his respects to this organization to-morrow, or sometime during the session. He also requested me to extend to you the courtesies of the city, the freedom of the town, but on looking over the great number of my old friends whom I see here this morning, I am satisfied that the city is not large enough to contain all of you, and, therefore, I include, in your welcome to the city, the parks and the boulevards.

The president briefly expressed the thanks of the association for the welcome of the city authorities, and then made his opening address.

THE PRESIDENT'S ADDRESS.

Gentlemen of the National Electric Light Association:

But few of the gentlemen of this country who are commercially connected with the manufacture and distribution of electric light and power, and the apparatus used therefor, are aware that five years ago this month, a handful of men met in this city and organized a movement which has grown into the large and powerful organization of which we are members, and which is in session at the present time.

The industry of electric lighting at that time was carried on with all the enthusiasm which comes with a new undertaking, and with the mistakes which are sure to arise in the commercial introduction of any great industrial agency. The gentlemen engaged therein, strangers to one another, working independently, with no attempt at harmony, with but little knowledge of one another's methods of business, with no established custom or precedent to guide them, came together for the purpose of deriving those benefits which invariably result from the deliberate discussion of those mooted questions which are common to the experience of all electric light men.

To even enumerate the topics which have been discussed at the various conventions of this association, the reports which have been rendered by special committees, the papers which have been presented by recognized experts in the various departments of electrical engineering, and the discussions which have taken place between those well qualified to speak, would consume more time than your president feels at liberty to take for such a purpose from this association. Fortunately, the association is in possession of a complete set of published proceedings from the first convention down to the present time, and these volumes, many hundreds in number, now reposing in the electrical libraries of this country and abroad, testify to the steady and yet rapid growth of the industry and the increased information on the part of the whole electrical fraternity on the general subject of electric light and power. It may be remembered that in the early days of this association the chief question before the electrical fraternity was the then all-important question of arc lighting. The incandescent light had scarcely come into commercial use. No sooner had the questions involved in arc lighting been solved by the natural pressure of public demand than the complicated questions involved in the distribution of incandescent lighting absorbed the attention of the fraternity, and occupied the meetings of this association. Following closely upon the problems involved in incandescent lighting came the question of electrical distribution of power, first for stationary motor purposes and afterward for the purpose of electrical locomotion. This question is to day, perhaps, the most important one before the electrical fraternity. To say that electrical power is not to-day a success would be to reflect upon the

scores of electrical railways now in successful operation in this country, and upon the thousands of electrical motors that are every day commercially serving the wants of man.

Electric light and railway statistics.	February, 1888.	August, 1888.	February, 1889.	February, 1888, to February, 1889.

Miles of single track in operation	....	138	" 157.5	295.5
Miles of single track under contract, not yet in operation	....	189.5	" 84.25	273.75

We may here profitably consider some figures indicating the growth of the electric lighting and power industry, the increase in the number of central stations, arc and incandescent lamps, electric motors and electric railways now in operation. At the meeting of this association one year ago, it was estimated that there were not less than 4,000 central station and isolated plants in operation in the United States. From the accompanying statistical table, it may be seen that the number of central station and isolated plants at the August meeting of 1888, was 5,351, and at the present time is 5,747. This shows an increase during the first six months of the year, of 1,351 central station and isolated plants, and an increase during the latter half of the year of 396, making a total increase during the year of 1,747 plants. Figuring in percentages, the increase during the first half of the year was 33.8 per cent. in the total number of central station and isolated plants, and during the latter half of the year it was 7.4 per cent., making a total increase for the year of 43.7 per cent. It was estimated a year ago, that there were 175,000 arc lamps in daily use in the United States. Six months ago I found upon investigation that there were 192,500. At the present time I find that there are 219,924, making an increase during the first half of the year of 17,500 arc lamps, and during the latter half of the year, an increase of 27,424, making a total increase of arc lamps in use during the whole of the year of 44,924. Figured in percentages, the increase the first half of the year shows 10 per cent., the second half 14.2 per cent., making a total gain of arc lamps for the year of 25.6 per cent. A year ago it was estimated that there were 1,750,000 incandescent lamps in use in the United States. Six months ago I found that there were 2,142,440. At the present time there are no less than 2,504,490, making a gain during the first half of the year of 392,440, and during the latter half of the year of 362,050, or a total gain for the year of 754,490 incandescent lamps. Figured in per cent., it shows a gain during the first half of the present year of 22.4 per cent.; during the latter half 16.9, a gain during the whole year of 43.1 per cent.

It is also interesting to notice what the increase in capitalization has been in electric light companies of the United States during the year. During the first half of the year the increase was $42,210,100 ; during the latter half it was $27,187,634, making a total gain during the year of $69,397,734.

It is also interesting to note some comparative figures upon the electric railway industry. Six months ago there were 34 electric railroads in operation in the United States. During the last six months there has been an increase of 19, making at the present time a total of 53. Six months ago there were 83 roads in process of construction. There are 39 less at the present time, making the number of roads now under construction, not finished, 44. Six months ago there were 39 electric roads incorporated in the United States upon which construction had not yet begun ; at the present time there are 42. Six months ago there were 223 electric cars in operation. Since that time 155 have been put into commission, making, at the present time, 378 cars in operation. Six months ago there were 244 cars under contract but not in operation. This number has increased by 185 during the last six months, making a total of 429 electric cars at present under contract but not running. Six months ago there were 138 miles of single track in operation ; during the past six months there has been an increase of 157½ miles, making a total at the present time of 295½ miles of single track in operation. Six months ago there were 189½ miles of single track under contract but not in operation. At the present time there are 273¾ miles of single track under contract but not in operation. It would be profitless for me to draw elaborate deductions from these figures ; they tell for themselves the story of prosperity and rapid growth throughout every department of the electric light and power industry.

Acting under resolutions passed at the last convention, the president of this association established a headquarters in the City of New York, in charge of the secretary and treasurer, on the first day of October, 1888, which action was confirmed by the executive committee on November 19. From this office has been carried on a voluminous and elaborate correspondence with the whole lighting and power fraternity of this country, not only upon the subject of the work of the various committees of the association, but also in regard to this most important feature, the exhibition of electric light and power apparatus. For the first time in the history of the National Electric Light Association, this has received the prominence which it merits. The exhibit which appears in the other rooms of this building testifies not only to the interest which is shown by the electric lighting and power men of this country in the apparatus which is now before the market, but it also shows the fact that the manufacturers and dealers in apparatus and supplies are willing to put themselves to expense and trouble to bring their wares to our notice in a suitable and proper way, when we are gathered at our meetings. Although this movement originated prior to the last convention and the correspondence pertaining thereto has been carried on by the New York office, I wish to say that much of its success is due to the admirable and methodical management of the chairman of the executive committee, Mr. B. F. Sunny, of Chicago. We are gathered at the present time, gentlemen, not only for the purpose of seeing an exhibit of the latest forms of electrical apparatus and supplies, but primarily for the purpose of listening to papers and discussions upon all important electrical questions. I will not burden you with a detailed account of these reports and papers and discussions which will come before this body. Some of the subjects deserve special mention. Petroleum for fuel first received attention from this body at its last meeting. At this present meeting several papers will be presented upon this all-important subject. The question of the materials of underground conduits in relation to the insulating materials of cables will also be treated. The mooted question of static charge on underground cables and the attendant puncturing thereof will also be the theme of an elaborate paper. Electric light stations as fire risks will be comprehensively treated by a recognized expert in fire underwriting who has given especial time and attention to this particular branch of the subject. The question of municipal lighting, which is pressing upon the electrical fraternity to-day, will be the subject of one or two papers, and no doubt of a profitable discussion. The numerous committees of this association have reports to make upon subjects which will be of much interest to all. The committee on underground conduits and conductors has carried on an enormous correspondence with the entire electric lighting fraternity of this country, and it seems eminently proper that the information they have gathered should be presented in this city of Chicago where the subject of the undergrounding of electric lighting wires has been more practically carried out than perhaps in any other city in the world. This question, which is at present one in which diverse opinions are held by men of equal professional standing, is one which this association cannot afford at the present time to ignore or overlook.

"This association is at the present time in a flourishing financial condition. By this we do not mean that we are rolling in wealth, but that we are comfortably able to pay our bills. Since our last meeting the entire membership roll has gone through a revision, the memberships at the present time being vested in individual names instead of corporations. This has, of course, involved an enormous amount of correspondence and a vast outlay of time and trouble. It has, however, been successfully accomplished, and at the present time the roll of live, new members, testifies to the wisdom of this action. Although the association offers its membership to every gentleman actively interested in the electrical distribution of light and power, it is undisputed that it should contain more than three times its present number. It is believed that the association is now on that "tide in the affairs of men which leads on to fortune." With the proper exercise of care in the management of the association, it is felt that the enormous growth of the industry and the consequent influx of hundreds of men into its ranks will lead to a much greater increase in the roll than there has ever been before. The gain of new members since Jan. 3 evinces the fact that an interest is being taken in the association by the community at large."

At the call of the roll about eighty members responded.

On motion of Mr. J. F. Morrison, it was declared by vote that,

during the session of this convention, twenty-five members be considered a quorum for the transaction of business.

On motion of Dr. O. A. Moses, of New York, it was voted that a committee of five on revision of the Constitution of the Association be appointed, and be directed to report at the next regular meeting.

The chair announced that he would name the committee later on.

A motion by Mr. Geo. M. Phelps, of New York, that the convention proceed to the selection of a committee to nominate officers for the ensuing year, and to select a place and time for the semi-annual meeting, was laid on the table.

Mr. Allan V. Garratt then read his report, as secretary.

SECRETARY'S REPORT.

Total number of members on previous record...	189
Number of old members who have resigned or do not reply .	76
Leaving of the old membership now in good standing.......	113
New members added since Jan. 3	62
Making membership paid up on Feb. 18, 1888...............	175
The treasurer also has letters requesting their names to be placed on roster, but not accompanied with checks...	23
According to the constitutional provision therefor, the names of the twenty-three gentlemen cannot be added to the books, though they would swell the roll to...............	198

It was moved that the secretary's report be accepted and referred to the executive committee.

Mr. Garratt read his report as treasurer, as follows:

The last treasurer's report rendered to the association shows a balance of $1,935.23. This has not been received by the present treasurer, and the present account will begin with no balance. The receipts between Nov. 20, 1888, and Feb. 18, 1889, are $3,712; expenditures, $100.08; cash on hand, $3,611.92.

There are bills outstanding against the association incurred by the treasurer under advice of the chairman of the executive committee; when paid from the funds now in the hands of the treasurer there will be a balance on hand of $2,556.18.

The report was referred to the executive committee.

The President—The executive committee is not prepared to report, and if there is no objection further time will be granted. The next order is reports of special committees. The first is the report of the committee on patent legislation by Mr. Steuart of Baltimore.

REPORT OF COMMITTEE ON PATENT LEGISLATION.

Arthur Steuart:—I have only to make a report to you of what has been done during the past six months, and to state that we have accomplished something in the direction in which we have been striving: we have not done all that we hoped to do, but we feel that we are in a position to carry on this work with success in the near future. At the last meeting of this association held in New York, I had the honor to report to you that the bill which we had introduced in Congress was pending before the judiciary committee and that I had reason to expect that the committee would make a favorable report on our bill and recommend its passage by Congress. Since that time they have made a report, and I will read the report which they have made.

Mr. Steuart then read the reportof the House Judiciary Committee on the Court of Patent Appeals Bill (see ELECTRICAL ENGINEER, p. 508, vol. vii.)

After reading the report, Mr. Steuart made the following remarks:—

At the last meeting of the association, I read in your hearing letters of recommendation which I had received from the members of the Supreme Court of the United States, recommending the passage of this bill and the establishment of this court. I have in my hand a letter from the secretary of the president of the United States, in which he says that he has given the matter very careful consideration and is deeply interested in the establishment of a court of patent appeals. I also have here a quotation from the President's message of December 3, 1888, in which he says:—

"The crowded condition of the calendar of the Supreme Court of the United States, and the delay to suitors and denial of justice resulting therefrom, has been strongly urged upon the attention of the Congress with a plan for the relief of the situation, approved by those well able to judge of its merits."

I have, finally, a letter in my hand from the chairman of the judiciary committee who made this report and who has our bill in charge, and who is doing everything possible to have it pass. Together with the chairman, I have moved all the powers that were at my command during the past six months to secure a time for the consideration of our bill. There is no opposition to it whatever. There is no reason why it should not be passed, except that the calendar of the House is so overcrowded with other bills and the time of the House is so occupied with political matters, that nothing of a private nature can be expected to be acted upon. I have here a letter from Judge Culbertson, in which he says: "The committee on rules did not consider favorably the proposition to give the committee on the judiciary time for the consideration of our bill for a court of patent appeals. The committee on rules has entire control of what bills shall be considered, and unless they give the time for consideration no bill can get place before the House.

It is simply buried under an enormous mass of other matter. But the bill is in shape for introduction into the next Congress, and everything is ready for us to begin work again in November, with every reason to expect that we will succeed. We began to consider this matter at the early part of the present fiftieth Congress. It took six months to get the bill into such form as we could all agree upon. It was filed in April. It took me until the first of September or latter part of August to get this report from the judiciary committee favoring the bill and recommending its passage. Since then you have heard its fate; it has lain with thousands of other bills.

The report was ordered filed.

The committee on transportation reported its success in obtaining reduced fares from all points east of Chicago, Peoria, St. Louis and the Mississippi River.

The President—The next committee to report will be the committee on Insulation of Wires and Installation of Plants.

Mr. Morrison—The duties of that committee are of such a character that no one engaged in the electric lighting business would care to attempt to fulfill them. It practically involves a decision as to whose wire carries the best insulation. We have carried upon our committee lists for several years this committee on insulation, and we have never yet had a report from them. Professor Barker, Mr. Hering, Professor Houston and a large number of scientific gentlemen, were assigned to this duty at one time, and the prospect was that we would get from them a report; but when the time came, owing to the inability of the association to provide the scientific instruments for the tests which were necessary to determine certain qualities of insulation and for other reasons—notably, the lack of an appropriation to be placed at the disposal of these gentlemen, and without which they could not operate to any advantage—they were unable to make a report, except a partial one, which I take it is now among the archives of the association. With this condition of things before us, and believing that we are only lumbering up your committee list by retaining this and perhaps some other committees upon it, I move you, sir, that that committee be discharged from further consideration of the question.

Mr. Morrison's motion was carried, and the committee was discharged from further duties.

The Chairman of the committee on Electrical Education reported that no action had been taken, that the proposed establishment of electrical courses at Columbia College and elsewhere, rendered action by the committee superfluous, and asked for its discharge.

The report was accepted and the committee discharged.

The President—Before we adjourn, the chair desires to state that he has appointed as a committee on Revision of the Constitution, Dr. Moses, of New York, A. J. DeCamp, of Philadelphia, M. J. Perry, of Providence, Henry D. Stanley, of Bridgeport, and W. L. Candee, of New York.

The convention then adjourned till Wednesday morning at 10:30 o'clock.

WEDNESDAY'S PROCEEDINGS.

Upon the calling to order of the convention at 11 o'clock, Dr. Moses, on behalf of the Central Electric company of Chicago, agents of the Okonite company of New York, presented President Duncan with a gavel, hastily but cleverly and handsomely made of a piece of cable.

The President gracefully replied an acceptance.

Mr. Eugene T. Lynch, Jr., read the report of the committee on Underground Conduits and Wires, as follows:—

REPORT OF COMMITTEE ON UNDERGROUND CONDUITS AND CONDUCTORS.

Gentlemen of the Electric Light Convention:

At the eighth meeting of the National Electric Light Association, held in New York on August 29th, 30th and 31st, the following resolution was offered and adopted:

Resolved, "That a committee of five be appointed by the chair to examine into and report upon the system of underground conduits, with underground conductors and conduits now in operation, and the number of wires actually in use in these conduits, and to report at the next meeting of this association."

The president appointed Messrs. Lynch, Barney, Kerr, Davis and Crocker as members of that committee. And as chairman of that committee, I beg leave to submit to the convention the following report:—

As the resolution called for a compilation of all data connected with the actual placing of electrical wires underground, your committee deemed it advisable to send out a circular, calling upon and asking all the local electric light companies for the results of any practical tests that they had made.

To carry out this idea, they caused to be printed the following circular:—

"*From the Committee on Underground Conduits and Conductors:*

"*Gentlemen:* A committee was appointed at the semi-annual convention of the National Electric Light Association, held in New York August 29th, 30th and 31st, to investigate and collect all data relating to underground wires and conductors, both in this country and Europe. It is the intention of this committee to present this report at the Chicago convention of this association, which will be held on February 19, 20 and 21, 1889.

"So many erroneous statements have been made, from time to time, regarding experiments or tests with underground wiring, that the committee (in order that it may hear both sides of the question) feels that it is necessary to obtain all of the most important details and facts regarding this subject.

"Will you, therefore, kindly answer, as far as may be in your power, the following questions, and return the same to the headquarters of the association as soon as possible? Your answers to these questions will be looked upon as confidential, and will not be referred to by name or locality in the report of the committee. It is desirable that you send in your answers at once, as the compilation of statistics takes time."

Yours very truly,

EUGENE T. LYNCH,
Chairman.

ALLAN V. GARRATT,
Secretary.

1. Have you ever placed underground, any electric light conductors, carrying currents at a potential of 1,000 volts or over? 2. If so, state the number of experiments, giving the date of each. 3. What was the length of each individual conductor laid underground? 4. What was the voltage on each conductor? 5. What was the current, in amperes, carried by each conductor? 6. What make and style of dynamo supplied the current on each of these conductors? 7. Were these conductors single or grouped in cables? 8. How many conductors to the cable? 9. What was the size of the conductors used? (In answering this question give the number and gauge.) 0. What was the thickness of the insulation? 11. Who was the maker of the cable? 12. Were the cables laid in any form of conduit? 13. If so, what kind of conduit was used? 14. Describe the manner in which the cables were laid in the conduit—whether drawn in, built in, or otherwise. 15. If the cables were laid directly in the ground, describe the method of laying them. 16. Was there more than one duct in the conduit? 17. If there were other ducts, what was in them? 18. Did you have exclusive control of the conduit? 19. What was the total duration of your experiments? 20. Did the cables work satisfactorily during the entire time of your experiments? 21. If not, how long did they work satisfactorily? 22. If the cables failed to work satisfactorily, to which of the following causes do you attribute the difficulty? Please answer as fully as possible: *a*. Defective insulation; *b*. Defects in joints; *c*. Defects in making connections from cables to lamps.

These were sent to all of the local electric light companies, and in response to them we have received 130 answers. In presenting and compiling the answers to the various questions that were sent out, we have deemed it advisable to divide them into two classes, as follows: Those who have had actual experience in placing and running underground electric wires and those who have not had actual experience, but whose opinions we have asked. Of the former class there are but seven. We will here give the details of the placing of the wires underground, the duration of tests, style of conduit used, and the general results, that were received in each of these seven answers.

As it was stated in the circular sent out that all the communications would be regarded as strictly confidential, we have deemed it advisable that the names of the companies or individuals should not be mentioned in this report; consequently we will not refer to them by name.

First. The writer has used the underground conductors for three years. Has used wire of three of the most prominent manufacturers. Has discarded two and is now using the third. The cables were carried in a cement pipe, and man-holes were placed at every 250 feet. Cables had been drawn into the conduits, and as a method of facilitating their drawing in, pulverized soapstone had been used for the purpose of avoiding abrasion.

Only one wire placed in each pipe. He states that the wires have not worked satisfactorily, and that he has been compelled to shut down many times, that they are now running fairly well, but he is obliged to keep them under constant supervision and repair. He accounts for most of the trouble that he has experienced by defective insulation, defective mechanical construction, and by deterioration in the insulation in the wires, having had no serious trouble with the style of conduits that he has used. In answer to the twenty-seventh question regarding the practicability of placing his conductors underground, he states: "We are operating some eight miles of underground wire; we wish there were less, and certainly are not anxious for more." In answer to the twenty-eighth question, regarding the difficulties and objections to underground wiring, and whether he considered them commercial, electrical or mechanical, he states: Electrical.—There is no cable that will last with a current from a 50-light dynamo. Commercial—Owing to the large cost of construction and expense of maintenance, and great possibility of breaks, there is consequently poor service and dissatisfaction. He has exclusive control of his conduit.

Second. The writer has made many experiments in which he has used lengths of cable varying from 200 feet to two miles in length, manufactured by most of the prominent wiring companies. Cables have been laid in and drawn in, in his own conduits, conduits constructed of both wood and iron. The tests have usually been of short duration, and have been suspended in each case after a failure of the cable to work satisfactorily. The cause of the failure has been, mainly defective insulation. Defective mechanical construction, defects in laying, defective conduits, injury to cables in laying, or defective joints, have caused very little trouble, the main cause of trouble being in defective insulation, and deterioration, owing to the presence of gas, water and steam.

His opinions, based upon the results brought out by the many tests that he has made, is that "he does not consider it practical at the present time to place conductors underground, the absence of insulation that would stand being the principal reason. If ever the question is settled, the cost would, in his estimation, make it commercially impracticable. In only one instance he had the exclusive control of the conduit.

Third. The company represented by the writer had four circuits underground for about one year. One style of cable only, manufactured by a prominent manufacturer, was alone used. The wire was drawn into a composition conduit, which had manholes at the corners.

Quite an amount of trouble was caused in the start of, by difficulty caused by abrasion to cable in drawing the wire into the conduit. The experiments were continued for one year. They caused a great deal of trouble within the lighting contracts, and at the end of that time were abandoned. He considers his chief troubles to be defective conduits, water in the conduits, and deterioration of the cable, also trouble in defective insulation, defects in the joints, and trouble in making connections through iron pipes from the conduit to the surface.

His opinion, based upon the results of the tests that he has made, is that he does not consider it practicable to place his wires underground, and states: "I don't know of any system that has yet proved satisfactory;" and further states: "I know of no system to-day which, even at any expense, has proved satisfactory, except a system of subways built large enough for men to walk through their entire length."

In answer to the difficulties of placing wires underground, he states that he considers the difficulties to be commercial, electrical and mechanical perfection, and still not be so expensive (in the end) as to make the commercial objection insurmountable.

We are all in the business simply to make money, and the commercial objection must be met just as much as any other. He did not have exclusive control of the conduit.

The ordinance passed by the common council in his city in 1886 stated "that their committee had examined the subject and found the putting of all electrical wires underground feasible, and ordered all wires within a few months, and those outside of this district, underground within one year." He has been brought before the court a number of times on complaint of the city attorney, but nothing yet has been done in the matter.

Fourth. The writer has made two experiments during the last summer, one of which was a failure, and the other a partial success, though the duration of the second test and the position it occupied in the circuit was such as to give little importance to the result. The wires were pulled into a wooden conduit, there being two ducts in each conduit. Cables did not work satisfactorily. He states that the failure is due entirely to defective insulation.

In answer to the question if he considers it practicable to place his conductors underground, he replied, "We do not, with any system known at present."

In answer to the last question, concerning the difficulties and objections to placing wires underground, he states: "The difficulty is particularly commercial, though I have seen no system which I think will properly insulate the conductors."

Fifth. The writer has placed two circuits underground about the first of the present year. The cables used are those manufactured by six of the most prominent companies. They have been drawn into an asphalt conduit, 12 ducts in each conduit. The duration of his experiment has only been about a month and a half, and he states that it is too early to tell what will be considered the result of the experiment.

In answer to the question if it would be considered practicable to place the wires underground, he states, "Have seen nothing yet that will answer."

In answer to the question regarding his opinion regarding difficulties and objections to going underground, he replies,

"Chiefly commercial, partly electrical, and partly mechanical." He has exclusive control over his own style of conduit.

The writer has had wires in the conduits for about five years. The mains were carried through the streets in a composite system of conduits, the connections are made from the system to the cellars through iron pipes, and the wires are conveyed then through cellars, connection being made from the cellars to the houses. The cellars run completely around the block, and permit of free access to them for the purpose of repairing or making connections to wires.

He has used three different kinds of wires in the conduits, the cables now in use having been in position for about 13 months; although he has had trouble with them, he claims that satisfactory service can be maintained in his particular locality, as he considers the question of the distribution of power and light an exceedingly simple one in his city, which is probably the only city which is so fortunately situated.

He has in all about 32 circuits. He states that he is on the right track regarding the placing of wires underground, and that the system such as he operates will run satisfactorily. The cables that he is using are guaranteed for three years. The trouble that he had with his first wires was mainly due, as far as he can ascertain, to the fact that the insulation surrounding the wires was not of sufficient thickness, and the main conduits themselves were not dry, He controls his own conduits exclusively.

The writer has made some practical experiments and tests with cables underwater; these were manufactured by two of the most prominent companies. The cables did not, however, work satisfactorily, lasting, as they did, from three months to one and a half years. He lays the cause of failure to the effect of water upon the cable, and the deterioration in the insulation of the wire. His opinion, based upon the tests he has made, is that he does not consider it practicable to place his conductors underground; considers that the difficulties are electrical, mechanical and commercial; had exclusive control over such conduits as he used.

In summarizing the results of the experiments in these cities, in one case only did the electric light company place its wires underground willingly; in all others they were forced to do so by the local authorities.

In only one instance have the experiments or practical workings proved satisfactory; the only other case that they did not report adversely being where the wires had only been in operation about 40 days. The average voltage that we used on all the circuits tested was 1,893 volts; the current was 10 amperes; the average thickness of insulation over wires was 9.32 of an inch, and the average length of cables tested in each case was about 4,600 feet.

In considering the second class of answers, namely, those who have not yet made any extended practical test, their answers have been directed mainly to the last four questions, the first two of which relate to action by the municipal authorities, and the last two consider the practicability and the difficulties of placing wires underground.

In very few of these cities have the municipal authorities yet taken any steps toward action upon the matter, having been delayed in awaiting the solution of the underground question in other cities.

In answer to the 27th question, asking them if they considered it practical to place their conductors underground, 104 have replied that their opinions, based upon tests that they have seen and such information as they have been able to obtain, both in this country and abroad, is "that it has not been practical to place the wires conveying high tension electric arc light currents underground."

Two have answered that they considered it practical to do so, but state that at the present time they have no wires underground.

In answer to the 28th question, which asks their opinion regarding the greatest difficulties to be met with in considering the placing and operating of underground wires, they all unite in the opinion that the difficulties are mechanical, electrical and commercial.

They consider that the question of obtaining a satisfactory conduit has not been properly solved; and that even if that should be solved in the future, we cannot even at this time obtain a satisfactory insulation for the wires that will not deteriorate within a few years, and become perfectly useless as an insulator when subjected to the action of steam, water and gas. The great difficulty of making connections for buildings and lamps, and the absence of any satisfactory system of subsidiary conduits, is considered by all as a bar to successful operation, as the difficulty of drawing in cables without abrasion to the insulating covering, even with the most careful handling, is very great.

The commercial objection is considered a very great one, as not only is the first cost about eight times heavier than that of an overhead system, but the repairs to the cables due to the deterioration of the insulation and other defects caused by mechanical or electrical deficiencies, would be very much heavier than the expense of operating and maintaining overhead systems, and that the prices at which they are now furnishing the electric light would have to be very materially increased to meet these extra and very heavy expenses. A system of tunnels through all the principal streets is considered to afford the only means for the solution of this problem.

There are many other responses to the circulars, in which the writers state that they have had no experience with underground lines, and have not yet considered the question in the light that we have placed it before them.

The committee also sent a letter asking many of the questions that were sent in the circular, to all of the electric underground wire companies, and in response received quite a number of communications from the cable companies. Most of them said that at the present time they were unable to give any information in regard to underground wiring, as they have had very little experience with wires for that purpose, but that they do not doubt that in the future the state of the art will permit of the wires being placed underground, and that their particular company will be well equipped for doing so.

Other companies reply that the wiring of their system that has been used for underground purposes has been for potentials under 2,000 volts, and that they have met with entire success with potentials of a system with 1,000 volts. And they do not anticipate in the future that they will have any trouble in furnishing wire to meet the requirements of the electric lighting companies, but at the present time they have not yet done so.

They unite in stating that they think that the question of the insulation of high voltage of currents should be solved by the using of good, durable, thick insulation.

Their experience in conduits has been, that they do not want creosoted wood, but would prefer to have their wires buried in the ground or under water, and would recommend at the present time that single conductors should be used.

They seem to be about evenly divided on the question as to whether lead-covered cables should be used for underground purposes.

The report was accepted and placed on file.

Mr. J. P. Barrett—I want to say that we have had underground service here in Chicago, for the last 13 years. We have been using electric lights with underground circuits for the last six years. The municipality purposes to extend its electric light system indefinitely. When I see in this convention gentlemen who are prepared to guarantee to construct and maintain conduits in any form that you require, and right alongside of them, gentlemen prepared to furnish you conductors that will carry anything you want—in face of these facts, I say, I find it stated by this report that it is an impracticability. We think pretty well of it here, and we have got plenty of it in service.

Mr. W. H. Johnstone—I have been in the underground electric light business, for five or six years. I have been operating a plant in Philadelphia during that entire time with perfect and uniform success. We have constructed a plant in New York for the same purpose at a very great expense. The reason why gentlemen say the conduits are not practicable is that they have not seen them. In 1883, we laid two miles of conduits in Chestnut street, Philadelphia. At that time the state of the manufacture of the insulation was in a somewhat primitive condition. To-day the manufacturers have advanced so far that they are willing to offer us wires with a guarantee of three or five years' duration of insulation. Mr. DeCamp, who is sittting in front of me, has had an opportunity of seeing what we did in Philadelphia. His company did not want this thing to succeed, and, therefore, they took advantage of the opportunity to get possession of it. They ran it to suit themselves, and in a very short time announced that arc electric lighting underground was not practical, and that they would have to utilize these conduits for an incandescent circuit.

Now as to conduits, I have spent eight years with them. We started out with the idea of grasping the entire subject. The electrical difficulty we knew we could deal with; the mechanical difficulty was the serious one. The first difficulty was expense Our conduit is more expensive than creosoted wood or asphalt, but when you put it down, you have a comprehensive thing that fulfills every demand, and I challenge any one to ask me a question as to the distribution or handling of an electric light current that I cannot answer and show him how it is done. Now, that iron is the best material electrically, I think, we will all admit. I do not see what this report is based upon.

We are laying in New York city conduits that have cost now quite a million of dollars. There have been laid about four miles, and it has proven satisfactory to those people who were so bitterly opposed to this system. Now we have laid that conduit in Broadway and we are going to have it on 125th street, and I promise you that this coming summer the electric conductors in New York will all go underground, and our good friend, Mr. Lynch, will have to reverse his report.

Mr. J. R. Ecclesine, of New York—I see that most of the communications were from electric light companies whose underground conductors were failures; any success seemed to be overlooked or was not reached by the committee. It struck me also that the report of the committee was made up of objections, and that it was made to support the resolution that had declared in New York that underground conduits were not a success. There

have been, I believe, for some time, underground stations worked successfully, not one of which the report happened to name. I take Professor Barrett's word for it that he has worked underground successfully, and yet the report fails to say anything about his experience. In fact, all the information the report brings is damaging to underground systems. But the resolution that is to be supported by this report, passed last August, was of a sweeping nature. It was the effort of people to say, "we don't want to go underground, and, therefore, we will say boldly we cannot go underground." The electric light companies that have answered the committee are evidently not desirous of going underground; but the people of the country are desirous to have them go underground.

I do not think there is any earnest effort on the part of the committee to find how to go underground, but a very earnest effort to find how not to go underground. At the proper time I propose to move to rescind the resolution of August. I propose to do that not because of the opinions of the people, but because of the facts that exist.

Mr. T. Carpenter Smith, of Philadelphia—I do not stand here to declare that overhead wires are dangerous, or that the wires have to go underground. I believe to-day, after our experience of three years with underground circuits and of six years with overhead circuits, that overhead work properly constructed and cared for, is the safest method of distributing. Considering the amount of power now distributed through electric light wires overhead in the city of New York, or the city of Philadelphia, and comparing it with the accidents that occur every day or every hour with any other form of transmitting power, you find that it is incomparably safer. There are about 200 miles of overhead electric light wires in Philadelphia. There are, I believe, about 100 miles of street car track. Now in these 200 miles of wires we are distributing, say, 3,000 or 4,000 h. p. sixteen hours a day. In Philadelphia last year there was one death from an arc light current. What do we find in the miles of car tracks operated by cable companies? Twelve deaths were caused where people fell off the cars or were knocked down by the cars and were run over. I want to put myself on record as a strong and earnest advocate of overhead circuits where they are possible. They are easily kept in order; if there is anything wrong with them it is quickly seen; but on the other hand I must say I do not consider that this report is at all a fair one to the underground wires. When any company wishes to adopt a new system, using, perhaps, some particular form of electric apparatus, do they go around and ask companies who are not using that system what their opinion of it is? No; they pick out men who are using that system and go to them to see what has been their success with it. They are not content with taking the say-so of people; they try to find out the reasons for its failure. Now I am not aware that I have ever seen that circular sent out by Mr. Lynch's committee. I represent the Keystone Construction Company, Philadelphia, and we are operating an underground station. We are doing so because we could not help it. If we could have gone overhead we would have done so.

We have had a great deal of trouble with underground wires, but have managed to keep our lights going. It has cost us less to do that than any similar amount of overhead wire that I know of. When we went into this thing we went into it in an experimental way. There was nobody in this country who could tell us anything about it. Fortunately for myself, when I first went into the electric business, some seventeen years ago, I served my time in a factory where we made submarine cable. I had an opportunity of seeing a great many accidents that happened to ocean cables. We went out in boats and hauled up the cables and found that the accidents were more mechanical than electrical. When we went into this alternate current business I was met with a storm of assertion that we never could run alternate currents—the induction would be too great. We have had not one particle of trouble from induction or anything but mechanical defects or defective insulation. We have found that lead-covered cable does not get proper handling when it is put in. We instruct our men as well as we know how; we threaten them with discharge if they do not do exactly as we tell them; and then they will go to dinner on a damp day and leave the ends of the cable sticking out to absorb moisture. When the cable was watched carefully we have had no trouble. With cables we do not watch personally in every case they have broken down, and in nearly every case it is because it has taken some damage and the moisture worked back into the cable and found the weak spot in the insulation. Now I think in making up the report or making inquiry as to electric light service underground, that the money which was spent in sending out a thousand circulars to companies who were not using underground wire would have been much better applied in making careful inquiries of the companies who were. I do not consider that experiments made with a quarter mile or half mile or ten miles of cable six years ago have very much bearing on this question; for it is only within the last two or three years that a really intelligent attempt has been made to put in underground service. I am free to say that I consider the question of distribution of high tension arc light currents the gravest and most serious case we have to consider. The distribution of low tension incandescent current we may say has been solved. The Edison company is doing enough with that to settle the question. When it comes to the distribution of high tension alternate current for incandescent service, I am free to say I think it is perfectly practicable and can be made a commercial success. I most sincerely trust that this report will not go forth as the voice of this convention. I think the resolution passed last August stating that the underground work so far was not a success was an ill-advised one. I believe the time has come when this association has to face the music. Underground work will have to be put in, and the sooner you do it, or make some honest effort to do it of yourselves without compulsion the sooner there will be a let-up on this tremendous public pressure. In the centre of a crowded city I think no one who has been in Philadelphia, New York or Chicago will deny that the presence of the poles is a nuisance; they are obstructions and to some extent they are a danger. In small country towns and in outside suburbs, I do not consider that the overhead wires are half as much of a nuisance or a danger as underground wires. Now I want to be thoroughly understood as to what I mean by the danger of a lighting circuit. We have been favored with a large number of communications from a distinguished electrical engineer as to the frightful danger of overhead high tension circuits, and he is very anxious to put an apparatus on all such lines which from the moment of a grounding will shut the circuit off. He wants to do that to protect the eight or ten linemen, who are presumably men who understand the danger of their business and will take proper precautions against it. To do that he is willing to risk the lives of the unoffending public who may be jammed in a ferry-slip or in the theatre or on a large public thoroughfare or in a railroad station by having the entire light shut off instantly, leaving them in total darkness. Now that is a form of danger which I think is infinitely greater than the danger that exists from grounding on a high tension line overhead, which is only interfered with by men who know what they are going to do. For that reason I think that the underground service is more liable to interruption; but against that we have to set this fact, that on an alternating transformer system you can run one of these high tensions grounded. Ferranti, in England, proposes to do nothing else. Under the transformer system each house is a unit; a man who puts his own wire in a proper condition cannot affect his neighbor. With the arc light system you cannot do that; there may be a break, and you will have to let your lights go out. For that reason I propose to leave arc lights out of the question. I am putting up overhead wire every day, and I stand ready to put down underground if anybody will pay the price.

Mr. J. E. Lockwood, of Detroit—I am one of the seven who in answering the report of the committee on underground wires, answered that we had tried the underground system. I represent the Thomson-Houston Electric Light Co., of Detroit, where the underground system was tried for a little more than one year, and was discontinued a little over one year ago to-day. Our current was from 1,800 to 2,000 volts. The discussion on the former underground systems for telegraph and telephone wires, does not apply to currents of over 1,000 volts. I think the questions sent out by the committee were good, inasmuch as they focused the subject down to currents exceeding 1,000 volts. I should like to have Mr. Johnstone and Professor Barrett tell us about circuits of over 1,000 volts. I have understood from reports made to this convention by Mr. Sunny and others, that a large amount of the wire used here in Chicago was taken out last fall. I would like to ask if there are any underground wires now in use here in Chicago, with a potential exceeding 1,000 volts, and if there are any exceeding 2,000 that have been in use for any length of time; if so, just the length of wire in use, the potential of the current and the time it has been in use.

Mr. J. P. Barrett—We started in to use them about a year and a half ago. At that time we put in the Western Electric (Patterson) cable. We put in, say, 12 miles of Western Electric cable and six miles of Kerite. We have now 55 miles of underground cable for the lighting service of the city. In the matter of high tension, if you will ask Mr. Sunny he will give you more information. I understand we have some 1,200 arc lights.

Mr. B. E. Sunny, of Chicago—I stated at the Pittsburgh convention, and subsequently at New York, what the condition of affairs was in Chicago with regard to underground cable. At Pittsburgh I stated that we were in a bad condition; that we had to throw out entirely two different styles of cable, and had finally put in cable manufactured by the Western Electric Co.—a lead-covered cable with very thick insulation, an insulation thickness of three-sixteenths of an inch. At New York, six months later, I stated that with six or seven months' experience we had but four cases of interruption. One of these was a mechanical injury, and two were defects in the cable, and one we could not trace. Since the New York convention we have had no trouble that could be traced to imperfections in the cable. We have had some troubles, but they were owing to poor work in making the joints. From a technical standpoint we are getting along nicely in working arc light circuits underground. Professor Barrett is using a current in his work of about 900 volts—perhaps he gets as high as 1,200 volts. We put through our cables from 2,000 to 3,000 volts,

and sometimes higher. Of course, I cannot say how long the cables that we have now—that have been in use for just about a year, and have only given us four cases of trouble—are going to last, or how long they are going to furnish satisfactory service; but just at this time they seem to be in first-class condition; and we are satisfied with them. Scientifically it is all right; the only objection we have is a financial one. I made up some figures a few days ago, as follows: The cost of circuit reconstruction and maintenance of conduit amounted, for three months, to $9,610.95. That was for 1,194 lamps for eight hours a day for 90 days, or 859,680 lamp hours. You see the cost of underground conductors is a trifle more than one cent per lamp hour over and above what it would cost on an aerial conductor. Now, you will say, if we had aerial conductors we would still have the item of circuit reconstruction. That is very true, but I have left out the question of underground conductors so far as the repair on electrical machinery is concerned. We put $200 to $300 worth of expense every month on repairs to the electrical apparatus, made necessary by our underground cable, so that I think it is perfectly right to say that if our wires were on poles, the troubles I have enumerated would be eliminated. We figure, therefore, that from a scientific and practical standpoint underground cables are all right. From a financial standpoint they are costing us a trifle more than one cent per lamp hour more than aerial conductors. That does not include the interest on the additional cost of the investment.

Mr. T. Carpenter Smith—I would ask Mr. Sunny what rent he pays per mile for each circuit. I know of a case where conduit rent was such that in three years the company could have put down and owned its own conduits, and a great deal better conduits.

Mr. Sunny—The conduit rent is a thousand dollars per mile per year per duct. The duct will hold three electric light cables. So that the rent per mile for conductor is $333.33.

Mr. Smith—We can lay down a 16-duct box, which would accommodate 50 wires at a cost complete of a little over $5,000 a mile.

Mr. Sunny—The item of circuit reconstruction which was included in the $9,610 was for going over joints in man-holes, for pulling out some sections of cable and replacing, and for taking out and renewing some wires under sidewalks. It included everything that we did with the plant that we could not charge to construction, everything that we did to the plant that did not add to its earning capacity. Six months ago we were in good shape; all the reconstruction that we ought to have done was done, and from that time on we considered that any charge that we would have to make for reconstruction would be a charge that we could count on having from month to month, as far ahead in the future as we could see. Nothing that can be legitimately charged to construction is put into that account. It is renewing something that we paid for some time ago. The items of the three months' expense account are: Circuit, reconstruction, $3,105.31; maintenance of conduit, $2,206.54; conduit rent, $3,480; rebate for bad service, $789; total, $9,610.95. The conduit needs a great deal of attention. It is one of the first ever put down. It was laid five years ago. Street rollers have crushed it here and there, and we have had to enlarge some of the man-holes. If you put down a conduit as it can be put down to day, it would not cost so much to maintain it. It would not require three or four men going around town every day in the week pumping out the water and drawing out the gas.

Mr. Lockwood—Then I understand that the expense of the maintenance department, including rebates, is approximately $6,200 for three months; that during that period Mr. Sunny's company has been having its greatest success with underground wires. I would like to know if anyone has actually used underground conductors with a potential exceeding 1,000 volts with a record better than this of Mr. Sunny's

Mr. E. A. Sperry, of Chicago—In the last four years we have been operating on State street, an underground system of 1,800 volts, and 18 to 20 amperes; and entering into the construction of that underground system has been every conceivable kind of cable. I do not think, that our expense account, figured in lamp hours, would reach any such figure, including rental of conduits, as has been named here. We are operating now another station in the city with 1,300 volts, with a record of no shut-down whatever, and a record of over a megohm as actual insulating resistance every morning. This is all underground, and is made of improved modern cable and is put in iron pipes under sidewalks. This being more than 1,000 volts I think comes under the question. There has been a great deal of changing, but that was owing to the pioneer work that we had to do. We had to take what we could get. If a cable did not prove satisfactory we had to pull it out and put in something else. Now, the cables that were used for the first three months are undoubtedly all out. As to the next cables that were put in, part of them are out. I have in mind now one cable, put in three years ago, that is now running successfully. That is to my mind a very good instance of what the cable can be made to do if it is properly put in.

Mr. T. Carpenter Smith—Mr. Sunny said that his rental of conduits and repairs to conduits amounted together to about $5,600. Now he is in the unfortunate position of renting a conduit and then having to pay for it in the bargain, which is always the result where you rent conduits from a company in whose power you are, so to speak. That leaves as the cost of Mr. Sunny's conduit for underground service, reconstruction, etc., $4,000, or about $1,300 a month. I would like to ask Mr. Sunny how many miles of wire there are and how many miles of conduit?

Mr. Sunny called upon Mr. C. H. Wilmerding, superintendent of the Chicago Arc Light and Power Co., to reply.

Mr. Wilmerding—We make out the mileage of underground conductors as about 78 miles. There are laid 90 miles of duct and about seven and one-half miles of conduit. Each duct will hold three wires.

Mr. Lynch—I would like to call Mr. Sunny's attention to the following figures: Rental of conduits, $3,400 for one quarter; that would be $13,600 per year. That would be 13½ miles of duct at $1,000 per mile per duct. That would give only 40 miles of wire. Mr. Wilmerding said there were 78 miles of wire underground.

Mr. Sunny—We have 78 miles of circuit, and I should estimate that there are about 40 miles of that circuit in the conduits; the remainder is under the sidewalks and in buildings.

Mr. Lynch—You do not have to pay any rental for the subsidiary ducts which you use—that is, in the cellars and over the buildings.

Mr. Sunny—No, sir.

Mr. Charles Cooper, of Brooklyn—While this underground business is very interesting electrically, and we are very glad to hear the opinions of the electricians on the subject, to the practical operators of electric light plants it would seem that the matter comes down to this—that the experience so far has not been flattering, and that what has been said in favor of the underground system so far, is from men interested in underground conduits or cables, or by our friend, Professor Barrett, of Chicago, who is in the fortunate position of having the municipality of Chicago to pay his bills. Unfortunately our company has to pay its own bills. Mr. Johnstone, who speaks for the Johnstone underground conduit, mentions his conduit in the city of New York, which has not yet been used. The experience of New York city so far leads to the belief that when his conduit is used it will be, as the others have been, a failure. Mayor Hewitt remarked, the commission in the city of New York consisted of four men, who he supposed knew as little about electricity as any four men in the city of New York; and he added that he could frankly say so, because he was one of the commission. Now, I for one would be very glad indeed to have this system of underground conduits prove a success. In Brooklyn we are very anxious to use it. We have a commission in Brooklyn composed of three of our best known professors of electricity, who, I can say, are honest men, appointed by Seth Low, the reform mayor of the city of Brooklyn. One is Professor Plympton of the Polytechnic, another, Dr. Raymond of the Adelphi academy. Professor Plympton traveled all over the world, and went into cities where he was told that all was underground; coming to Chicago where they did not have an overhead wire, and much to his surprise finding that they had more here than they had in Brooklyn; he has traveled to Paris, Berlin, London and every city in the world where he heard they had used the underground system, and much to his surprise found that none of them had been in successful operation, and came back and, like an honest man, made his report to the mayor of Brooklyn to the effect that up to the present time there is no system that is of practical use for arc lighting. Mr. Barrett has started in the electric light field. Mr. Barrett has the city of Chicago at his back. It is a rich city; it will probably not be so rich when it gets through with this conduit business. When it gets through with the system, when it has used it a few years, it will do just what companies have done,—abandon it. You cannot do electric arc lighting and make it a commercial success with underground conduits.

Mr. Johnstone—The only people that are advocating underground operation, we are told, are those that are interested. Why not? The only people who are opposed to it are those who have money invested in overhead wires and do not want to take them down.

Mr. A. J. DeCamp, of Philadelphia—The criticism has been made that the enquiries had been sent without special reference to the companies that were using underground wires, as being the only ones who could express an opinion or give an experience. The number who responded was comparatively small. In my judgment that is an evidence of the good, hard, practical common sense that has got into the heads of the electric lighting men. I think that a man is a grievous fool at this late day who will spend thousands of dollars to try over again anything that I and seven other men have failed in absolutely. There are three things connected with this underground business. First, insulation; second, some method of distributing your business, and after that is accomplished is it a commercial success? Where is the man to tell what cable or wire will cost with perfect insulation? Now, the distribution of it by some properly constructed conduit comes next. So far as my knowledge goes of general construction, the plan for distribution of wires by the conduit in which Mr. Johnstone is so greatly interested is as good as any, and I am prepared to say better than anything I have seen, because I have used it. I do not agree with him as to its construction of iron, but that is a collateral question, it

can be made out of anything. Now, as to the financial success. A statement was made to me yesterday substantially the same as Mr. Sunny made here to-day as the experience of his company. That must be wrong. One cent an hour added to the cost of lights must be wrong. That exceeds anything that I could ever imagine. Mr. Sunny told me it was substantially correct, and he reiterates that statement on the floor of the convention to-day. Now what does that mean? Our average is something over eleven hours; that means it is going to cost us eleven cents a day. Now I have been in the electric lighting business a long time, and I do not think we could get a dollar of capital into that business on any such representations of cost as that, added to other costs which are large, and which you always have with you. Now Mr. Johnstone refers to Philadelphia, and while I regret that I am dragged into that subject, I am compelled to answer. Mr. Johnstone had been manager of that company, spending one day in the week, I will venture to say, in looking after the details of the station, and the other six days advancing the interests of the conduit company—that is my belief. Mr. Johnstone makes a statement about our buying his company out. I will make no reference to that any further than to say that he sold it out at about ten times its intrinsic value. I accepted that station just as it was. I had nothing to do except to look after the interests of my superiors, the directors, and I said: "I have the facilities at hand to see whether this thing can be made to pay on the basis on which I have been educated to consider things as paying." There were no records of that institution, so far as its internal operation was concerned, that were worth anything. Everything was reported, so far as the circuits were concerned, as being in fairly good order; but there were some defects, owing to the embarrassed condition of the company. They were running a blower and it could not be dispensed with, because of the liability of gas to accumulate in the conduit. Let it be there and we have an explosion. What is the cause of the explosion? Defect in the wires reported in fairly good condition, defects in the insulation causing a spark, and the spark causing an explosion. That does not speak well for the perfect insulation and perfect state of underground wire, and that was a sufficient reason for the continued expense of running a blower, and it was run. Further effort was made to ventilate the conduit and improve it. Then it was reported that there was no evidence of gas. We ran it probably five or six months with from 100 to 130 lights, on short lines. With the 100 to 130 lights the company did not pay its expenses. I am only mentioning this now to show you that there was no financial success in that particular instance. I will also say that there were more than six explosions in the ducts. Nothing having happened to seriously injure the property of the company, the record was not kept very closely, but after the condition of the conduit was reported to me as being in such a shape that there was no liability to these explosions, we had one. That was got out of very cheaply. We settled the damages for, I think, $260, and I considered that we were fortunate. Now, that is the history of the Philadelphia company which Mr. Johnstone quotes, and the only thing that he has to quote. I did what I think any man in this convention would do. I went to the directors and told them we could survive under this thing with an object in view, but the chances of pecuniary remuneration would not justify taking the risk. They followed my suggestion, and we abandoned the arc light business of the station. We were not in incandescent business, but we had that elephant on our hands; what were we going to do with it? I suggested taking up incandescent lighting on a small scale to see if we could get some knowledge of our own out of that experience. A given amount of money was appropriated to enable us to put in a small incandescent plant and run it. The amount of money expended directly in that one object exceeded by a few hundred dollars what I estimated it; but two and a half times as much was spent for what I had no idea would arise in expenses. We found the whole of these conduits from one end to the other were broken and smashed up so that we could not get anywhere through them from accumulated gases, caused by defective insulation. Two and a half times as much money was required to be spent before we could put into anything like decent operation our experimental incandescent station. That station was always run at a loss. I had no interest at stake there except to make that station successful. The capital of that company is $500,000; it was blocked out for one hundred lights; there remains in the treasury of the company a little more than half the stock.

Now as to the comparative cost of operating wires underground or overhead: Leave out the question of rented conduit, I make this statement here that the cost of maintaining overhead circuits from one station running about eleven hundred lights, exclusively on overhead wires for the year 1888, was eighty-two one-hundredths of a cent per lamp per day. In that I do not include the labor item. I have taken the labor of linemen, one-third of whose time is probably engaged on this particular work. It is 1.76 per cent of the cost of the lights. About fifty miles of that wire embraced in the maintenance account was put up in the summer of 1881, and not five miles of that wire has been abandoned or replaced. It is just as good to-day as it was when put up. In this whole system of subway conduits the electric light company have had sufficient experience to make them cautious. They want a reasonable assurance that a thing will be successful and give them a fair return before they put in their money. In Philadelphia to-day the arc light business is practically at a standstill because of this agitation on the subject of overhead wires. Philadelphia is practically stopped in the extension of its business; New York has stopped in the extension of its business on account of the subway question. The business here in Chicago, I will assert, is infinitely smaller than it would be if the light companies had the facilities for running their wires overhead, and so it is all over the country. Now the business in Philadelphia and in New York in proportion to the demand for it is a picayune business.

Mr. F. Ridlon, of Boston—We have had one difficulty in Boston with the underground service, which does not seem to have been touched upon at all. We were very much surprised a few weeks ago to have the insurance people intimate to us that they would have to increase our insurance, because of electric lighting, as they considered it an extra hazardous risk. We felt that it was necessary to know the reason of it, as they had heretofore expressed the utmost confidence in electricity and considered it the safest method of illumination. We got the representatives of the insurance companies together, their experts and their inspectors, and the electric light people, and their statement was that there had been within the past six months a large increase in fires in the city of Boston, occasioned by electric light wires. We investigated each case, and found that a very large proportion had been caused by the underground service, which had been in operation about one year. The amount of underground wire was some forty or fifty miles We have nearly 600 miles of overhead wire in Boston; two or three hundred miles of it has been in operation about six years. The alarming increase of these fires has been within the past eight months; they caused large losses, whereas in the previous five years of overhead lighting insurance companies had not paid one dollar of loss on account of electric light fires. It finally proved that in nearly eight out of ten of these fires they were caused by the underground service, and it is now a question whether we can afford to continue the service which was found to be an extra hazardous risk.

Mr. Weeks—I would like to read a couple of letters from two electricians who are well known not only in America, but throughout the world. The first is from William Hochhausen, of New York, addressed to the editor of the Kansas City *Globe*. The second is from Professor Elihu Thompson. Mr. Weeks then read the following letters:—

NEW YORK, Feb. 6.

To the Editor of the Globe:

In relation to the question of the feasibility of using underground conductors, it must be confessed that very little experience has been had, as yet, with such conductors for the convenience of high-tension arc light currents. Chicago has probably been wired underground for such purposes to a larger extent than any other city in the United States. These installations are of such recent date that it would be premature to pronounce them an assured success. It would seem advisable to watch the working of existing underground circuits for a few years before attempting to enforce burial of a great number of circuits. If roomy, well ventilated subterranean passages were provided for the reception of the electric wires by the municipalities it might be possible for the arc light companies to give satisfactory service, but such structures are very expensive, and would certainly be beyond the means of electric light companies. A wire, merely buried, when insulated as well as our present knowledge of insulating substances will enable us to do, would be liable to give trouble and necessitate the repeated digging up of the streets to effect repairs. The overturning of the soil in city streets will generally cause miasmatic exhalations, and should be prevented as much as possible. It seems that New Orleans will shortly try a system of running wires at a very high elevation, fastened to substantial iron structures placed at street intersections. This plan is likely to prove very successful. This undertaking should be watched with interest by all corporations contem plating a removal of pole lines.

WM. HOCHHAUSEN.

LYNN, Mass., Feb. 10.

To the Editor of the Globe:

It is difficult to formulate any opinion which will apply, without exception, to every instance of wiring. While considerable objection can undoubtedly be urged against the use of overhead wires, particularly as they are frequently installed in electric signaling, telephone and electric light work, objections may also, with equal force, be raised against any system of subways thus far put down. Without doubt the most satisfactory subway arrangement would be to have a sufficiently large tunnel for the passage of workmen, with means for supporting the wires on the sides and roof, thorough ventilation of the subway being always maintained. This would be, however, enormously expensive in most cases, and except for the main thoroughfares of a large city, the expense may be considered to be prohibitive. The difficulty is not so great in dealing with the wires in the main streets, which probably could be put underground whenever the expense was not too great. But the real difficulties are met in minor ramifications which would be needed to reach customers at various points.

The problem of preserving the insulation of underground wires which are exposed to emanations of the soil, leaks of coal gas, steam, etc., is in itself a serious one, particularly with high potential currents, such as are in use in arc lighting. There would seem to be no reason whatever why telephone and telegraph circuits might not be put underground in suitable subways, and the expense would be very much less in proportion than in the case of electric light wires. This would remove a very large portion of the overhead wiring, and also that portion consisting of bare wires and innumerable dead wires of telephone and other circuits, as it frequently does not pay to take down a wire when it becomes disused. This is not the case with electric lighting wires, which are not liable to become dead wires at any time, and which, when grounded or defectively supported, at once give notice of the fact by causing trouble in the system. Most of the crosses and leaks on electric light circuits are without doubt caused by the frail, uninsulated, rough surfaced wires of telegraph and telephone systems falling down upon the electric light wires.

It is my opinion that legislation would succeed best in the undertaking of removing the overhead wire nuisance, for such it undoubtedly is, by a gradual process, first getting those wires underground which can without doubt be put there with an increase of security and certainty of service, as in the case of telephone and telegraph circuits within the limits of a city. What wires are then allowed to remain overhead should be taken care of by enforcing a system of skilled supervision in the placing of them, prohibiting the irregular and random

running of wires from point to point and requiring that an orderly system or plan should be observed, the purpose of which would be to keep the wires together and to allow branches and crossings only at right angles, on neatly constructed and well supported structures. It should also be required that a sufficiently large and strong wire be used so as to resist the action of wind storms and sleet storms.

I think that in many instances the enforced resort to subways, especially such as might be and such as have been constructed by parties having little acquaintance with the nature of the problems to be solved, such as subway companies securing a franchise for such work, and proceeding on such an economical basis that poor construction and unskilled supervision are made to take the place of first-class work, would be a damage to the business of electric lighting, and would, in fact, act as an insuperable barrier to the undertaking of business in quarters which cannot be reached cheaply and easily by overhead construction; in many cases subway construction requiring an outlay which would far more than counterbalance any return from the business itself would be necessitated.

The remarks I have made apply particularly to large cities. For towns of very moderate size I can see no reason why overhead wiring, properly looked after, properly organized and systematized, would not be comparatively free from objections, while the expense of construction of subways would be so great as to render electric lighting or telephone work worse than unremunerative. The location of subscribers and users of telephones and electric lights are apt to change from time to time or from year to year, and this is particularly the case in the smaller towns. Oftentimes the different users are at considerable distances apart, and changes of location often would involve the giving up of portions of a subway or underground wire system, and would in this way lead to greater losses of capital. In the denser part of cities this objection does not hold good, because of an average sufficiency of users or consumers in such districts.

Oftentimes, in order to make a business a success, even in cities of dense population, it would be necessary for an electric light company to secure contracts for a period of years, as in this way only could it be guaranteed against loss in the installation of a system of wiring, involving the introduction of underground lines which, to be placed, would require the digging up of the streets, etc.

I am, however, heartily in accord with any measure which does not deal with this case of overhead wires blindly, but takes up the question in a fair-minded spirit, with a clear-sighted judgment of the difficulties of the undertaking. A continued experience tends to confirm me in the opinion that the proper way to deal with the question is to first dispose of those wires which can be buried without detriment and without prohibitive cost, which action would be followed by the gradual elimination of others wherever it is feasible and where the circumstances are such that this can be done without destruction of business interests involved. A plan of reorganization of the wiring under strict rules as suggested above would, I think, suffice for the remainder of the overhead work.

When this is done our cities would be free from the immense tangle of wires covering the streets and buildings, passing from point to point in every conceivable direction, vertically, horizontally and in every other way, which wires have been installed at the caprice of linemen whose only desire has been to get through their task as quickly as possible, and who in fact may have been urged to work in this manner by their employers.

ELIHU THOMSON.

Mr. T. Carpenter Smith then offered the following resolution :—

"*Resolved*, That the thanks of this association be tendered to the committee on Underground Wires for its endeavors, and the chair continue the committee and add to it Mr. Sunny, Mr. Sperry and Professor Barrett, with a view of obtaining further information, and that the sense of the association is, that it is not yet in a position to make any recommendation for or against the placing of arc light circuits of over one thousand volts potential in underground conductors. The resolution was seconded by Mr. Ecclesine.

Mr. Cooper offered a substitute as follows :—

The National Electric Light Association does not feel that the experience of which it has knowledge is of such a nature as to justify it in believing that any practical commercial method of putting high tension arc light wires carrying a current of over a thousand volts underground has been brought to its attention. The substitute was seconded.

Dr. Moses—Seven companies have replied to these inquiries. The fact is that only one city in the country has looked into this thing carefully. In view of these facts I think it would be better for us to stay any action on this subject till we have more experience. When you are quite sure that you have a system by which electric light wires can be buried, then put them down.

Mr. Morrison—It is perhaps unfortunate that so few experiments have been made in underground lines by those engaged in the electric lighting business. I regret the personal turn that these discussions have taken, but I believe that this is one of the most important subjects which we are called upon to face, and that we cannot keep it down. I think the convention owes a debt of gratitude to the gentlemen who have composed this committee and have done the best they could. Mr. Smith, of Philadelphia, who always brings to every subject he considers a degree of intelligence not surpassed by any member of this convention, has given you a full and broad statement from his standpoint, and that is the standpoint of experience. There is, however, a point in his statement which needs to be carefully considered. He said he had had no experience with high tension arc lights. The experience given by Mr. Smith, while it is good as far as it goes, does not cover the domain in which many in this association have invested their money, and to whom capitalists are looking for a return of the money invested. A subject of this kind cannot be fairly considered nor properly passed upon in a day, much less in the time allowed us to-day. This convention is banded together for the purpose of obtaining from year to year such information as the experience of its members can suggest. We are not expected to frame perfect laws or give information which is infallible. I think it was in 1874 or 1875 that I was superintendent of the fire alarm telegraph of Baltimore. I was directed by the council of that city to report upon the feasibility and probable cost of placing the wires underground. I had correspondence with every country on the face of the globe where underground wires had been used. An exhaustive report was compiled. I was able to report that it was perfectly feasible to place such wires underground, and the cost at which that work could be done at that time in Baltimore was named. The conditions which govern the laying of telegraph and telephone wires and those which govern electric lighting are entirely different; but no one has ever heard me say that it is not feasible to put high tension electric light wires underground. On the fifth day of the current month I received a letter from the editor of the Kansas City *Globe*, asking me whether, in my opinion, any satisfactory system had been invented, and whether arc electric lights could be placed in a subway with telegraph and telephone wires, also if high pressure electric light companies would be compelled to discontine business if the underground wire law went into effect. To those questions I made the following reply :—

BALTIMORE, Feb. 11.

It is, in my judgment, possible to construct a subway and to make it available for high as well as low tension systems of electric lighting. Such a subway, however, has never been constructed in this country. The efforts in that direction, notably in New York and Chicago, have succeeded only in crippling the electric light service, preventing the general public from reaping so fully the benefit from it as when the lines are permitted to be used overhead. The demand for subway construction comes, in a general way, from legislatures and citizens who know little or nothing about its requirements or defects. Intelligent legislation cannot be had unless the legislators possess this knowledge or take sufficient time and make sufficient expenditure of money to possess it. For this reason all experiments in this direction should be made at the expense of those desiring it. It is, therefore, my opinion that all subway construction should be done at the expense of the city or state, and when by them completed should be submitted to competent judges as to their availability for the purposes intended. Then introduce the wires in a limited way, that experience may prove the correctness of the system, after which order private companies to place their wires in each conduit, charging sufficient rental for the same to cover cost of maintenance. I say cost of maintenance, not any part of the cost of construction. It is my opinion that neither municipal nor state governments should invade the domain of private enterprise for the purpose of making profit. The citizen has greater stake in the untrammeled use for electricity for light and power than he has in the investment necessary to take the current underground. If this course is adopted by the legislature of Missouri or any other state, it will not "cripple the arc light companies using high pressure," nor will it "lead to the abandonment of these enterprises."

J. F. MORRISON.

That about covers the ground from my standpoint. I have been familiar with every effort in this direction, and consider the work done in Chicago as perhaps the most intelligent of any experiments in the United States. The result is told by Mr. Sunny. He has shown you that the subway system in Chicago is not perfect, and the tremendous cost of it. I believe those evils can be remedied and some plan found by which the lines may be carried underground. Until that time comes, no body of men, state legislatures or others, have a right to put their hands in your pockets or mine and take from us the result of our labor and invest it in a plan which lessens their taxation and imposes a double burden upon us.

I look to such men as Professor Barrett and Mr. Johnstone and the men who are engaged in the manufacture of insulated cables for the solution of this question.

The question upon the resolution of Mr. Cooper was then put, and a vote taken by roll call.

During the calling of the roll, when Mr. DeCamp's name was called, a separate vote was recorded for him as the representative of four different companies. The question whether he had the right to more than one vote provoked some discussion, and was settled by Mr. DeCamp withdrawing three votes.

The substitute was lost. The question recurring upon the original resolution of Mr. Smith, Mr. DeCamp offered an amendment, adding to the resolution the following words :—

"*Provided*, however, that the passage of this resolution shall be without prejudice to the resolution passed at the meeting held in New York in August last, until a further report is made by that committee."

The amendment was lost by a vote of 31 to 37.

Mr. G. H. Roe, of San Francisco, offered the following substitute :—

"*Resolved*, That while the appliances and devices for operating electric light wires underground are being continually improved, and promise ultimately to render practical the operating of all electric light wires underground, they have not yet reached such a degree of perfection as would justify this convention in declaring itself in favor of underground wires for central station arc lighting."

The amendment was lost by a vote of 31 to 39.

Mr. Morrison moved that the resolution be laid on the table and made a special order for 12 o'clock, February 21. The motion was carried.

The convention then adjourned until the following day, Thursday, at 9.30 A. M.

THURSDAY'S PROCEEDINGS.

The secretary read a letter addressed to President Duncan by David J. Harris, manager of the electrical exhibition of the St. Louis Exposition and Music Hall Association, stating that an extensive general exhibition would be held at St. Louis, commencing on or before September 4, 1889, continuing for a period

of six weeks. It was stated that it was intended to make the electrical exhibition the finest ever held in the country. The letter continued :

No charge will be made for power or space to exhibitors who are members of your association, and ample accommodations will be made for such exhibits. It is expected that articles for this exhibition will be shipped to St. Louis and returned for one half the usual rates. The St. Louis Exposition and Music Hall Association cordially invite the National Electric Light Association to meet at St. Louis during the time of this electrical exhibition. The exhibition building occupies four large blocks, cost $700,000, and contains two halls, the larger having a seating capacity for 5,000 persons. The smaller hall, known as Entertainment Hall, which is fitted in the finest style, will be placed at your disposal, in which to hold your convention, free of charge, including all the necessary service, light, heat, etc. Ample hotel accommodation will be provided at very reasonable rates.

The communication was received and filed.

The following gentlemen were elected to membership upon the recommendation of the Executive Committee :—E. G. Acheson, S. A. Barton, C. F. Dunderdale, H. H. Eustis, A. R. Foote, N. D. C. Hodges, W. J. Johnston, Philip Lange, George M. Phelps, R. F. Ross, C. M. Ranson, Fred. H. Whipple, David Stinton, John Kilgore, A. D. Bullock, W. A. Kreidler, J. P. Barrett, Timothy W. Sprague, G. L. Austen.

Mr. Sunny, chairman, read the report of the Executive Committee, as follows :

REPORT OF THE EXECUTIVE COMMITTEE.

At the meeting of the association held in August last at New York the following resolution was adopted :—

"*Resolved*, That this association shall hereafter have a permanent office in the city of New York, which shall be in charge of an expert electrical engineer, who shall be secretary and treasurer of the association ; that the president at once take steps to secure the services of such a person, and establish him in suitable headquarters, and with suitable facilities, in this city."

The president, acting on the instructions contained in the above resolution, appointed Allan V. Garratt, of Boston, secretary and treasurer of the association at a salary of $2,000 per year.

The Executive Committee, at a special meeting called in Pittsburgh, November 19th, unanimously ratified the appointment and indorsed the action of the president. The Executive Committee has examined the financial report made by the secretary, and the work that he has been able to accomplish during the past four months. It is entirely satisfied with the results that have been obtained, and unanimously recommends that the office in New York be continued for a further term of six months. While the committee is not unanimous in the opinion that an office in New York can be maintained unless the membership is very largely increased, it is entirely willing to have the experiment tried for six months more, and is very hopeful that the secretary will be able to make the office so successful as to justify its continuance indefinitely. On the occasion of this convention the Executive Committee has striven, at the suggestion of a number of people, to make an electrical exhibit that would represent as fully as possible the electric light and power service.

As has no doubt been observed, many of the manufacturers have gone to a large expense to make the display both complete and instructive. It was decided that in justice to the exhibitors a larger attendance of persons to view the exhibit than was represented in the association ought to be assured, and the committee, therefore, has sent out about 50,000 invitations, addressing them to persons connected with the management of the large industries and the educational institutions. So far the attendance has been of a character that is encouraging both to the committee and the exhibitors, and everything points to the accomplishment of the result aimed at, namely, the educating of the general public in the progress in electrical development.

Mr. A. F. Mason, of Boston—The report recites that at a meeting in Pittsburgh the action of the president was confirmed, and names a date somewhat subsequent to the opening of the office in New York. If I am at liberty to, I would like to know, whether the provision was made by the Executive Committee for the payment of the salary of the secretary from the time when these quarters were opened.

Mr. Sunny : Yes, sir, it was.

The report of the Executive Committee was adopted.

Mr. Steuart—It is necessary for us to-day to elect officers for the ensuing year, and I, therefore, move that the house now go into a committee of the whole for the purpose of nominating officers.

The motion was carried, and the president appointed Mr. Steuart chairman of the committee.

COMMITTEE OF THE WHOLE—NOMINATIONS.

The Chairman—The first thing to be done in preparation of the work of the Committee of the Whole, is to request all those who are not active voting members of the association to retire from the room. It is necessary to do this in order that we may transact this business. It has to be done with closed doors ; we shall be very glad to see all visitors as soon as the committee rises.

Mr. W. S. Hine, of New York—I beg to nominate for president of the National Electric Light Association for the ensuing term, Samuel A. Duncan, of Pittsburgh.

The nomination was seconded.

Mr. Duncan—Mr. Chairman, while I feel grateful for the compliment paid in the nomination, I rise to decline most emphatically. You have honored me with the position of president for the term of one year. I feel that the action of this association to-day in the report, which has been made to it by its Executive Committee, showing the financial status and condition of the treasury of the association and the work accomplished in a very short space of time, is such that it needs no word from me to justify the wisdom of the association in establishing a permanent headquarters in charge of an electrical engineer as secretary and treasurer. I have no personal ambition to gratify; I have no enemies whom I desire to punish and no friends to reward. My desire has been from the very first to put this association upon a higher plane, and believing that that was the proper way and the only way by which this association could come to a higher and better standing, I suggested that policy. Whether it is right or wrong, time will develop, and I have no doubt that in the hands of the gentleman, whoever he may be, whom you select for your president, an honest, fair, straightforward trial of this officer will be had, and whether it shall demonstrate the wisdom or unwisdom of the course, the trial will vindicate the effort of the association to do what it started out to do. Thanking you for all the courtesies you have extended the chair, I decline the nomination.

Mr. M. J. Perry, of Providence—Four years ago, amid much boisterous tumult without and some little trouble within, in this city, in the month of February, was born the National Electric Light Association. Present at that time, earnestly working, willing ever to put aside anything that might affect him personally for the good of the association, was a gentleman who is with us to-day, and has been with us at every meeting of the association, one who has been careful and thorough in all investigations, conservative in all his conclusions, honest and conscientious in all his convictions—that gentleman is known to you all—I nominate him for president of this association for the ensuing year—Edwin R. Weeks, of Kansas City.

Mr. Weeks's nomination was heartily seconded by Mr. De Camp, Dr. Moses and Mr. E. A. Maher.

Nominations for the presidency were then closed.

Mr. Cooper—For first vice-president of this association I have to propose to this association the name of a gentleman who has long been associated with it in all its work. I nominate Mr. A. J. De Camp, of Philadelphia. Mr. De Camp's nomination was seconded cordially by Messrs. Cooper, Ridlon, Cram, Beidler and Mason.

G. A. Redman, of Rochester, nominated Mr. E. A. Maher, of Albany, for second vice-president, and was seconded by Mr. C. C. Curtiss, of Cleveland.

H. M. Daggett, of Attleboro, Mass.—I would like to submit a list for members of the Executive Committee of the ensuing year. I would nominate B. Rhodes, of Niagara Falls ; B. E. Sunny, of Chicago ; George A. Redman, of Rochester ; C. R. Huntley, of Buffalo ; Dr. Otto A. Moses, of New York ; E. T. Lynch, Jr., of New York ; P. H. Alexander, of Boston ; J. F. Morrison, of Baltimore ; and T. Carpenter Smith, of Philadelphia.

Mr. C. A. Brown, of Chicago—I would move that the same ticket be nominated, with the substitution for the name of Mr. Sunny, of Charles R. Faben, of Toledo. In doing this I want to state that my object is to have the Executive Committee consist entirely of central station operating representatives, or at least of those men representing current companies, so-called. We should exclude from the Executive Committee all who are engaged in the supply business or in the manufacturing business. Another reason for substituting Mr. Faben's name for that of Mr. Sunny is that Mr. Faben not only has a large electric light plant, but also is a representative gas man. The gas men have on many occasions given membership to electric light men. I do not think the electric light associations have extended equal courtesies to the gas men. Mr. Faben is not known to most of us, I presume, but whoever does know him will know him to be a whole-souled genial man. He expected to be here at this convention, and hoped to be, but sent his regrets. He is a member of the association, and I hope that his name will be placed on the Executive Committee.

Dr. Moses—Mr. Brown has spoken of the necessity of the Executive Committee being composed of men who represent central stations. That has been in my mind. I, myself, do not represent such an institution, and yet I think that this association should be composed, not only of men who represent stations, but all other interests in which electricity plays an important part. Nevertheless, it is my sincere conviction that the ultimate success of this association depends upon its guidance by those who are interested, and who represent central station lighting. Now, this association, as I understand it, has been formed for the purpose of bringing together those employed in central station lighting and other branches of electricity, and those who furnish supplies. It has been successfully done, and I hope that both of these inter-

ests will recognize at once their due position. I, myself, come in somewhat in an intermediate capacity. If it is the opinion of this convention that only one of these interests should be represented upon the Executive Committee, I feel as if I should respectfully withdraw my name from it.

T. Carpenter Smith, Philadelphia—I feel a little modesty in rising to speak on a nomination for the Executive Committee, having myself been nominated, but I think it due to the convention to state what I think would be for its best interest, and what I think we will all of us realize in a short time, and that is, the extreme value of Mr. Sunny as a member of the Executive Committee [applause].

Mr. S. A. Duncan—I nominate Mr. F. A. Cheney, of Elmira, N. Y., as a member of the Executive Committee.

Mr. Morrison—I cannot sit silent and see the possibility of having drift from your active service in the cause of the association, a man so conspicuous for his interest in all electric lighting matters as Mr. B. E. Sunny. The perfect appointments of this convention, the vast labor necessary to bring about the condition which you see before you, and all that appertains to it, while due credit must be given to all the electrical people of Chicago, including the chief of the municipal electrical department, yet he with whom we have been brought directly in contact, and with whom we have served on the same committee, has demonstrated his great fitness for the place, to which he has been nominated. The objection made by Mr. Brown is in the main a valid one, and yet, on the Executive Committee, Mr. Sunny is the only exponent of a system that sooner or later we will be compelled to face; that at each convention will be brought up before you, and that I hope to see settled; that some provision will be made to place every electric wire under the surface of the ground. Mr. Sunny has had the handling of an underground plant in Chicago. I, for one, believe in going to the shop to get shop information. I believe that, to have the best results, this association must be brought in touch with those who handle the specialties by which they carry on their business. I believe that the manufacturers of apparatus, the manufacturer of cables and insulated wires, and those who are spending their time and their money in endeavors to bring about the best plans of placing wires underground, are all valuable aids and adjuncts to this association, and without them, your meetings twice a year would be comparatively valueless.

Mr. Mason—The reason stated here for the motion to drop Mr. Sunny and to introduce another name is an outrage to one-half the members; men who do not want any office, but who are told substantially that they can pay their dues and exhibit their goods, but they must understand that they are not of the association, that they are an outside element. If this association is an electric light association, such language ought not to be permitted. If this association is an association of central station plants, let it be so, and be called so. I earnestly hope that Mr. Sunny's name will be retained on the committee.

Mr. Brown—In making the amendment which I offered, I had several reasons why it was more proper, as I thought, for me to make that motion than for any one else to make it; and in stating those reasons I think I will explain to Dr. Mason what, it seems, has rather touched him, that I am not a central station man. I am not a man engaged exclusively in selling electric light lamps, but the business of the company which I represent covers not only manufacturing electric light apparatus, but also dealing in supplies. Therefore, I thought that it was particularly appropriate that the expression of opinion which I have heard frequently—not on the floor of this convention, but outside—should come from a man who represented various interests. Another reason why I thought that such a motion was proper as coming from me, was because, I am personally acquainted with Mr. Sunny, and it would be understood by every one, I think, that there is no personal objection in my mind to Mr. Sunny. It was simply a matter of policy that I wanted to introduce here. Another reason was, that I was on the nominating committee at New York; I was chairman of that committee, and it was my own motion that Mr. Sunny should be appointed on the Executive Committee and made the chairman of that committee, a position which he has filled to the satisfaction of every one. Another reason was that, in a conversation which Mr. Sunny recently had with me, he said his determination—not his desire, but his determination—was never to serve on the Executive Committee again, and rather laid blame on me for getting him into the position that he had occupied so far. I make these remarks in explanation of my amendment to the original motion.

General discussion followed, during the course of which Mr. Brown withdrew Mr. Faben's name.

The question being on the nomination of Mr. F. A. Cheney for a place on the Executive Committee, the nomination was lost by a vote.

A resolution to adopt the nominations of members of the Executive Committee as first made, was then put and carried unanimously.

The Committee of the Whole then rose, the president resumed the chair, and the association received the committee's report on nominations as follows:—

President: E. R. Weeks, of Kansas City.
1st Vice-President: A. J. De Camp, of Philadelphia.
2d Vice-President: E. A. Maher, of Albany, N. Y.
Executive Committee: B. Rhodes, of Niagara Falls; B. E. Sunny, of Chicago; C. R. Huntley, of Buffalo; Dr. O. A. Moses, of New York; E. T. Lynch, Jr., of New York; P. H. Alexander, of New York; J. F. Morrison, of Baltimore; T. Carpenter Smith, of Philadelphia.

The report of the Committee of the Whole was postponed.

The Chairman—The next business, according to the special order, is the resolution of Mr. Smith, namely:—

"That the thanks of the association be extended to the committee for its endeavors, and that the chair continue the committee on Conduits and Conductors, and add to it, Mr. Sunny, Mr. Sperry and Professor Barrett, with a view to obtain further information, and that the sense of this association is that, it is not yet in a position to make any recommendation for or against the placing of arc light circuits of over 1,000 volts potential on underground conductors."

Mr. T. C. Smith—I rise to speak upon this motion, because, I think it right to explain exactly what I wish to accomplish by that motion. I am afraid that I have been misunderstood by the very men whom I wish to benefit—the central station men. I have already had brought to my attention very forcibly within the last year that this association has been getting the name of a packed body of men to oppose underground wires. The moment that attitude is taken by the public, that moment the central station men find this association of no earthly use to them, but rather a detriment. I introduced that resolution that this convention of this National Electric Light Association might come before the public as a body of men who were willing to consider any question fairly and justly, to examine into it with all the skill and knowledge at their command. I had hoped that the report of this committee coming before us showing the distinct disadvantages of underground wires would enable us to say to the public, "Gentlemen, we are doing the best we can to gain information, and we are honest minded and upright enough to tell you as to the report handed in directly against underground wires that we are not yet in a position to say anything for or against it." I made the resolution in all honesty of purpose, and I am very sorry to say that I have since learned that it has been used to foment trouble between the central station men, and the supply men. I introduced the resolution for the best good, as it seemed to me, of the National Electric Light Association. I ask the unanimous consent of the convention to withdraw that motion, and I would ask that some central station man who is distinctively a central station man should present it to the convention.

Leave was unanimously given to Mr. Smith to withdraw his motion.

Mr. Morrison—In order to dispose of this matter in the way which will bring the best results to the National Electric Light Association, I beg to offer the following resolution:—

"*Resolved*, That the report of the Committee on Conduits and Conductors be recommitted to that committee, and that Messrs. Sperry, Barrett and Sunny be added to the committee, and that the committee be continued.

The motion was carried unanimously.

The report of the Committee of the Whole on nominations of officers was unanimously adopted, and on motion of Mr. Morrison, the secretary was authorized to cast the ballot of the association for the list of officers and Executive Committee as reported by the Committee of the Whole.

Mr. Morrison moved that the next place of meeting be Niagara Falls, at a time in August which shall be designated by the Executive Committee.

The motion of Mr. Morrison was adopted unanimously.

Niagara Falls selected as the next place of meeting.

Mr. S. E. Barton, of Boston, then read a paper on "Electric Light Stations as Fire Risks." (See page 94.)

Mr. Morrison—I want to call attention to that part of this able paper in which reference is made to the lamentable condition of many of the electric light stations of this country, to the occupancy by electric light companies of old tumbled down buildings. This is doing more harm to the electric light business than all its antagonists put together. The one declaration made in that paper, that the insurance companies of New England have been compelled to abandon the risk of electric light stations, is a sufficient warning to all those about to engage in that business; that the only proper course to pursue is to erect substantial stations under intelligent supervision, and that a law ought to be passed in each state, where electric lighting is proposed, placing such construction under the supervision of the government.

Mr. Barton—It is a pity to see what I believe to be one of the safest of risks that we can have at the present time, through no reasonable excuse whatever, in such a condition that insurance companies will not touch them as a general rule. I believe that in our business generally about 25 per cent. of the loss may be charged to what is known with us as moral hazard. I hold that this 25 per cent. should be eliminated from the electric lighting

hazard; there is no moral hazard. Therefore, I say when we can have a class of risks with that one risk entirely wiped out, it does seem a shame that we cannot have the class so raised as to make it desirable for insurance companies at low rates. The matter is receiving considerable attention now in New England, and only recently, the electric light committee, of which I am the chairman, has been asked by the New England Insurance Exchange to formulate a schedule for the purpose of making tariff rates upon central stations. Heretofore it has been done by the various committees, and has been out of the control of the electric lighting committee. They have been rated at what we call the flat method of rating without any regard to the real merits or demerits of the risk. We are now undertaking to formulate a schedule in which we shall assume a standard model risk at a very low rate. We shall then add for any deficiency a special charge—for those features which we believe contribute to making a central station a poor risk, and which can be eliminated by changing, and it will be largely in the method of construction, internal as well as external, of modern fire appliances and of the arranging of switchboards and things of that kind. We hope in a very short time to get a schedule formulated, whereby electric light people can have some idea of what we, as insurance men, think should be done in order to improve your risks, and that will be put into general operation in New England, and I hope it will spread. I know for certain that New York state and that the New York city associations will adopt it as soon as we have issued it, and therefore it looks as though the insurance of central stations in the eastern part of the country was in a fair way to reach some sort of a solution; but still it lies in your hand, gentlemen, to make it what it should be.

Dr. Moses—I have in my hand a pamphlet that has been sent to me, and I understand it has been extensively distributed throughout the United States. I will not comment on it, beyond merely reading its title, "The Comparative Danger to Life of the Alternating and Continuous Electric Currents." I have read this, but I will not lay before you the criticisms that this gentleman makes before the body now assembled. Those criticisms are not worthy of notice, but I have a resolution here which I think can express our views and which I would like to see adopted:

"WHEREAS, A certain individual, in order to gratify a personal resentment, has, in exaggerating the dangers of electric currents, striven to influence legislation so as to cause the introduction of electricity in the form of alternating current as a means for the infliction of death on condemned criminals, therefore, be it

"*Resolved*, That the National Electric Light Association earnestly protests against those efforts, and unanimously resolves that the members of this body decline to allow any electric current under their control to be used for ignoble purposes."

Mr. Phelps—If in order, I move that the resolution be laid on the table. I think we had better ignore the pamphlet entirely.

Mr. Steuart—I have to offer a resolution which I am sure you will all accord with, and that is, that we tender to Mr. Barton the thanks of the association for the very excellent paper he has read for us, and that it be accepted and placed upon file among the records of the association.

Mr. Phelps—I withdraw my motion and will renew it afterwards.

Dr. Moses—I beg to suspend the resolution I offered in order to pass the resolution by Mr. Steuart, in which I most heartily concur.

The resolution of thanks to Mr. Barton was unanimously adopted.

Mr. Phelps—I renew my motion to lay Dr. Moses's resolution on the table. My opinion is that it would be very unwise for us to pass this resolution. We probably could not better please the author of that book than by passing the resolution. If we disapprove of it we can do it best by silence. That is my view, but I will not argue it now, because you all want to go to dinner.

Dr. Moses—I will beg to state for that reason I did not state the name of the individual, but the efforts are there. It is quite unnecessary for us to know the name of the man who shoots an arrow at us in the dark if it hits us.

Mr. Phelps—I think it would be better to withdraw the whole matter.

The motion to lay on the table was put and lost, and Dr. Moses's resolution was adopted.

The convention then took a recess until 2 o'clock P. M.

THURSDAY AFTERNOON.

The President.—The first business in order this afternoon is the report of the committee on the New England Exchange and the discussion of Mr. Barton's paper on insurance.

Mr. P. H. Alexander.—I am not the chairman of the committee, but I was requested by the chairman to bring before you this matter of the New England Electric Exchange. I have not prepared a written report, but as the secretary of the exchange wisely put in some numbers of its paper which contains a stenographic report of the proceedings, I may, with its aid, make the object of the exchange well understood.

In March of last year there seemed to be a great deal of dissatisfaction expressed as to certain insurance rules pertaining to wiring, and in order to see how the electrical fraternity stood on this matter I prepared a circular which, in common with other gentlemen in the business, I have sent around to every station superintendent and station company. The circular reads as follows:—

Comments having been made by electric light people regarding the rules issued by the Insurance Exchange for regulating light installations, it seems desirable that the representatives of electric light companies and superintendents of central stations should meet the electric light committee of the Insurance Exchange and their inspectors, to talk over equitable means for harmonizing the object of insurance inspection and the effect of installation of electric light plant.

The circular then goes on to call a meeting at a certain time. There was quite a large attendance at the meeting which followed, about sixty or seventy gentlemen being present. A number of electrical matters were discussed, and it was finally proposed to form an organization to be called the New England Electric Exchange, which should be, so to say, a mediator between what then seemed to be conflicting interests. The organization was completed by the choice of officers, and right here let me say that in that organization only manufacturing companies and electric light companies were to be admitted to membership. The call read as follows:—

Every one actually engaged in manufacturing or installing electric light and electric power apparatus, or in operating commercially an electric light or power plant, will be eligible to membership of the exchange.

This meeting was held on the 2d day of April, and a constitution was adopted, and also a plan of licensing. The exchange took the ground that the insurance companies could not help reduce insurance where electric light installations were made perfect, and you have heard Mr. Barton's paper this morning, which states that he acquiesced in that. We took the ground that electric light was the least dangerous artificial illuminant, but we took the ground that electric light plants should be perfectly well installed, and therefore we proposed to license—and we have done so since—employés of electric light companies operating electric light, and employés of wiring companies. The result soon shows itself. In less than six months from the time that the organization was started, the insurance companies of their own accord made a reduction in insurance rates on all buildings and manufacturing establishments where electricity was used as the only illuminant, a reduction of 10 per cent. on incandescent, and 5 per cent. on arc light plants. The prime object always has been to look for good work. Manufacturing companies and operating companies alike had a common interest to have good work done. Lately some trouble arose in the city of Boston regarding fires that were said to have occurred there from electric wires, and the board of underwriters of the city of Boston proposed to adopt more stringent rules. We invited them to meet with us and the tariff committee of the Boston Fire Underwriters' Union and the electric light committee of the New England Exchange and the inspectors of the Insurance Exchange, and, in common with them, we discussed this matter, and as a consequence this circular was issued Feb. 1.

To Electric Light and Wiring Companies:

It has been decided by the Boston Fire Underwriters' Union that on and after March 1, 1889, they will not approve underwriters' wire for electric light wiring in any manner inside of buildings. Moisture-proof and water-proof wire must be used. All loops, or drops, from poles or other outside structures, to and into buildings, must also be of a heavy moisture-proof insulation. It must first be submitted to the electrical inspector for his approval. This rule applies to all new work, also to any change made in old work. Parties who have made contracts for wiring calling for underwriters' wire, which contracts will not be completed before March 1, 1889, must send a written notice to the electrical inspector of the Boston Fire Underwriters' Union. If such notice is not given, the work will not be approved under any circumstances. Any contract made subsequent to this notice, and not strictly complying with these rules, will not be approved.

At a meeting of the Underwriters' committee, held Jan. 28, 1889, it was voted that on and after May 1, 1889, all electric lighting and wiring companies' men, who are in any way responsible for any of the wiring, running of dynamos, or care and management of batteries for electric lighting, must hold a license from the New England Electric Exchange. This rule applies to isolated plants and central stations alike, and is imperative. No exception to it will be made.

OSBORNE HOWES, JR., Secretary.

I read this to you to show how harmonious are our relations now, that a year ago seemed to be antagonistic. The plan of licensing has further been approved since by the legislature, who have incorporated this exchange and given it power to grant licenses. In order to promote ambition in excellence of workmanship and to extend the knowledge among men practically engaged in installing and operating electrical plants, and thus make it an object for fire underwriters to recommend the introduction of electricity in preference to other means of producing artificial light and power, the New England Electric Exchange will issue licenses of five classes, each class representing a certain extent of qualification. First-class licenses are issued only to persons fully competent to install and operate any electric light or electric power plant. The applicant for a first-class license must be able to make working plans for central stations and for isolated installations, must have a general knowledge of the construction of dynamo-electric machines, and the electrical appliances necessary for electric light and electric power installations, a general knowledge of the principles, construction and installation of secondary or storage batteries, a thorough knowledge of the insurance rules pertaining to the business, a specific knowledge of the system operated by the applicant, and a thorough knowledge of the calculations necessary for and the rules governing electric wiring, and be able to make complete wiring plans. From this class

we go down to those requiring less and less knowledge to men who are not competent to do the electric work. Fifth-class licenses are issued to persons competent only to operate electric machinery, and who are not competent to do electric wiring. The applicant for a fifth-class license must have a general knowledge of the operation of the particular electric light or electric power machinery it is desired to operate, and a thorough knowledge of the insurance rules pertaining thereto. "Who were your examiners and who examined your examiners?" as one man put it to me. Well, we have in New England a good many good electrical men. We had Mr. Anthony and Mr. Hill, of Boston, on practical work. We generally take three men to work together, two of whom would be good practical men and one having a good knowledge of theory. These gentlemen have to serve right along, without pay. I want to say that in order to make this a success it was necessary for about twenty-five of us to give half a day each week to this business exclusively—to devote themselves to this matter at a loss; but they have done it. We have now six examining boards composed of three each, and we have five directing boards that meet every Monday. Every safeguard was put, however, around the issuing of licenses. These examiners would examine the applicant who made application for a certain class. How few of them obtained it the last official report, which dates now some months back, will show. I find that forty-three men applied for first class license and only twenty-six obtained it; of forty-five who applied for second-class only thirty-one were successful, while forty-two men who had applied for higher class licenses received only a fourth class. But they were quite satisfied, and we have a great many letters from them saying, "We simply go ahead and will try again." They have in several cases brought to the second examination a great deal more knowledge, having something to look forward to and to attain. After the examiners have gone through and made their minutes of the examination, they send their report to the board of directors, who weigh the matter carefully and either send the report back if not in accordance with rules laid down here or accept it. Before issuing these licenses each examiner has to sign the certificate that is issued. The president and secretary have to sign the certificate, and then once more we send it to the insurance inspector of that district, who comes in personal contact with these men, and who can tell us if, while they may have a knowledge of the business, they may be careless in carrying out their work. We have also a clause by which we can revoke any license that has been given to a man who proves incompetent afterward or careless in his work. Now, your resolution last summer asked this committee to recommend to the National Electric Light Association what means should be taken to attain the same object. I have given this matter thought only a couple of days, but I cannot see how the National Electric association can establish a plan unless they divide the United States up into sub-districts or recommend state organizations. I want to say before I sit down that Mr. Barton's paper this morning, as well as the remarks I have made, would probably be best supplemented if the president would grant the New England insurance inspectors who are present here, but not members, the privilege of the floor.

The Chairman—We shall be glad to hear from Captain Brophy.

Captain Brophy—If the New England Electric Exchange fulfills its promise half as well as I hope it will, the office of insurance inspector will be no longer necessary. The insurance people of New England perhaps have taken a more intelligent view of the electric light matter than most any other body of insurance men. There is no antagonism between the two bodies, but the insurance men stand sadly in need of enlightenment in regard to many points of electric lighting. When we have competent men in every station in New England ready and willing and taking a pride in doing their work as they ought to do it, the sensational newspaper of the day will have one less theme. Now, it is very difficult to secure a fair share of insurance on the best-equipped electric light stations in the best companies. In New England we have had scarcely any loss to speak of, when the amount of property invested in electric light stations is taken into consideration; but we are met with the fact, I suppose, that they do have severe losses outside of that territory. We have just now blocked out a schedule of rating for electric light companies, and I trust that this organization will assist us a little. All now that is required of you gentlemen is to do what you know how to do, and see that it is done—to make fires caused by electric lights or electric light wires so scarce that they will hardly ever be heard of. I wish to correct one statement made here yesterday which should not go abroad, because it is not strictly proved. It was true that a little while ago the insurance people of Boston were somewhat agitated over the frequency, as they thought, of small fires in that city, caused, or said to be caused, by electric light wires, or by electric lights. I regret to say that this feeling in the breasts of insurance men was largely engendered by electric light men themselves. It will not do for you to run down or decry your opponents or competitors, as it will appear to the average insurance man that all systems of electric lighting are unsafe. Bear in mind that when you make them believe that one system, because it is not the one that you are dealing in, is unsafe, they naturally conclude that the same rule applies to all. Now, that was fomented in that way. It was stated here that every one of these fires was caused by underground wires. That is not true. The fires in New England, unfrequent as they have been, have not been confined to any one particular system of electric lighting; they are equally distributed among different kinds, or among different systems; but happily they have been so few that very little or few losses have had to be paid.

After remarks by Mr. Killicut, of Boston, on the same subject, on motion of Mr. Morrison, the report of the committee on New England Electric Exchange was accepted, and the committee continued. The thanks of this convention were extended to Captain Brophy and Mr. Killicut.

Mr. C. H. Rudd then read a paper on "Disruptive Discharges in Lead Cables." (See page 92.)

Mr. Acheson—Mr. Rudd has given me much pleasure by the paper he has prepared. My original experimental work was done with the object of eliciting replies and drawing others into this work—a work that must be done by somebody, and a work that I have but few facilities for doing. But I have here a few notes of some work that I have done during the last week. There were two questions, I believe, which Mr. Rudd said that the matter turned on—either I was demonstrating or had discovered a new principle, or else it was all wrong. I do not think I discovered a new principle and I do not think it is all wrong; but he seems to think that I have assumed an increase of energy, owing to the existence of the cable. That is not exactly the case. We have though, owing to the fact that the cable is there, an energy on hand that is not contained in the dynamic current, and it is that that produces our discharge; and following that up in a very limited way, I find for instance, from experiments, that the time necessary for the formation of an induced current on opening a primary—the induced current being a secondary—is the twenty-five hundred thousandth part of a second; that a current is of quite sufficient length and more than sufficient to produce a spark. The time necessary for the spark is about the eight-millionth part of one second. Now we have here the amount of energy contained in or represented by the dynamic current in two hundred feet of a No. 6 Brown & Sharpe wire conductor, when conveying a current of two amperes. That will have for each second of time, passing under that wire, an energy equal to eight and two-tenths joules, and the amount of energy that may be withdrawn from such a conductor under such conditions in the space of a twenty-five hundred thousandth of a second, or the time occupied by the induced current will be two five-hundred-thousands of a joule. Now the amount that can be withdrawn in an interval of time equal to twenty-five hundred-thousandths of a second will be four-tenths of a joule. Now the energy contained in the same sized cable under similar conditions and operated by two thousand volts of current, the energy there will be equal to four one-hundredths of a joule, or about twenty times the amount of energy that can be withdrawn from the same length of cable, owing to the existence of a dynamic current in the cable. Mr. Rudd assumes that I have supposed an increase of energy or a building up. It is a building up, or rather it is a condensation, you may term it, owing to that capacity, and it enables us to do about twenty times that work. Some experiments I made were in relation to the time necessary for a discharge on the more remote parts of the cable. I wanted to learn how the distance from the terminal would effect this discharge, and although I have lost my notes, I have roughly jotted down some of the data from memory. My experiments were made with wire No. 18, Brown & Sharpe. There were fifteen feet of wire through which I could discharge a current that was held in a jar having a capacity of twenty-five ten-thousandths of a microfarad, and charged up to its potential, so that it would discharge through two hundred and eighty-six thousandths of an inch. With that amount of energy discharged through that wire I produced an induced current in a parallel wire and used that as a means of determining the time or rather the rapidity of change in the inducing current affecting directly the electromotive force in the parallel wire. With a wire ten feet long—my parallel wire was about five feet in length—I could get a discharge between the terminals of the terminal wire of one hundred and fifty thousandths of an inch. As that wire lengthened to twenty-five feet the discharge became about seventy-five thousandths of an inch—I have forgotten exactly—and it fell to about forty thousandths at one hundred feet. From there on the curve flattened out, and at two hundred feet it had not dropped probably below thirty-five thousandths. Now, from this I rather argue that the first one hundred to one hundred and fifty feet is the portion of the cable that is going to effect this discharge. The other portions beyond that cannot deliver their energy with sufficient rapidity. It shows the necessity of the energy being delivered instantly, in a time far beyond any measurement of ours—in the eight millionths of a second. Now, if Mr. Rudd will kindly permit me to use his diagram, I would like to say something further. This is the diagram showing the apparatus first used to determine the electromotive forces of these various sections of the conductor, and also the required electromotive force with any given condenser or capacity for this discharge. Now, as I stated, my experiments

at this day were hardly begun. I had not yet learned the true cause of this, and the fact of the necessity of explaining it does not detract, I should think, from the existence of the results. They still exist, regardless of the fact of any necessary explanation which I, at that time, did not have, but which afterward has been partly shown. The length of this wire [indicating] was certainly a few inches. I have forgotton the lengths. In fact I did not at that time appreciate the necessity of measuring them, but they were probably perhaps four or five feet. Now I have just shown that five feet of wire lying parallel to a primary wire receive and induce current sufficient to discharge through fifteen one-hundredths of an inch, and we know that a current induced in a parallel wire is not as great as that induced in a primary, in case the secondary is absent. The current in the primary is the greater of the two. So that when we open this, we have here a charge in this condenser, and on opening this our electromotive force drops and the condenser will tend to discharge back [indicating]. It will induce a current here, but owing to the opening here [indicating], it has set up a self-induction at this point that will be sufficient to close across. That is a possible explanation, and it is not one that I absolutely assert is true. It is only in a condition of study with me. I am not through with it and I am glad to have the assistance of any one who is willing to join in the work.

But Mr. Rudd did not draw attention to the existence of the condenser in this diagram. He referred to the fact that opening this switch lengthens this distance. How he supposed that I in any manner attributed the opening of that and the necessary increase of this to the production of a spark, I cannot understand.

Mr. Rudd—Pardon me, Mr. Acheson, didn't you do your first work without the condenser?

Mr. Acheson—Yes, I find that I did; but I believe that I attributed that to the capacity of the circuit. I actually gave the capacity of the circuit as the four hundred thousandths part of a microfarad, and that this part, without the other condenser, was due to the capacity of the circuit. In no case did I consider it without the capacity; for, though I sometimes tried with the expectation of not getting it, I still found it in the circuit.

Mr. Rudd—I would say right here that I took the ground that if capacity was at all necessary to make the spark plain, the capacity then was a primary condition and not merely an auxiliary condition, and I understood that you examined the auxiliary effect of condensers, or the effect of the condenser upon disruptive discharge. Where a tendency to discharge already exists you desired to find out how much that was increased by the presence of the condenser.

Mr. Acheson—Of the condenser and of the energy it delivers at the disposal of the work to be done. In the paper read in New York I believe I stated that there was no time for the generation of a current in the dynamo. You had to have it on hand. As I have shown here the actual energy transmitted over your wire is but a fraction of that on hand, owing to the existence of your cable and its capacity; it is a thing you must have there to do the work with. The current passing over the wire is not sufficient to generate it.

But referring to this diagram here, Mr. Rudd simply stated the case very clearly, as I explained, I believe, from the fact that when there is a spark here, we get a spark there [indicating]. If it was understood that I stated that it was owing to the actual existence of the arc, which I may have done without intentionally doing so, I wanted to have it understood that it was due to the fact of the arcs having existed, or existing, as the case might be. It was either due to the fact of their existing and preventing the discharge passing through the arc or to the fact that they ceased to exist and there wasn't time for the circuit to close, leaving an open space prohibiting the discharge from passing in there, and consequently it passed here [indicating].

Now, I would like to state here that while I was in the early stages of these experiments, I thought that I had already at that time obtained results of value to those who were interested in underground work, and that they would be benefited by knowing of these results and profiting by them. An invitation was sent to a gentleman interested in underground matters very extensively, to come and see these experiments, in order that he personally might profit by them. That gentleman returned to his home and introduced the subject to various others, and they entered the experimental field with a decided desire, as has since developed, to obtain results contrary to those which I had obtained, and which had been offered to him gratuitously for his special benefit. This work is some of the results of it, and this is one of the experiments made at that time [referring to the diagram]. Here we have a piece of cable placed in our circuit. The experimenters have taken a condenser and connected one of the terminals to the line wire. The statement was not made as to distance between the end of this cable and the point on the line where this terminal was connected. But having done this, they obtained a spark on making a contact with the terminal and the cable, which would not surprise them, provided the distance between these points was of any value. After doing this they connected the ends and got a discharge that certainly would not have produced the beliefs or theories that I had formed. There will under certain conditions be a different value obtained, as was shown by the fact that when the cable was dry they could not get a charge of much value. When it got wet, they did get a charge of more value. When it got wet, this cable, instead of remaining a conductor simply parallel to the line wire, became more or less grounded throughout its entire length, and in place of getting your potential at any point here which is produced by the line wire, that point would be removed a certain distance. But, however that might be, your charge could be of any value governed by the distance you would carry your point back toward the machine.

Mr. Rudd—It was two or three inches.

Mr. Acheson—Then it would be dependent on that, and your grounding of the cable would throw that point back still farther.

Mr. Rudd—If you will pardon me, I think it carried it to the other side of the dynamo.

Mr. Acheson—Then you would get the entire charge of your machine in it.

Mr. Rudd—We got a very decided charge considering the resistance of the field.

Mr. Acheson—That diagram, (figure 6) is figure 5 (see pp. 93, 94), changed in its connections, and neither of them has any relation whatever to determining the value of a discharge, owing to the current condensed in the cable. In your first two hundred feet of cable, the interval of time necessary for your current to be delivered and discharged to your terminal is greater than that occupied by your spark. But then, in your first two hundred feet your energy is of greater value than that obtained in the dynamic current in a similar range of wire.

The President—I desire to take the opportunity now of formally introducing to you our new president, Mr. E. R. Weeks, of Kansas City [applause].

Mr. Weeks—I have too deep a sense of the high honor that you have conferred upon me to fail to doubt the wisdom of your choice. Although my home is very near the geographical centre, it is some thousand miles west of the electrical centre of the United States. In view of this fact, and knowing that you have many members much better qualified to fill the office of president of this association, I take your action in large part as a recognition of the great west, as a recognition of the sleepless enterprise and indomitable pluck that is rapidly converting the great American desert into green pastures, blooming orchards and fields of golden grain, and which have transformed a vast swamp into one of the world's greatest and most beautiful cities. This association now enters upon its fifth year, and while much has been accomplished under the able leaderships of Mr. Duncan and Mr. Morrison, infinitely more remains to be done. The electrical industries lead the van of human progress. In the highest sense of the word the electrical engineer of to-day is the resultant of all engineering experience, and to the engineers of the world more than to all other professions the civilization of the present age is due. Let us remember our high calling, and with one accord strive to advance the National Electric Light Association to a still higher place among the world's industrial and scientific societies. Gentlemen, in accepting the trust which you have placed in my hands, I ask you to give me your counsel, your sympathy and your most hearty support [applause].

Mr. De Camp offered a resolution as follows:—

"*Whereas*, in no state, so far as can be ascertained, are the laws properly drawn to enable municipalities to contract with incorporated companies to perform services for cities and their citizens upon a sound economical basis; be it

"*Resolved*, That a committee on state and municipal legislation be appointed, consisting of one member from each state, to operate together, to secure such legislation in each state, as may be required to enable municipalities to contract with incorporated companies to perform services for cities and their citizens, on the sound economical basis of securing to such companies an undivided demand, an unrestricted privilege and a permanent investment."

The resolution was adopted.

Mr. Mason—This calls for the appointment of a committee of one from each city. I move that that be referred to the executive committee.

The motion was carried.

The following papers were then read:

"Fuel Oil," by Mr. S. S. Leonard. (See page 95).

"Liquid Fuel," by Mr. M. J. Francisco. (See page 96.)

"Advantages of Oil as Fuel," by Mr. C. N. Ransom. (See page 98.")

Mr. Leonard—We are pioneer users of oil in the northwest. The question of insurance is the only bugbear with us at present. The other troubles we think we have overcome. As I stated, to comply with the requirements of the insurance companies would make the use of oil almost prohibitory. Mr. Francisco states that by the introduction of air pumps for creating a vacuum, making a complicated apparatus, and by the placing of your tanks fifty feet away from your building, you can use it. I believe that oil can be used under a gravity pressure with as much safety, if not more so, than by pumping it. He quotes the Springfield, O., fire as being an example of feeding by gravity. I had a short conversation with the manager of that station not long since, and I was especially interested, as just before leaving home, the insurance

agent informed me that a policy was canceled. I asked why: "They will not insure because you feed by gravity." I asked the Springfield manager what his arrangement was. He stated that his tank was underground, and also under the building; that his supply tank was above ground, holding, I think, twenty-four barrels or thereabouts. An oil pump was used to pump the oil from his tank cars into his storage tank, and also into his supply tank. The supply tank was an upright tank, and on the top of it was a man-hole, which was left open at times. The pumping of this oil stirred it up more or less, and created a great deal of gas. The gas escaped from this man-hole, and the building was filled with it. The oil, as Mr. Francisco said, overflowed and came out through this manhole. Gravity had nothing to do with it. It overflowed and ran over the floor to a lighted lantern. The only thing that surprised me was that he had not burned up long ago. He had a regular fire trap there. Now, I claim that the use of oil should not be condemned by insurance companies because one man has it put in by a very poor arrangement. We have a capacity of about 26,000 gallons in two tanks; they are eight feet in diameter and thirty feet long, placed underground, about twenty-five feet from our building, walled up on the side, imbedded in solid masonry and arched over at the top with brick. We have a space between the two tanks about six feet, giving plenty of room for a man. We have valves at the opening of the tanks where the oil is admitted to the supply pipe and can be cut off there; at the entrance to the building there is another valve where it can be cut off; as it flows along the supply pipes there is another valve before it gets into the building, making four valves before the oil reaches the burner.

Mr. Lockwood—The company which I represent in Detroit have been using crude oil since the first of July last continuously. We feed by gravity.

Now, the manager of one of the largest insurance companies came to our plant and examined it thoroughly. He was under the impression that the pressure system was the only safe one; but he changed, his mind and said that he would recommend in the future that the gravity system be employed, and with a small tank which furnished the oil limited to one barrel per boiler per hour, and that would give capacity enough.

Our plant is different in one respect from any that has been spoken of, inasmuch that the large tank, although under the ground, is within one foot of our building, and we are right in the heart of the city of Detroit. And still as close as we are to other buildings with the capacity that we have there, the insurance company only charges us 20 cents additional rate. Mr. Francisco spoke of a case where the tank had overflowed by gravity and caused a fire. If that had been arranged as we have ours arranged in Detroit, that would have been an impossibility. We feed from the large tank under the ground to the upper one by means of a pump, and the pipe is only a one-inch pipe. We have from the upper tank returning to the lower a three-inch overflow pipe, and the three-inch overflow pipe will carry more oil than the maximum capacity of the pumps. Second, if the oil is allowed to rise too high, it can do nothing more than return to the tank from which it is pumped.

We also have connected with it one other safeguard, that is, the pipe feeding the oil from the small tank to the burner is connected at the level of our floor with the overflow pipe returning to the large tank with a cock-opening valve, so, in the event of fire, if this valve is opened in less than two minutes every bit of oil in the building within the small pipes will be thrown back to the large tanks.

Mr. Francisco—I have been inspector and general agent and adjuster of insurance companies for twenty-five years. That was my business until I took up the electric light business; in fact, I am in it now. I have consulted nearly every one of the prominent companies of the country in regard to these points that I have developed in my paper. The insurance companies' managers have told me that if the electric light folks would adopt the plan I have proposed they would insure them, but if they did not, they should charge them as I have specified.

Now, Mr. Leonard's use of valves is all right. But the point comes just here. There are always a lot of fools around electric light stations, the same as everywhere else so far as fire is concerned; and your station may have forty valves, but what good would it do to men situated in the other part of the building?

In the case in Winsted, Conn., where they used petroleum oil, the station burned up awhile ago. The insurance was paid. They were burning oil at Winsted and they fixed everything up in first-class shape; they had steam pressure where they forced the oil from the vertical pipe; then they had an escape pipe for blowing out the sediment that always gathers in pipes, and a drip valve or drip pipe running down from that to take out the sediment. In that case they had forty pounds of steam pressure on that pipe that was forcing that oil on these burners. What does that man do? He unscrews that cap to let out that sediment (there was forty pounds pressure upon it), and the result was he had a two inch stream of oil, and anybody can tell what would be the result. That case was reported in the papers as an explosion of gas.

Just before I left home, I offered the risk to the agent of one of the biggest companies in the country, on my own station, which he declined, saying he would not write it at any price. "Well," he said, "to be candid with you, we don't know anything about it; therefore, we take the safe side and refuse." I took him through the station and explained the whole *modus operandi* to him, and I showed him the paper that I have read here. He said: "I want you to send a copy of that paper to our company, and we will investigate this matter, and if you will send it to the Insurance Exchange, and we will investigate it; and if the electric light folks wish to meet us, we will meet them at any time and have a committee appointed to study this whole matter." Now, there is the basis of what you want to do. My suggestion is that this association appoint a committee to meet a committee of the insurance companies to investigate this matter and put it upon the proper basis, and enlighten them upon this subject of electric plants.

Mr. Lockwood—I stated a few moments since that our insurance in Detroit was only increased 20 cents per $100, and what I now add is this: That when we put in our crude oil plant our insurance was very nearly expired. It did expire about three months since, and I have since renewed it, and renewed it at the same rate, and the result is that in the insurance, with the exception of paying at the rate of 20 cents more for $100, I have no trouble now in placing our insurance as well and as easily as I did before.

The Chairman—A motion has been handed up providing for the reconsideration of the motion to continue the committee on the New England Electric Exchange, passed this afternoon.

The motion was reconsidered.

Mr. Morrison offered a resolution, that a committee of five be appointed, with Mr. P. H. Alexander, chairman, to recommend a tax by some means that would secure to the National Electric Light Association the advantage now enjoyed by the New England Electric Exchange regarding the pleasant business relations between the electric interests and the insurance interests, and report at the next meeting of the association.

The motion was carried.

Mr. Alexander C. Chenoweth then read a paper on "Conduits; Their Material in Relation to Insulated Conductors." (See page 99.)

Mr. F. H. Whipple read a paper on "Municipal Lighting." (See page 100.)

Mr. A. R. Foote, of Cincinnati, read a paper on "Municipal Ownership of Commercial Monopolies." (See page 102.")

Dr. Moses, of New York, offered the following resolution, which was unanimously adopted:—

"*Resolved*, That the thanks of the National Electric Light Association be and are hereby tendered to the St. Louis Exposition and Music Hall Association, through David J. Harris, manager of the electrical exhibit, for the very cordial invitation of Feb. 19th for this association to hold its next convention in St. Louis, and the very generous offer of the use of Exposition Hall, and of free exposition space for convention purposes, and, be it further resolved that it is with regret that the association is obliged to decline the invitation above named."

Mr. Morrison moved the reconsideration of the action by which the resolution for the appointment of a committee on state and municipal legislation was referred to the executive committee, in order that the appointment be made by the chair.

The motion was seconded and unanimously agreed to.

The Chairman—The chair will appoint upon that committee, under the resolution of Mr. Morrison in regard to the New England Exchange, Mr. Alexander, chairman, and Messrs. Francisco, Cram, Woodbury and Perry.

Mr. Mason, Boston, offered the following resolutions, which were unanimously adopted:—

"*Resolved*, That the hearty thanks of the National Electric Light Association are hereby tendered to the Exposition society for the valued courtesies extended by it to the association during its present sessions.

"*Resolved*, That the National Electric Light Association desires to record its grateful appreciation of the valued and able services of B. E. Sunny, chairman of the executive committee, who, by the exercise of rare executive ability, has so largely contributed to the success of the meeting in Chicago."

Mr. Mason also offered the following resolution:—

"*Resolved*, That a committee of five, of which Mr. Arthur Steuart shall be chairman, be appointed, whose duties shall be to report at the next session of the association a plan for the incorporation of this body."

The motion was lost.

The Chairman—If there is no other business before us, the chair desires to return his thanks to you for the courtesy and consideration you have extended to him, and to say that he will give to his successor all the support he is capable of during his new administration. If there is no other business, I declare this convention adjourned, *sine die.*

EDISON'S INCANDESCENT LAMP PATENT ANNULLED IN CANADA.

A special despatch from Ottawa, of March 7, announces that Commissioner of Patents, Pope, of the Dominion of Canada, has rendered a decision annulling Edison's patent No. 10,654 of November 17, 1879, for incandescent electric lamps, on the grounds of importation and non-manufacture in Canada beyond the statutory limit of time. Under the statutes of Canada no appeal lies from this decision, which must be regarded as final. The proceedings arose originally upon a petition filed by the Royal Electric Co., of Canada, against the Edison Electric Light Co.

OUT OF ORDER?

A valued correspondent sends us the following note and enquiry :—

Much time and earnest discussion were devoted to the consideration of the report of the Committee on Underground Conduits and Conductors, at the recent Convention of the National Electric Light Association. The report of this committee seemed to be unsatisfactory to a majority of the members present. Why, then, was it "accepted?" After it *was* accepted, why was further action taken, which was contradictory to the action taken by the Convention in "accepting" the report?

Can it be that Mr. Morrison and other astute parliamentarians, were ignorant of the simple rule which is thus stated in Roberts' Rules of Order?

"When the assembly is to consider a report, a motion should be made to 'adopt,' 'accept,' or 'agree to' the report, all of which, when carried have the same effect, namely, to make the doings of the committee become the acts of the assembly, the same as if done by the assembly without the intervention of a committee."

THE EDISON FILAMENT PATENT SUSTAINED IN ENGLAND.

On the 18th of February, Lord Justices Cotton, Lindley, and Bowen, of the Court of Appeals delivered judgment, reversing the decision of Justice Kay, of the lower court, and sustaining the validity of the Edison English patent of November 10th, 1879. This is the second reversal of judgment in the course of the long litigation of the case, Justice Kay's decision last year being in reversal of an earlier one. An appeal still lies to the House of Lords.

REPEAL OF THE TELEPHONE RATE LAW IN INDIANA.

THE Indiana Legislature has repealed the act of four years ago, fixing a maximum charge for telephone service within the state. The question of rates is thus left to contract between the telephone companies and their subscribers. The business community of the state, it is understood, have been much dissatisfied with the situation during the past four years. The Central Union Telephone Co., whose business covered the greater part of the state, closed many of its exchanges soon after the passage of the law of four years ago, maintaining service on a toll system in the larger towns. The toll system was satisfactory neither to the public nor to the company. The Central Union company will now reorganize its Indiana business on its former basis. The experience of Indiana in limiting telephone charges by state legislation ought to give pause to the promoters of similar acts now pending in a number of states.

CORNELL UNIVERSITY.

ANNUAL INSPECTION TOUR OF ELECTRICAL AND MECHANICAL ENGINEERING STUDENTS.

The electrical and mechanical engineering students of Sibley College, Cornell University, will make the annual spring inspection tour during the coming vacation. They will start March 22d and return April 2d or 3d. The coming tour will be divided into four distinct trips; two west and two east. The western route taken by the electrical engineers will include Rochester, Lockport, Niagara Falls, Buffalo, Pittsburgh and Cleveland. At Rochester they will inspect the electric light stations and isolated plants, and at Lockport a visit will be made to the Cowles' Electric Smelting Co.'s works and the city light and power stations. They will then spend the Sunday at Niagara Falls and continue their journey on the 25th, taking in the Buffalo electric light stations and isolated plants. At Pittsburgh a visit will be made to the Westinghouse Electric Co.'s Works, the Standard Underground Cable Co.'s Works, the Faraday Carbon Co., and to other industrial establishments of interest to electrical engineers. The party will make a study of the electric railways of Pittsburgh and Alleghany, and at Cleveland will inspect the works of the Brush Electric Co. and National Carbon Co. The evenings will be spent at the various electric lighting stations. The eastern trip will include Albany, Troy, Schenectady, Yonkers, New York city, Brooklyn, Newark and Orange, N. J. The electrical engineers of the eastern trip will inspect the Edison Machine Works, Eickemeyer Works, Julien Station, Daft Works, Excelsior Works, various lighting stations of New York city, and the Metropolitan Telephone Exchange. A visit will be made to the laboratories of Mr. Edward Weston and Mr. Thomas A. Edison. On Thursday, March 28, they will visit the New York Electric Club. The western trip is under the charge of Professor Edward Nichols, and the eastern under that of Professor E. P. Roberts. The whole tour is under the management of Dr. R. H. Thurston, and it is largely through his efforts that these annual inspection tours are made so interesting and instructive.

PERSONAL MENTION.

MR. GEORGE A. HAMILTON is about to sever his connection with the Western Union Telegraph Co. to enter the New York factory of the Western Electric Co. Mr. Hamilton's ability and attainments as an electrician are too well known to be mentioned at this time. The officials of the Western Union Telegraph Co. are reluctant to lose his services. Mr. Hamilton is to be congratulated on his new connection, which affords a wider scope for talent and activity than the electrical and testing department of the Western Union service.

ELECTRIC STREET RAILWAYS IN AMERICA.

Now in Operation.

INVENTORS' RECORD.

Prepared expressly for The Electrical Engineer, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions,* 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From January 22, to February 12, 1889 (inclusive).

Alarms and Signals:—*Municipal Telegraph System*, T. J. Zoeller, 396,450. *Automatic Ground-Detector for Electric Circuits*, O. P. Loomis, 396,582. *Burglar Alarm*, A. C. Robbins, 396,667; G. B. Lehy, 396,701, January 22. *Electric Signaling Apparatus*, J. Young, 396,795, January 29. *Multiple Signal-Transmitter*, M. Martin, 397,194, February 5. *Automatic Alarm Apparatus*, E. Meyer, 397,657. *Electric Signaling and Alarm Apparatus*, W. L. Denio, 397,888, February 12.

Conductors, Indicators, Supports and Systems:—*Electric Wire Conduit*, J. Lynch, 396,407. *Underground System of Electric Wires*, H. B. Cobb, 396,543, January 22. *Insulating Pipe-Coupling*, S. Bergman, 397,218. *Junction-Box for Electrical Conductors*, W. M. Callender, 397,221. *Electric Wire Conduit*, W. B. Mack, 397,300, February 5.

Distribution:—*System of Electrical Distribution*, E. N. Dickerson, Jr., 396,-549. *Combination of Electric Generators*, E. W. Rice, Jr., 396,602. *System of Electrical Distribution*, E. W. Rice, Jr., and A. L. Rohrer, 396,603, January 22. *Electric Converter*, L. Gutmann, 397,461, February 5. *Regulating and Motive Device for Alternating Currents*, E. Thomson, 397,616, February 12.

Dynamos and Motors:—*Regulation of Alternate-Current Generators*, G. Pfannkuche, 396,422. *Dynamo for Telegraphic Purposes*, B. Gmur and O. Flatz, 396,557. *Coupling Dynamos*, O. P. Loomis, 396,580. *Coupling of Dynamos and Motors*, same, 396,581, January 22. *Device for Controlling Electric Motors*, H. H. Blades, 396,725. *Automatic Switch for Electric Motors*, G. H. Whittingham, 396,791. *Dynamo-Electric Machine*, P. Grant, 396,867. *Regulator for Dynamo-Electric Machines*, A. J. Holt, 396,932. *Armature-Winding for Dynamo-Electric Machines*, E. R. Knowles, 396,941. *Commutator for Dynamo-Electric Machines*, same, 396,942. *Regulator for Dynamo-Electric Machines*, J. F. Kester, 397,006. *Dynamo Electric Machine*, same, 397,007, Jan. 29. *Dynamo*, R. L. Cohen, 397,340. *Armature for Dynamo-Electric Machines*, O. B. Shallenberger, 397,392. *Dynamo-Electric Machine and Motor*, F. J. Patten, 397,439, Feb. 5. *Brush for Electric Generators*, R. Eickemeyer, 397,492. *Dynamo-Electric Machine*, R. M. Hunter, 397,550. *Regulation of Dynamos*, E. W. Rice, Jr., 397,613. *Electric Motor*, J. F. Denison, 397,702. *Method of Winding Field-Magnets*, T. A. Edison, 397,705. *Regulating Switch for Electric Motors*, H. H. Blades, 397,773. *System of Synchronizing Electric Motors*, F. J. Patten, 397,817, Feb. 12.

Galvanic Batteries:—*Electric Battery*, C. F. Heinrichs, 396,870, and 396,871, Jan. 29. *Galvanic Battery*, E. J. Colby, 397,111, C. E. Egan, 397,116, Feb. 5. *Method of Protecting the Negative Plates of Electrical Batteries*, F. J. Clamer, and J. G. Hendrickson, 397,489. *Galvanic Battery*, C. M. Thompson, 397,526. *Battery for Electric Belts*, W. G. Johnson, 397,806, Feb. 12.

Lamps and Appurtenances:—*Incandescent Lamp Socket*, O. P. Loomis, 396,583, Jan. 22. *Suspending Electric Light Lamps*, A. Siegrist, 396,897, Jan. 29. *Switch and Cut-Out for Electric Light and other Electrical Devices*, O. S. Bussmann, 397,109. *Incandescent Lamp Manufacture*, J. A. Vandegrift, 397,479, Feb. 5. *Automatic Switch for Electric-Arc Lamps*, E. R. Knowles, 397,729. *Electric Light Carbon*, H. S. Rheiner, 397,754, Feb. 12.

Measurement:—*Electric Meter*, M. J. R. Jacquemier, 396,403. *Electric Time Meter*, G. F. Card, 396,645, Jan. 22. *Revolving Photometer-Stand*, J. W. Packard, 396,951, Jan. 29. *Electric Meter*, H. H. Cutler, 397,538. *Telethermometer*, C. G. Hoffmann, 397,548, Feb. 12.

Medical and Surgical:—*Process of Making Dental Plates by Electro-Deposition*, J. G. Ward, 397,320. *Therapeutical Electrode*, L. T. Stanley, 397,474, Feb. 5. *Electro-Magnetic Attachment for Eye Glasses*, F. Fear, 397,790, Feb. 12.

Miscellaneous:—*Electrical Switch*, E. A. Sperry, 396,439. *Wiring Block for Electrical Circuits*, O. P. Loomis, 396,579. *Time Switch*, B. E. Waters, 396,632, January 22. *Electrically Operated Door Lock*, C. B. Beers, 396,723. *Electro-Magnetic Transmitter*, J. T. Williams, 396,792. *Tool for Splicing Wire*, H. G. Hubbell, 396,819. *Wire Hook*, P. Ashen, 396,847. *Electric Switch or Cut-Out*, E. R. Knowles, 396,880. *Electric Cut-Out Device*, J. C. Chamberlain, 396,920. *Automatic Electric Cut-Out*, E. R. Knowles, 396,940, January 29. *Hose Pipe*, E. H. Crosby, 397,171. *Electric Stop-Valve*, R. Wellens, 397,260. *Phonograph Recorder and Reproducer*, T. A. Edison, 397,280. *Electric Communicating System*, A. G. Holcombe, 397,364. *Protector for Electrical Instruments*, J. E. Crandall, 397,418. *Method of Demagnetizing Watches, etc.*, J. Greaves, 397, 423. *Connection of Electrical Circuits*, W. W. Griscom and H. N. Weidner, 397,424, February 5. *Electrical Stop-Motion Mechanism for Knitting Machines*, E. G. Conner, 397,537. *Electro-Magnetic Grain Scale*, W. A. Holley and U. Malin, 397,594. *Phonograph*, T. A. Edison, 397,706. *Safety Device for Electrical Circuits*, W. J. Hammer, 397,715. *Electric Switch*, A. E. Andrews, 397,826. *Method of Recording Speech*, G. H. Herrington, 397,956, February 12.

Railways and Appliances:—*Electric Railway Trolley and Support*, S. H. Short, 396,618. *Electric Railway System*, D. G. Weems, 396,633. *Turn Table for Cable or Electric Railways*, W. Davidson, 396,649, January 22. *Electrical Railway Signal*, W. P. Kookogey, 396,748. *Railway Signal*, same, 396,749 and 396,750. *Electric Lighting and Heating Cars*, J. F. Shawhan, 396,836, January 29. *Electric Railway Signal*, A. Z. Boda, 397,270. *Cable or Electric Street Railway*, W. S. Phelps, 397,385. *Overhead Contact and Switch*, C. J. Van Depoele, 397,451, February 5. *Electric Coupling for Railway Train Signaling*, W. C. Johnston, Jr., 397,558. *Apparatus for Heating Cars by Electricity*, R. M. Hunter, 397,857. *Overhead Line for Electric Railways*, F. J. Sprague, 397,875. *Electrical Railway-Gate*, M. Toulmin, 397,880, February 12.

Storage Batteries:—*Secondary Battery Charging*, C. F. Brush. 396,681, January 22. *Secondary Battery*, J. S. Sellon, 396,769, 396,770 and 396,958, January 29. *Method of Forming Secondary Battery Electrodes*, R. M. Hunter, 397,235. *Secondary Battery*, W. A. Shaw, 397,443, February 5. *Secondary Battery Plate*, E. R. Knowles, 397,557, *Process of Preparing Electrodes for Secondary Batteries* L. Paget, 397,607. *Electrode for Secondary Batteries*, same, 397,60°. *Secondary Battery*, W. Kingsland, 397,650. *Storage Battery Plate*, C. D. P. Gibson, 397,796, February 12.

Telegraphs:—*Sounder Attachment*, G. H. Carey and W. McArthur, 396,465, January 22. *Octuplex Telegraph*, M. W. Dewey, 396,734. *Railway Telegraph*, B. Cade, 396,983. *Railway Telegraphy*, same, 397,049, January 29. *Printing Telegraph*, A. T. McCoy, 397,466, February 5.

Telephones, Systems and Apparatus:—*Mechanical Telephone*, T. S. Davis and W. W. Davis, 396,688, January 22. *Telephone, or Analogous Electric System*, A. B. Ferdinand, 397,176. *Telephone Call Box*, A. Griffith and H. A. Burbank, 397,284. *Telephone Circuit and Apparatus*, J. A. Barrett, 397,331. *Telephone Paper Pad Holder*, J. B. Seymour, Jr., 397,472. February 5.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in March 1889.

Reported for the Electrical Engineer, *by* F. B. Brock, *Patent Attorney,* 639 *F street, Washington, D. C.*

Magneto Electric Battery for Firing Fuses, etc., B. G. Noble. 124,216 ; *Telegraph Insulator*, M. G. Farmer, 124,199, 124,200, 124,201, March 5, 1872 ; *Lighting and Extinguishing Gas by Electricity*, J. Vansant, 124,773 ; *Electro-Magnetic Engine*, W. Wickersham, 124,868 ; *Telegraphic Recording Instrument*, T. A. Edison, 124,800, March 19, 1872; *Electric Belt for the Body*, J. E. Bazault, 125,006 ; *Electro-Magnetic Apparatus*, 125,078, March 26, 1872.

[Drawings and specifications of any patent will be furnished by Mr. Brock at cost, 15 cents each.]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VIII. NEW YORK, APRIL, 1889. No. 88.

SECONDARY BATTERY LITIGATION.

THE decision of Judge Coxe in the case of the Electrical Accumulator Co. against the Julien Electric Co., elsewhere summarized, is important in its bearing upon the rights of the different concerns engaged in the manufacture of secondary batteries.

The contest as to who was the first inventor of the modern secondary battery, in which the active coating is applied mechanically to the electrode, began in the Patent Office in 1882. Chief among the claimants were Charles F. Brush, and Camille A. Faure. After a bitter struggle of four years, that tribunal declared Brush to be the first inventor, and patents were issued to him March 2, 1886, with broad claims for the invention.

The conflict was then transferred to the courts. The Brush Electric Co., the owner of the Brush patents, brought suit against the Electrical Accumulator Co., the owner of the Faure patent; the Electrical Accumulator Co. on its part, brought suit against the local Brush companies in New York; in Ohio against the Brush Electric Co. to repeal the Brush patents; and in the same suit the Brush Electric Co. filed an answer asking to have the Faure patent repealed. Besides this, both these companies sued the Julien Electric Co. for infringement of their respective patents.

The decision of Judge Coxe may apparently be regarded as practically settling all these controversies and clearing away this net-work of litigation. After an able and exhaustive discussion of the case, it is held that Brush was the first inventor of a secondary battery in which the active coating is mechanically applied to the electrode, but that Faure is entitled to a restricted claim for a battery in which the active coating is mechanically applied in the particular form of a paint, paste or cement. This claim of Faure's would seem, therefore, to be tributary to the broader claim of Brush, so that under this decision the Electrical Accumulator Co. may not be able to use even this particular form of battery without a license under the Brush patent.

In the case just decided, the Electrical Accumulator Co. sued upon four patents relating to secondary batteries—the Faure patent already referred to, two Swan patents, and a patent of Shaw & Rogers. The last named, however, was withdrawn and abandoned at the hearing. The two Swan patents are held by Judge Coxe to be invalid. The fourth claim of the Faure patent is also held to be invalid when construed broadly enough to be infringed by the defendants; while the first claim, the only remaining claim of the Faure patent sued upon, appears to be held to be invalid in its present form, for the reason that Brush is the first inventor of such a secondary battery. The Court states that if its owners will disclaim the broad invention, and will limit the claim of the Faure patent to a mechanically applied coating in the form of a paint, paste or cement, it will sustain this restricted claim and will grant that company an injunction and recovery under that claim.

The decision of Judge Coxe is of the more significance, because it is apparent that he has very carefully and thoroughly considered the most important of the vast mass of prior patents and publications and uses, relied upon by the Julien Electric Co. as anticipating the broad invention, and reaches the conclusion that the invention is not disclosed in any of them, and hence that Brush must be regarded as the first inventor of a secondary battery in which the active coating is mechanically applied to the electrode.

THE DOWNFALL OF THE COPPER RING.

THE month just closed has seen the collapse of the French monopoly of the world's supply of copper and the attendant ruin of the Comptoir d'Escompte, the great bank that tried to pull the Société des Métaux through its crisis. The rest of mankind may well feel some sympathy for the unlucky shareholders of the shipwrecked bank; but the members of the copper syndicate and all who took a hand in their gigantic "corner" will have to look only to the class of similar conspirators against the industries and commerce of the world for any commiseration in their losses. The American copper mine owners are said to be secured, in the main, for the copper they have furnished. It seems to be generally understood that, in addition to receiving a definite price from the syndicate, they were by agreement to get a portion of the profits of its operations. If that be true it would be gratifying to fair minded men to see them compelled to bear a corresponding part of such losses as may attend the liquidation of the syndicate's affairs.

The smash-up of the Société des Metaux leaves an accumulated supply of something over 100,000 tons of copper which must come upon the market. Apparently copper must fall below the normal price—the price regulated by demand and supply—and remain below it till the abnormal

stock be reduced to ordinary proportions. Meantime the production of the mines and smelting works will be reduced to hasten the arrival of a period of equilibrium.

THE bidding by the electric lighting companies on street lighting in New York, for the year beginning May 1, next, which took place March 27, illustrates a side of the subway question that has not been sufficiently regarded, at least by the public. Nearly every company tendering asked about twice as much per lamp on routes where they would be compelled to put their wires into subways as they did on pole-line routes.

Prominent members of so cautious and wary a body as the National Electric Light Association have on several occasions declared that the only obstacle to underground service is the cost; and when Mr. Carpenter Smith, at the recent Chicago meeting, held up to view a full pocket-book as a sample of insulation that would meet any strain whatsoever, he expressed the exact situation of the whole matter. Any desired insulation will be forthcoming if you will pay for it. So with conduits; a satisfactory subway is feasible if undertaken on broad enough plans and with sufficient money. In the present situation the electric lighting com panies find themselves compelled to incur large expense for underground conductors and to pay considerable sums for rental of conduits. The public should understand that if it insist on underground wires, it must pay at least part of the inevitable cost.

Two or three subway man-hole lids projected aloft by an explosion of gas and flying over people's heads in Madison Square, a few days ago, were a somewhat startling reminder that underground conduits may be quite as hazardous to the public as overhead wires, if not properly cared for. This sort of thing was predicted and has happened several times already in a number of cities. It will probably occur again, as will many other mishaps, electrical and other, serious or trivial, so long as the city having the largest electrical system in the world, confides so difficult and complicated a task as the devising, construction and regulation of its electrical conduits to men so conspicuously and absurdly incompetent as the machine politician, the theatre agent and the forward young attorney who constitute just three-fourths of the Board of Electrical Control. Neither its *ex-officio* member, the present energetic mayor, nor its capable electrical expert, Dr. Wheeler, can make such a board anything else than an object of alternate disgust and amusement.

ON the 29th of March, the Western Union Telegraph Co. attacked the Board of Electrical Control, through an order obtained from Judge Wallace, of the U. S. Circuit Court, temporarily enjoining the mayor and the board from directing the Commissioner of Public Works to remove poles and wires of that company from the streets. An order to show cause why the injunction should not be made permanent was made returnable in the Circuit Court April 3. The counsel of the Western Union company supported its application to the Court by alleging its right, acquired from the United States in 1867, to construct and maintain telegraph lines "over and along any of the military roads and post roads of the United States," under which designation the streets and avenues of this city are claimed to be included. It is further averred by the telegraph company that experience has shown that conductors placed in both their own and the public conduits are soon destroyed by heat and gas. Furthermore, it is charged in the complaint that the original Board of Electrical Control (Subway Commission) exceeded its duties by organizing a company to construct and maintain subways in the city streets, and in striving to compel the users of electrical conductors to rent spaces in those subways. The result of this proceeding will deeply interest the electric lighting companies, whose relations with the Board of Electrical Control are so accurately presented in the extract from *Texas Siftings* printed in another column.

ONCE more we repeat that the idea of street illumination by means of incandescent lamps is a fallacious and mistaken one.—*Electrical Review* (London).

Do not be too positive, neighbor. American experience, as we have been told more than enough times, is no criterion for England. Nevertheless it is a fact, that year by year, the use of the incandescent lamp for street illumination has gained in popular appreciation, and at least three of our leading companies, the Edison, the Thomson-Houston and the Westinghouse, are engaged in erecting street lighting plants with highly gratifying results. But note the fact that we always use 25 to 30 candle lamps, and not 10 or 16 candles; which makes all the difference in the world. The smaller candle-power does not give enough apparent illumination, and inferentially increases the cost of the plant by necessitating lamps at too short intervals. On the other hand, a higher candle-power than 30 implies greater intervals and a less satisfactory average distribution of light. One of the street plants of the Westinghouse company supplies 2,000 lamps, scattered through a district 12 miles long, from a single plant. The advantage of the incandescent system is more strikingly manifested on curved or heavily shaded streets. It looks to us, as if the idea of incandescent street illumination, instead of being a "mistaken one," is fast becoming recognized as a very sound and satisfactory one, except possibly for large open squares, and other exceptional places of like character.

IN contradicting the statement printed in the New York *World*, March 21, of the probable failure of the Villard scheme for consolidating the several Edison companies and bringing additional capital from Germany into the business, "a conspicuous friend of the Edison companies" is reported in the *Tribune* of March 22, to have said:—

There is no foundation for the printed statement, and certainly none for the conclusion that the negotiations have been broken off in consequence of the Canadian decision. * * * * There can be no monopoly of electric power; and for the benefit of the Westinghouse company, I will say that Mr. Edison has taken out no new patents lately, because he is treating the question of electric lighting as a mere business matter. The company that can furnish light at the lowest cost will be sure to get the business. The patent rights do not figure in the case at all. There is enough room in this country for more than two companies, and the greatest difficulty in both this country and Europe is to secure competent electricians. The expansion of the system is hampered by this lack.

For whose benefit soever made, this declaration is in refreshing contrast to many statements heretofore published

in behalf of the Edison company. It is a new sensation to be told that "the patent rights do not figure in the case at all." The statement is, we think, rather too sweeping, and hardly does justice to the position of the Edison company; although it is, perhaps, not so far wide of the mark as the immoderate claims formerly put forth.

We have received from the United Electrical Engineering Co., Limited, Westminster, England, an announcement of the undertaking by that company of the exploitation of the Jablochkoff patent of 1877 as covering electrical distribution by means of transformers. The communication states that the company has "concluded arrangements with the Leading Electric Lighting Companies involving both the recognition and support of the Patent." The following paragraph begins the announcement :—

It will not be a surprise to those who are familiar with the chronology of publications bearing on electrical distribution by means of transformers, and the terms of the judgment in favor of Messrs. Ferranti at the recent trial, that Jablochkoff's patent of 1877 is now recognized as covering the system.

It is not too much to say that it *will* be a surprise to a good many fairly familiar with the chronology of the subject if this movement result in the establishment of a monopoly in England of distribution by means of transformers.

Members of the electrical profession who depend upon the columns of our esteemed contemporary, the *Electrical Review*, for information and guidance upon points of patent law and practice ought to insist that its legal adviser be no longer permitted to formulate and indite his opinions at unseemly hours or after an evening at the Electric Club.

Immediately after the promulgation of the decision of the Supreme Court in the now celebrated Bate case, the following extraordinary tidings were spread abroad by him :—

An important patent decision extending the life of foreign patents to the extreme limit of time for which one can be granted, is published on another page.

Precisely how the life of a foreign patent is capable under any circumstances of being extended by a decision of the United States Supreme Court, we do not know. It has usually been supposed that foreign countries were out of its jurisdiction. In its next issue, after our contemporary's legal luminary had found time to study the opinion more carefully, it was announced that

The decision settled one point emphatically, and that is, that the life of an American patent first taken out in a foreign country, does not expire until *the extreme limit of time for which an extension of patent may be secured* in a foreign country.

The precise language in which the Supreme Court "settled" this point so "emphatically" is unfortunately not indicated, and so far as we are aware, nobody except our contemporary's solicitor has ever been able to find it; in fact the general impression among members of the bar has apparently been that the effect of the decision was about as nearly the reverse of the above statement as it well could be.

From a subsequent issue of the same journal we derive valuable information in respect to a decision on "one of the Edison lamp patents in Canada," and are informed that

This is, of course, not final, and like the decisions of our own Commissioner, is appealable.

It is hardly necessary to point out that the opinion thus declared by our contemporary overrules, reverses and inferentially pronounces unconstitutional the thirty-seventh section of the Canadian Patent Act, which provides that "if any dispute arises as to whether a patent has or has not become null and void under the provisions of this section, such dispute shall be decided by the Minister or the Deputy of the Minister of Agriculture, whose decision in the matter *shall be final.*"

Fortunately for the readers of our contemporary, its decisions in these matters cannot be regarded as "final."

Both parties to the storage battery suit just terminated appear to be well satisfied with the result. The Electrical Accumulator Co. announces that its Faure patent is sustained, whilst the Julien Electric Co. informs the public that it does not employ the process to which Judge Coxe limits the Faure claim, and does not desire to employ it.

OBSERVATIONS.

Judging from a recent article in the March number of *Electric Power*, that journal has become a convert to the "*motorneer*" idea.

Not that E. P. likes it, but because no other distinctive word is offered as a term for the man who starts and stops an electromotor. But is a distinctive term required? And is it necessary to have a word ending with the syllable "*neer*"? How about the man who starts and stops a water motor?

The observer likes this word less than many other really unnecessary words that have crept into use, for this reason among others, that it implies a species of monopoly in motor-ship to the electromotor; "Telegram," though perhaps not etymologically correct, is an expressive and not inelegant word, and there is good reason for its retention.

If this new word be adopted, it will be necessary to rob Peter to pay Paul; since, for euphony, the *n* from engineer has to be lugged in. Let others if they so desire become "*motorneers*"; the observer prefers, so far as this word is concerned, to remain a mutineer; *anglice*, a kicker.

. . .

Copper is coming down. Nay, it has come down. Since the downfall of our friends, Messrs. Secretan, *et al*, long prophesied, has come, we may expect shortly a reasonable decrease in the price of copper, and a proportionate increase in the amount used; especially in telegraphy and telephony.

The final crash of the syndicate was signified to the Boston copper mine stockholders, by the action of the Faneuil Hall Grasshopper, a huge insect of copper, having viscera composed of a large number of coins of several nations, which evacuated its perch on Monday, March 18th, while the citizens below, were celebrating the evacuation of Boston by the English. The grasshopper, however, is to be stitched up and promptly restored to its elevated post of observation, and in this instance, probably, will not serve as a portent, since it is heavy odds that the price of the rest of the world's supply of copper will be cheaper before it is dearer.

.. So rapid has been the development of the electric industry, few have been able to keep trace of its achievements, and fewer still have sounded its possibilities for the purpose of giving direction to its growth.—*A. R. Foote.*

.... As the freedom of the spirit is greater than the freedom of the body, so is the distribution of electric power freer than that of all other forms of force. It is their spirit.—*A. R. Foote.*

ARTICLES.

THE EFFICIENCY OF METHODS OF ARTIFICIAL ILLUMINATION.[1]

BY EDWARD L. NICHOLS.

(Professor of Physics in Cornell University.)

OF human industries of the present day none perhaps, save those which have to do with providing the race with food, clothing, shelter and fuel, is more important to the cause of material welfare than that which deals with the production of artificial light, and he who seeks a means of measuring the material civilization reached by a nation might find an excellent criterion in the progress which it exhibits in the art of illumination.

The problem of comparing the various methods of artificial lighting which are in vogue at the present day is one of great interest, whether we view it from the commercial standpoint, taking the cost of production as our controlling factor, or from the broader basis of relative usefulness, cost being relegated to a secondary position, or, finally, from the purely scientific point of view. From whichever side we approach this question, we are led inevitably to the consideration of certain elements which are alike of scientific, utilitarian and commercial importance.

At first sight the attempt to determine the relative value of two sources of light would seem to be a simple matter. The number of factors, however, which enter into such a determination is surprisingly large, and many of them are of a character which makes it difficult to give them definite and complete expression. Of these the greater part are indeed commonly left out of account altogether, for the sake of simplicity, and we content ourselves with an antiquated and totally insufficient measure of our sources of illumination, which we call candle-power. It is to these other elements which enter into the question of the character of artificial light—such, for instance, as have to do with its *quality*—but which are, as a rule, quite lost sight of, to which I would ask your attention this evening, together with a discussion of those which are commonly made use of in photometry. If, in so doing, I am led to speak of methods which belong to the realm of pure science, I trust that you will agree with me in thinking that the results are not unimportant even to those whose interest in the problem of the production of artificial light is purely utilitarian.

In the important question of the efficiency of a light-producing machine or process, the practice of to-day is very far from having reached that degree of exactness of expression which we demand in other cases of the transformation of energy. In electric lighting the energy expended is readily determined in absolute measure, or in that excellent practical unit, the *Watt*. In lieu of any attempt to express the useful energy obtained, however, we still content ourselves in practice with that most unscientific unit, the candle-power, based upon a source of illumination which is particularly subject to fluctuations of intensity and color. Even as used in the Bunsen photometer the shortcomings of the standard candle are sufficiently apparent; but no one who has not attempted to study it by methods which make it possible to detect changes of color as well as of brightness, can fully appreciate its fickleness.

Such as it is, we do not, moreover, make the best of the standard candle as a basis of comparison of artificial lights. We speak of a 16-candle incandescent lamp, for instance, meaning oftentimes "mean spherical candle-power" and then we compare it with a petroleum or gas flame, measured in the horizontal plane only, much to the disadvantage of the electric lamp. The study of the distribution of intensities in accordance with the very complete system devised for that purpose by the Franklin Institute Committee in 1884, affords an invaluable means of comparing the performance of various types of incandescent lamps; but the adoption of "mean spherical candle-power" as obtained by that method, is, to say the least, misleading when it comes to the comparison of electric lamps with candles, oil or gas. It is to be hoped that when the present confusion of methods of measuring candle-power now existing in the electric lighting establishments in this country is supplanted by a recognized system, the fairer standard already established by law in England, viz., mean horizontal candle-power, may be adopted. It is, however, in the comparison of arc and glow lamps that the latter are put at the greatest disadvantage. Here we pit the incandescent lamp, using mean spherical candle-power as our basis, against candle-power measured at the angle at which the arc light sends out the greater part of its rays. Indeed, in too many cases, it is not with the actual intensity even in this most favorable position with which we have to do, but with an estimated or "nominal" candle-power which the arc, in matter of fact, never approaches.

The electric arc stands quite alone, for the purposes to which it is adapted, and need fear no rivals. It does not need to be estimated upon any fictitious basis, and the continuance of the pernicious practice of ascribing to it powers of illumination which it does not possess must, in a great measure, be charged to the account of the standard candle; for with the best intentions in the world, the comparison of sources of light differing so widely in color as the candle and the electric arc, is nothing more than a rude approximation, leading by its very inaccuracy to the temptation of the grossest exaggeration.

There are, fortunately, better methods of estimating the efficiency of a lamp than that which is based upon candle-power.

We may, for instance, determine the ratio of the energy of the light-giving radiation to that of the total radiation of the source of illumination. The efficiency of the incandescent lamp, according to this definition, has been recently determined by Mr. Ernest Merritt,[2] of the Physical Laboratory of Cornell University. Mr. Merritt followed two independent methods of investigation. In his first experiments the lamp was placed in a calorimeter constructed entirely of glass, figure 1, through which a constant flow of

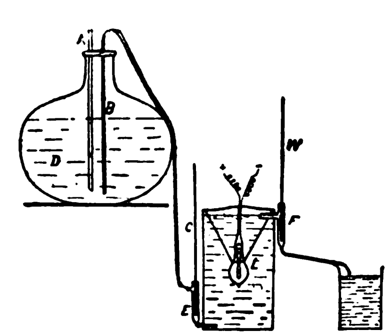

FIG. 1.

water was maintained. The temperature of the water upon entering and upon leaving the calorimeter was measured by means of the thermometers E and F. From this difference of temperature and the amount of water discharged in a given time, the heat absorbed by the calorimeter was calculated; proper corrections for loss of heat by radiations, etc., being applied. Now the water with which the calorimeter was filled is nearly transparent to the light-giving radiations from the lamp, and almost entirely opaque to the longer wave lengths which constitute the so-called heat spectrum. To have assumed it to be entirely so, would, however, have involved very considerable errors, and the diathermancy of the calorimeter on the one hand and its power of absorbing the luminous wave-lengths on the other, were accordingly carefully determined by methods

1. A paper read before the American Institute of Electrical Engineers, March 12, 1889.

2. Ernest Merritt, *American Journal of Science*, vol. 37, p. 167.

long since elaborated and made use of by Melloni and by his distinguished English follower, Professor Tyndall. By applying these and other necessary corrections, we are able to calculate very accurately in watts, the non-luminous radiation from the lamp. The ratio of the total radiation, obtained either by submerging the lamp in a metallic calorimeter or by direct computation from the current and electromotive force gives the actual efficiency of the lamp considered as a light-making machine. The result is not a gratifying one, when we compare this process with most others in which energy is transformed. The efficiency of the best types of incandescent lamps, previous to the introduction of the recent three watts per candle lamps now in successful operation, which would doubtless make a somewhat better showing, was found to be rather under than over five per cent. at normal candle-power; the values ranging from 0.5 per cent. to 6.5 per cent. The last-named value for the efficiency was attained only at a temperature incompatible with any considerable length of life. The results obtained in this investigation are shown in table i.[3] and in the accompanying diagram, figure 3.

TABLE I.[4]

Lamp A. Edison.

E. M. F.	W	C. P.	L	$\frac{L}{W}$	$\frac{L}{C.P.}$
74.2	34.6	0.9	0.18	0.005	0.59
91.6	56.2	4.8	0.68	.012	0.14
97.3	64.6	7.3	1.13	.017	0.15
100.3	69.3	8.9	1.62	.023	0.18
107.6	81.6	14.6	2.97	.036	0.20
109.3	84.4	16.3	4.57	.054	0.28
124.1	115.4	38.2	7.46	.065	0.19

In this table W is the total energy, in watts; L the energy of the light, also measured in watts; and C. P. the candle-power.

The second method pursued by Mr. Merritt was intended rather as a check upon the results already obtained than in the expectation of gaining further data. The rays of the lamp were allowed to fall upon the face of a delicate thermopile placed at a distance of about 60 cm. The thermopile was in circuit with a low resistance galvanometer of the well known "tripod pattern" of Sir William Thomson. The deflection of the galvanometer was taken as a measure of the total radiation, luminous and non-luminous, which fell upon the face of the pile. A cell containing a solution of alum was now interposed, and the reduction in the galvanometer noted. The arrangement of this apparatus is shown in figure 2.

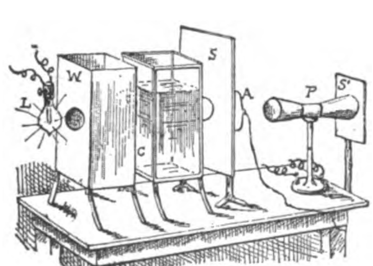

FIG. 2.

An aqueous solution of alum fulfills much more nearly the desired condition of complete opacity to "dark heat" and complete transparency to the rays of the visible spectrum than any other substance, but a certain small percentage of the longer wave lengths will pass through such a bath, and a considerably larger percentage of light-giving rays will be cut off by it. The proper corrections are, however, easily determinable, and when in this case they had been determined and applied, the ratio of total to luminous radiation was found to be in gratifying agreement with the efficiency obtained by the calorimetric method already described. See table ii.

TABLE II.

Lamp B.

An Edison 16 c. p. lamp. Resistance — 249 ohms.

E. M. F.	W.	C. P.	L.	$\frac{L}{W}$	$\frac{L}{C.P.}$

E. M. F.	W.	C. P.	L.	$\frac{L}{W}$	$\frac{L}{C.P.}$
72.0	21.6	0.4	0.46	0.021	1.27
87.4	33.5	1.5	1.10	.033	0.76
102.0	47.8	4.4	2.09	.044	0.48
117.0	66.1	10.7	3.19	.048	0.30

Lamp D.

Weston 16 c. p., 70 volt. Resistance — 152 ohms.

E. M. F.	W.	C. P.	L.	$\frac{L}{W}$	$\frac{L}{C.P.}$
43.0	25.8	0.5	0.53	0.021	1.06
50.7	36.0	1.6	0.97	.027	0.62
60.5	52.0	5.2	2.03	.039	0.39
67.5	65.5	11.0	3.95	.060	0.36

Lamp E.

Bernstein 8 c. p. Resistance = 11.3 ohms.

E. M. F.	W.	C. P.	L.	$\frac{L}{W}$	$\frac{L}{C.P.}$
12.2	25.2	0.2	0.20	0.008	1.00
13.4	30.8	0.5	0.41	.013	0.84
15.0	40.4	1.3	0.75	.018	0.57
16.4	53.2	4.1	2.03	.038	0.50

It is interesting to compare these results with some obtained by still another method. Captain Abney and Colonel Festing in the Proceedings of the Royal Society have described a series of elaborate studies of the radiation of the incandescent lamp. The portion of their very important investigation which has a bearing upon the efficiency, deals with the exploration of the spectrum of the lamp, under various degrees of incandescence, by means of an exceedingly sensitive thermopile. The energy of the visible spectrum of most sources of light is so minute that it has generally been deemed impracticable to measure it in this way. Captain Abney and his co-worker have, nevertheless, secured measurements covering not only the extensive regions of the so-called heat spectrum lying inside the red, but also the shorter wave lengths which constitute the

3. Dr. Blattner in an Inaugural Dissertation, published at the University of Zürich, gives similar values for the efficiency of the incandescent lamp. He finds, as the result of extended measurements with the glass calorimeter, that * * "at the normal temperature of incandescence, where the intensity lies in the neighborhood of 16 candles, the efficiency does not rise above five per cent. to six per cent."—Emil Blattner; *Der Optische Nutzeffect der Glühlampen*, Frauenfeld, 1886.

4. Tables i. and ii., and figures 1 and 2, are taken from Mr. Merritt's paper, already referred to.

visible spectrum. Their results are shown graphically in figure 3.

One of the British Electric Co.'s lamps was subjected to measurement in six different states of incandescence, corresponding to 33.6, 60.2, 93.8, 116.4, 130.8 and 150.5 watts respectively. The curves show the intensity of each wave length of the spectrum. When the above amounts of energy were expended in the filament, and the total area inclosed by each curve affords a relative measure of the total radiation of the lamps in the state of incandescence in

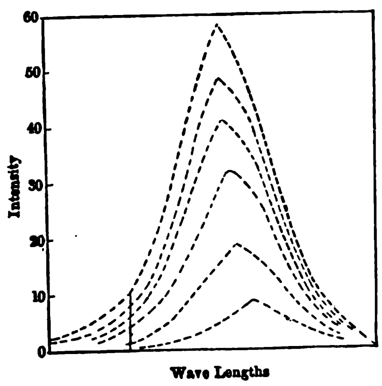

FIG. 3.

question. I have added to this diagram, of which, in other respects, figure 3 is a faithful reproduction, the vertical line lying between scale divisions 5 and 6 of their scale. This line marks the boundary between the visible and invisible spectrum. The entire area to the right of that line represents the energy wasted in the lamp; the much smaller area to the left comprises the light-giving rays. The ratio of the entire area of each curve to that portion lying within the boundaries of the visible spectrum gives us the efficiency of the lamp for the state of incandescence produced by the expenditure of the number of watts for which the curve is drawn. This ratio increases from a very small value with the brightness of the lamp.

I have made approximate integrations of the areas embraced by the curves for 150.5 and 130.8 watts, respectively, for the purpose of comparing the efficiency thus calculated with the results obtained by Mr. Merritt. The ratios are :—

Watts.	Efficiency.
150.5	5.55 per cent.
130.8	5.15 "

The corresponding values for lower states of incandescence are all smaller than the above.

It will be seen that these results are in complete agreement with those obtained with the glass calorimeter and by the method of Melloni. We have, indeed, reason to feel that our knowledge of the absolute efficiency of the incandescent lamp, in so far as it can be expressed by the ratio of luminous to total radiation is well grounded, and that we are in position to determine the light-giving efficiency of any type of glow lamp in any condition of incandescence with the same certainty and exactness which is attainable in the measurement of other machines for the transformation of energy.

The average net efficiency of the incandescent lamps of to-day, for we may leave untouched for the present the efficiency of the processes by which the latent energy of fuel from which the current is generated has been converted into electrical energy, is rather below, than above five per cent.; and since the ratio of total radiation to light-giving radiation increases but slowly as the temperature of the radiating body rises, the efficiency is not likely to be increased in any very marked degree until we shall have learned how to suppress altogether these long wave lengths which yield us dark heat, and are able to limit the vibrations of our source of light to that brief octave which comprises the wave lengths to which alone the human retina responds.

Whether this great step is to be made by robbing the glow-worm and fire-fly of their secret, as has been suggested in a recent address by the director of the Sibley College of Mechanical Engineering,[5] or by development along the lines sketched the other evening by Professor Brackett at the meeting of the Electric Club, or by the application of some principle as yet unconceived, we know not. Meantime, we have in the methods of artificial lighting of to-day abundant material for study and investigation.

The investigation of the efficiency of the arc light by the methods under consideration, is a much more difficult matter than the same determination in the case of the incandescent lamp. The radiating surface of the latter is very nearly of the same temperature throughout, and the ratio of total radiation to luminous radiation, obtained for the bundle of rays sent out in a single direction, gives us at once the measure of the efficiency. In the arc we have, however, a light-giving area of great brilliancy in the immediate neighborhood of the arc, and the temperature of the carbons falls with great rapidity from the maximum at the point and crater to regions which are at a red heat.

The entire light-giving area is included between the line surrounding the positive carbon, which is at red heat, and the corresponding line upon the negative carbon. Between these two lines we pass rapidly through regions, the light from which varies with the degree of incandescence by insensible gradations from that which a red hot surface is capable of emitting to that coming from carbon at the highest temperature which that substance can be made to assume. Now, the curve of distribution of candle-power taken in a vertical plane is, as we all know, a very peculiar one, and if we place our thermopile with alum cell interposed to measure the energy of the light-giving rays, the amount of radiation received upon the face of the pile will greatly depend upon the position in which the apparatus is set up. At an angle of 45 degrees, or 50 degrees below the horizontal plane, for instance, the amount indicated will be five or six times greater than in the horizontal plane. Now, the surface of total radiation is much larger than that from which the light-giving rays emanate. It includes, in addition to the incandescent surfaces near the arc, all those portions of the carbons which are heated, either by conduction or by the current.

The amount of heat radiated from regions which are below the red heat is very considerable, and forms an important factor in the determination of the efficiency. Were the distribution of total radiation in the vertical plane identical with that of the light-giving rays, the measurement of their ratio with the axis of the thermopile in any plane which passes through the arc, would give us the efficiency of the lamp; but the curve of distribution of total radiation is not the same as that of candle-power, and the ratio in question is a function of the plane which the axis of the pile makes with the horizon. It becomes necessary, therefore, to make an exploration of the entire zone through which the lamp sends out rays, determining the ratio of total to luminous radiation for each angle, and then to integrate the results. Such an investigation is now in progress under my direction, and Mr. H. Nakano, who is carrying on the experiments, has reached some exceedingly interesting results. The research will soon be ready for publication in its complete form, and it will

5. "The second of these greatest of inventors is he who will teach us the source of the beautiful soft-beaming light of the fire-fly and the glow-worm, and will show us how to produce this singular illuminant, and to apply it with success practically and commercially. This wonderful light, free from heat and from consequent loss of energy, is nature's substitute for the crude and extravagantly wasteful lights of which we have, through so many years, been foolishly boasting. The dynamo-electrical engineer has nearly solved this problem. Let us hope that it may be soon fully solved, and by one of those among our own colleagues who are now so earnestly working in this field, and that we may all live to see him steal the glow-worm's light, and to see the approaching days of Vril predicted so long ago by Lord Lytton."—ROBERT H. THURSTON—*Transactions of the American Society of Mechanical Engineers*, 1881, p. 22.

afford us much more definite data concerning the radiations of the electric arc than we now possess. It will not be out of place even now to say a word concerning the method which is being employed, and the general character of the results already obtained.

The first measurements were made by the second method employed by Mr. Merritt, the thermopile in the horizontal plane. The lamp subjected to measurement was of the long-arc type, with 9 amperes of current and 45 volts. The efficiency in this plane was found to be surprisingly small. It was found, moreover, to vary in marked degree with the diameter of the carbons used, increasing as the diameter decreased to the point at which the carbons were rendered hot by the current, when, as might be expected, it fell off again.

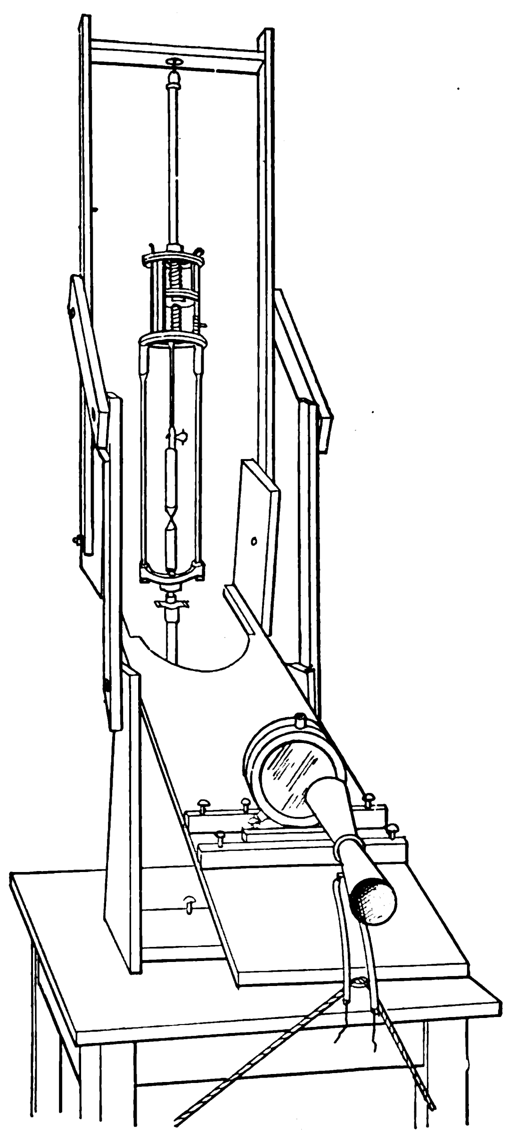

FIG. 4.

The lamp was then mounted in a frame which also carried the thermopile and alum bath, and which was so constructed that measurements could be made at any desired angle. All necessary changes of angle could be made without varying the distance from the arc to the face of the pile, or the relation of the alum bath to the latter. By means of this apparatus, which is shown in figure 4, it has been found possible to determine the ratio of total to luminous radiation throughout the zone of radiation of the lamp, and to plot the curve of distribution of each.

Without entering into the details of an incompleted research, I may indicate the general character of the results by means of a diagram. The curves shown in figures 5 and 6 are those relating to a "long-arc" lamp with carbons .45 inch in diameter. They represent respectively the distribution of luminous and total radiation emanating from the lamp. The radii show the positions for which

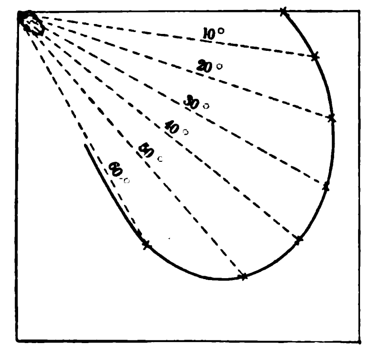

FIG. 5.

measurements were taken; distances measured along these lines from the origin to each curve give the relative intensities of light-giving and total heat energy in each position.

The curve of luminous radiation corresponds in form with that of candle-power. The distribution of total

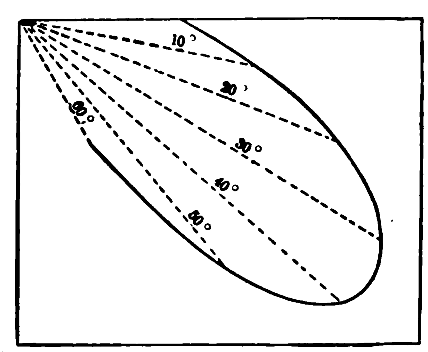

FIG. 6.

radiation, however, differs widely from these, and the ratio, $\frac{\text{luminous energy}}{\text{total energy}}$, is a function of the angle which the line of measurement makes with the horizontal plane. The values of the efficiency in the case in question for the various angles at which measurements were made, are given in table iii. They form the basis for the curve in figure 6, which is the diagram of efficiencies of the arc light under the conditions of operation already stated.

TABLE III.

Efficiency of an arc lamp; after measurements by Mr. H. Nakano.

Angle.	Efficiency. $= \frac{\text{Luminous radiation.}}{\text{Total radiation.}}$
0°	.0548
10°	.0901
20°	.1228
30°	.1506
40°	.1552
50°	.1059
60°	.0676
63°	.0492

The integration of these values gives as the mean efficiency of the arc lamp in question, .104, or 10.4 per cent.

The ratio of the radii of two semicircles, the areas of which equal the areas inclosed by the curves of luminous and total radiation, gives us a measure of the "mean spherical" efficiency of the lamp. This ratio in the case of the lamp to which these curves refer is very much smaller than the generally accepted values of the efficiency

of arc lamps, expressed in terms of the candle-power per watt, would lead us to expect. The intensity of the arc is, however, seldom expressed in mean spherical candles, and there are few data relating to the candle-power of this source of light upon which to found satisfactory estimates. On the one hand we find it stated, doubtless correctly, that the mean light-producing efficiency of the eleven dynamos, tested at the International Health Exhibition, held in London in 1884, was 1,440 candles per horse-power,[6] while the glow lamps only yielded 175 candles, and it is with estimates similar to the above with which we have generally to satisfy ourselves in comparing arc and incandescent systems of illumination.

For the purpose of deciding whether the results of Nakano's method of determining the ratio of luminous to total radiation are compatible with our other sources of knowledge concerning the arc light we must make use of mean spherical candle-power as our basis of comparison.

Very careful measurements of the mean spherical candle-power of two arc lamps of representative and successful commercial types were made in the physical laboratory of Cornell University,[7] following the method of the Franklin Institute Committee. Both of these lamps were rated at 2,000 c. p. They were maintained by dynamos of the types for which they had been especially designed, working under normal conditions. One of the lamps gave a mean spherical candle-power of 295, when working in series with nine other lamps of the same construction. When placed in circuit alone, the candle-power rose to 348. The energy expended in the lamp in each case was 550 watts, and the efficiency accordingly 1.8 watts and 1.6 watts per candle.

The other lamp was found to reach 609 mean spherical candles at the cost of 601 watts. An inspection of the result obtained by the Franklin Institute Committee would lead us to regard these as extreme values, between which the performance of almost all arc light would lie, as a rule, nearer the lower than the upper of these limits. The efficiency of arc lights, then, expressed in mean spherical candle-power per watt is frequently as low as 1.5 times that of the incandescent lamp, and, rarely, three times as high. Now the mean efficiency of the arc lamp under discussion *i.e.*, the ratio, $\frac{\text{luminous radiation}}{\text{total radiation}}$, according to the measurements of Mr. Nakano, is almost exactly 10 per cent. The efficiency of incandescent lamps, defined in the same way, according to Mr. Merritt, may, as we have seen, be taken at about 5 per cent. The ratio is 2:1 in favor of the arc lamp, which lies within the limits determined by comparison of candle-power and watts.

Small as these values for the efficiency of the electric light are, they show marked improvement over the efficiency determined in a similar manner for sources of illumination which depend upon the incandescence of carbon by direct combustion. More than a quarter of a century ago, Julius Thomsen[8] presented before a gathering of Swedish men of science, the results of an investigation of the energy consumed in the sperm candle, and in various oil and gas flames. His memoir bore the suggestive title of the Mechanical Equivalent of Light, and is one of the earliest contributions to our knowledge of the energy of luminous radiation.

The instruments employed in Thomsen's experiments were the thermopile and galvanometer, the indications of which were reduced to absolute measure by determination of the deflection produced by the radiation from a glass globe filled with hot water. The total loss of heat by radiation which this globe suffered was calculated from its rate of cooling, using Dulong and Petit's law. The water equivalent of the globe was 1,351 grains; its total loss of heat per minute at 50 degrees C. was 250 calories; its loss of heat by radiation at the above temperature, when the air of the room was at 17 degrees, was 102 calories per minute. Under these conditions the influence of the globe of water upon the thermopile placed at a given distance was observed. A luminous body having been substituted for the globe, its influence on the pile was likewise noted, and its total radiation in calories calculated by comparison of the deflections produced in the two cases.

For a sperm candle burning 8.2 grains per hour, the total radiation estimated by this method was 210 calories per minute. Other flames gave out quantities of heat nearly in proportion to their candle-power, as will be seen by inspection of table iv.

TABLE IV.

Calories per candle-power radiated by various flames, according to Julius Thomsen.

Source of illumination.	Candle-power.	Calories per candle.
Sperm candle..........	1.	210
Gas flame.............	1.2	201
Gas flame.............	7.7	199
Moderator lamp........	8.6	199

The luminous energy was obtained by a method similar to that pursued by Merritt in the experiments already described. A bath containing a layer of water 20 cm. in thickness was interposed between the lamp and the thermopile and the indications of the galvanometer noted. The results were based upon the assumption that the cell absorbed 13 per cent. of the light and all of the dark rays. This estimate is doubtless faulty, and may involve a reduction of several per cent. from the values given by Thomsen. His results, uncorrected, are as follows :—

TABLE V.

Energy of luminous radiation of various flames in calories, according to Julius Thomsen.

Source.	Candle-power.	Luminous energy per c. p.
Candles..................	1.	4.4 calories.
Moderator lamp...........	6.25	3.9 calories.
Moderator lamp...........	8.6	4.1 calories.
Gas......................	7.7	4.2 calories.
Gas......................	1.2	3.7 calories.

The energy of the light-giving rays per candle-power of light produced is then, according to Thomsen, very nearly the same for the flames of the candle, oil lamp and gas burner. This conclusion has been abundantly confirmed by spectrophotometric observations of the quality of the light which they emit. It appears, moreover, from these observations, of which I shall have occasion to speak at length presently, that the temperature of the incandescent particles in such flames agrees very closely indeed with that of an incandescent lamp, consuming 5 watts at 16 c. p, being, as a rule, lower, rather than higher, than the latter; and the calculation of the energy of such a lamp in calories per minute, making use of the data furnished us by the investigation of Abney and Festing, or of Merritt, affords most satisfactory evidence of the accuracy of Thomsen's results. Let us take for example the case of an incandescent lamp in which 5 watts per candle-power are expended, and in which the ratio

$$\frac{\text{Luminous radiation}}{\text{Total radiation}} = .05.$$

The energy converted into light in such a lamp is .25 watt. Now,

$$1 \text{ gramme-calorie} = 4.2 \times 10^7 \text{ ergs.}$$

$$1 \text{ watt} = 10^7 \text{ ergs} = \frac{1}{4.2} \text{ gramme-calories per second.}$$

$$.25 \text{ watt} = \frac{.25 \times 60}{4.2} \text{ gramme-calories per minute,}$$

and the heat equivalent of the luminous energy is 3.6 gramme-calories per minute.

8. Julius Thomsen: Das Mechanische Æquivalent des Lichtes; *Poggendorff's Annalen, Bd.* 125, p. 348.

This value is somewhat smaller than those given by Thomsen in the preceding table, but proper corrections for the diathermancy of the water bath used in his experiments and for the difference in standards of candle-power —the light given by his sperm candle being slightly in excess of the legal standard of the present day—will bring the two into excellent agreement.

The entire energy developed by the chemical reactions occurring in these flames per candle-power of light produced were, however, about 1,400 calories in the case of candle and oil lamps, and 4,100 calories in the case of gas, so that the gross efficiency would be respectively 0.3 per cent., and 0.1 per cent. The average ratio of total radiation reaching the thermopile to luminous radiation is about .2 per cent., but this ratio cannot be considered in the same light as that obtained in the case of the incandescent lamp, since a gas or oil flame is in reality a column of heated vapor containing particles of unconsumed carbon, which reaches far above the luminous region, sending out dark rays from its upper and cooler portions, which do not reach the face of the thermopile at all. The relation which the total radiation of this heated column bears to the heat dissipated by convection cannot be determined, and the determination of total radiation from the light-giving portions alone is of little value. It is only in the matter of gross efficiency, therefore, that we can institute a comparison between electric lamps and the older methods of illumination, and the gross efficiency of the former depends upon the efficiency of production of electric current. Under conditions, such that 10 per cent. of the total energy of the fuel consumed is converted into electricity—conditions, which are, I believe, rarely attained by our present methods—the gross efficiency of an incandescent lamp, of which the net efficiency, determined by the methods which I have already described, is 5 per cent., would be 0.5 per cent ; a value which is five times greater than that of a lamp burning the kind of gas used by Thomsen, and which stands in the ratio of 5 : 3 (or, probably, rather more than that) to the gross efficiency of an oil flame. These flames must, of necessity, vary very widely with the quality of the fuel consumed, and with the condition under which combustion is maintained.

If we apply a similar method of computation to the values given by Mr. Preece in his recent address at the Bath meeting of the British Association for the Advancement of Science,[9] assuming that the conditions under which each illuminant is consumed are such that the temperature of the incandescent carbon equals that which is maintained in the filament of an incandescent lamp at 5 watts per candle, with a net efficiency, as before, of 5 per cent., a set of conditions which can be attained in practice only in the most perfectly constructed oil and gas lamps, and which are fulfilled in many of the best of our incandescent lamps of to-day, we obtain the following results :—

TABLE VI.

Gross efficiency of various illuminants deduced from the values given by Preece. The heat equivalent of a candle is assumed to be 3.6 gramme calories per minute.

Illuminant.	Watts per candle. (Preece.)	Gramme-calories per minute per candle.	Luminous radiation. / Total radiation = gross efficiency.

Cannel gas.....	48	685.	.00521

9. Preece. Address before Section A, meeting of the B. A. at Bath, 1888. Nature, vol. 38, p. 496.

In considering these values it should be borne in mind that coal-gas is a fuel which has been obtained by the previous expenditure of considerable energy. Were we to take as our basis the consumption of coal necessary to the production of a candle-power of light, instead of the heat of the combustion within the gas flame itself, the values for the efficiency of coal-gas as an illuminant would be very considerably reduced.

We have already seen that there are excellent experimental grounds for the statement that the gross efficiency of the incandescent lamp is about .005, and that of the arc lamp about .01, under the assumption of the waste of 90 per cent. of the total energy of the fuel in the various processes leading to the production of the current, and that the latter figures, small as they are, are considerably in excess of the gross efficiency of candles, oil or gas. We are in possession, moreover, of the means of expressing exactly the degree of superiority which the electric light possesses over those illuminants in the important matter of the heating effect upon the surrounding atmosphere. Gas and oil flames deliver in the neighborhood of 1,000 gramme-calories of heat per minute to the room for each candle-power, of 3.6 gramme-calories of luminous radiation. An incandescent lamp of 5 per cent. net efficiency delivers only 72 gramme-calories per candle-power.

The net efficiency of the incandescent lamp may be raised somewhat by increasing the temperature of the carbon filament, and, indeed, it has already been somewhat raised by the introduction of the new "3 watt" lamps. These lamps have been excluded from this discussion because we have as yet no complete data with reference to them, and because it seemed desirable, aside from that, to institute comparisons between sources of illumination in which the degree of incandescence was the same, and for all of which, consequently, candle-power had the same meaning.

When we raise the temperature of our source of light, however, we introduce changes, of which the methods thus far considered take no cognizance.

In increasing the degree of incandescence, the ratio of luminous energy to total energy of radiation is slowly increased, and at the same time the relative brightness of the various rays which constitute the visible spectrum changes. In a word, the *quality* of the light changes, and we are confronted by important variations which cannot be expressed in candle-power.

The investigation of these changes in composition, upon which color depends, involves the study of the visible spectrum of the source of light and the comparison of its intensity, wave length for wave length, with the spectrum of some properly chosen standard. The instrument necessary to this work is the spectro-photometer, by means of which the spectra of the two lights to be compared are brought together in the field of view, one above another, like wave lengths everywhere in the same vertical line. The measurements consist in bringing the two spectra to the same intensity in each of the regions selected for observation successively, and in determining the amount by which it is necessary in each case to reduce the intensity of the brighter. A variety of devices have been made use of for varying the brightness of the spectra, and the standards of comparison adopted by different observers have included the candle, the petroleum flame, the gas flame, and the incandescent lamp, maintained at a constant voltage. Thus W. H. Pickering[10] obtained the necessary range of intensities by placing the lamp under inspection upon a sliding carriage and varying its distance from the slit of the spectroscope. His standard of comparison was a gas flame. H. C. Vogel[11] used as his standard a petroleum flame. Crova,[12] who brought the intensities of the two spec-

tra to equality by means of a polarizing device, adopted the moderator lamp as a standard. Otto Schumann, in his study of the incandescent lamp, made use of a "benzine" candle. The intervention of a revolving disc with open and closed sectors and of wedges of smoked glass have also been applied to the regulation of the intensity, and the method of varying the width of the slit itself, a device due to Vierordt, has been found to give good results, where the range of intensities was inconsiderable.

The methods of presenting the results of this class of measurement have differed as widely as the methods of observation and the choice of standards; but it is possible wherever the data are properly given and the character of the standard is known, to reduce them all to a common basis of comparison. When thus reduced these measurements are found to agree in all essential particulars, and they afford us very definite knowledge of the character of the light emitted by the sources of illumination to which the spectro-photometer has been applied.

Figure 7 shows the form of the spectro-photometer recently used by Mr. W. S. Franklin and myself in an extended series of observations upon artificial sources of illumination and in the comparison of their spectra with that of daylight.

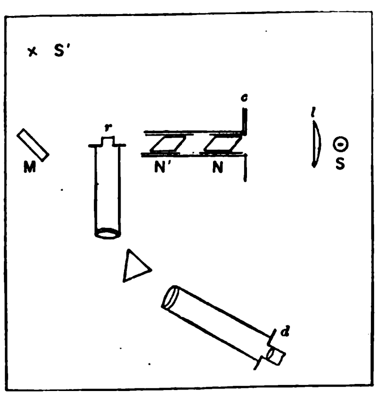

FIG. 7.

To the slit of a one prism spectroscope are attached a set of total reflection prisms, *r*, by means of which rays may be introduced into the upper and lower halves of the slit, these rays coming respectively from sources of illumination placed to the right and left-hand in a line at right angles to the axis of the collimator tube. The standard of illumination, which is an incandescent lamp S, maintained at 16 candles, is placed at the observer's right hand.

Its rays having been rendered parallel by means of a condensing lense, *l*, pass through a pair of Nicol's prisms, N and N', the first of which is free to revolve, and enters the upper half of the slit. The intensity of the spectrum of this lamp can be reduced at will by the rotation of the first Nicol, and its brightness is calculated from the angle between the flames of polarization of the two Nicols. To the left of the slit is mounted a block of magnesium carbonate, its face vertical and forming an angle of 45 degrees with the axis of collimation of the spectroscope. The rays of the source of light to be investigated, S', which is placed at a convenient distance, fall upon the magnesium carbonate, and it is such of the diffusely reflected rays from the latter as reach the total reflection prisms, and thus enter the lower half of the slit, which form the second spectrum. The object gained by the interposition of this white surface is an important one. All artificial light, except that from an incandescent lamp, emanate from glowing materials varying greatly in temperature, and the spectrum obtained directly from the source is always that due to some particular portion of the luminous body under investigation, to the exclusion of the remainder, and differs more or less in character from that of the source taken as a whole.

The spectrum of rays reflected from the face of the magnesium carbonate, however, contains in proper proportions the light from all portions of the source, and one of the chief sources of error to which spectrophotometric work is subject, is thus eliminated.

The investigations made with this instrument, which have been described in a paper read before the American Association,[13] included the measurement of candle flames, and of various petroleum and gas lamps, also of the lime light, the incandescent lamp under a wide range of conditions, of the electric arc and of daylight by clear and by clouded sky. The results obtained illustrate the precise character of those differences in composition to the bearing of which, upon the study of the efficiency of artificial illumination, I desire to call your attention.

In the first place it was found that the light of the candle, and of oil and gas flames, although subject to considerable fluctuations from variations of the condition under which combustion occurs, differ but slightly in quality from each other and from that of incandescent lamps maintained at normal candle-power. The incandescent material in all is carbon; and it is a significant fact that the average temperature of incandescence is nearly the same in all luminous flames, and that the highest temperature, until very recently at any rate, at which it has been found practicable to maintain the carbon filament of the glow-lamp, is very nearly that at which the same material exists under the most favorable conditions in oil and gas flames. Hence it is that the radiant energy per candle-power, as has been shown by Julius Thomsen, is nearly the same for all these flames.

Passing to other sources of illumination, such as the lime light and the electric arc, we find the entire portion of the spectrum lying beyond the yellow increasing more rapidly, regions of longer wave length than the yellow increasing less rapidly than the candle-power; the rate of increase

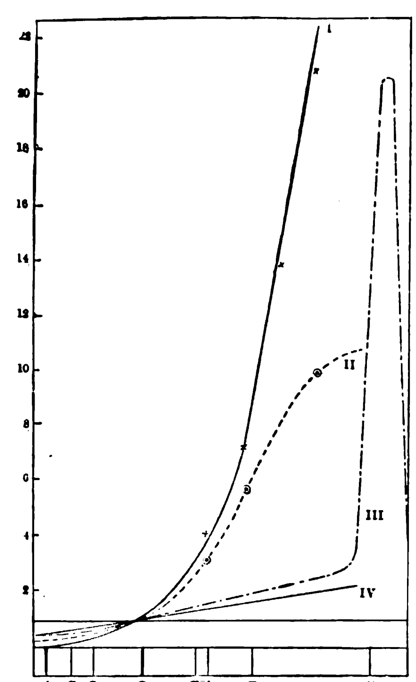

FIG. 8.

growing steadily as the wave length diminishes from the red to the violet end of the spectrum. Figure 8 shows the results of comparisons of the spectra of the lime light, electric arc, and of daylight, by clear and by unclouded sky, with that of an incandescent lamp maintained at its normal candle-power. This lamp, which was chosen as a

13. Edward L. Nichols and W. S. Franklin. A Spectrophotometric Comparison of Artificial Sources of Illumination. Paper read before Section B.; A. A. A. S. at the Cleveland meeting, August, 1888.

standard of comparison, was an Edison 16-candle, 100 volt lamp. Its light was precisely similar to that of a "Board of Trade" argand gas burner, showing the same relative brilliancy throughout the whole of the visible spectrum. The measurements were made with the spectrophotometer just described (see figure 7), the light in every case falling upon the block of magnesium carbonate, and entering the slit of the spectroscope after reflection from the face of the latter. For purpose of comparison the brightness of the standard incandescent lamp has been taken as unity throughout the spectrum. If we make a diagram in which abscissæ are wave-lengths and ordinates, intensities, referred to that of the standard as unity, the curve for this lamp will be a straight horizontal line, with ordinate = 1.

All other spectra are reduced to the same brightness in the region of the D line of Fraunhofer, and their brightness in other regions, referred to that of the corresponding wave length in the spectrum of the standard, is shown by means of curves.

Observations were made in ten regions of the spectrum, equi-distant as to wave length, and embracing the whole of the visible spectrum. It will be seen by reference to the figure that the lime light is relatively much stronger in the violet and much weaker in the red than the standard. In the arc light this increase of intensity toward the violet is even more marked, but its variation in quality from the lime light is by no means so great, as its exceedingly brilliant, bluish-white appearance to the eye would lead us to expect. The source of that appearance and of the very high actinic value of the arc is found, however, in the presence of an exceedingly bright band in the extreme violet. Here the relative intensity of the arc light spectrum rises abruptly about 3 to 20 times that of the incandescent lamp.

Measurements were made upon a long arc lamp with ½-inch carbons, with 10 amperes and 50 volts and a short arc lamp with a 20 ampere current. The character of the light was found to be almost identical excepting in this light band in the neighborhood of the G line, which is much more prominent in the long arc lamp. The character of the light was found to be much the same at all angles below the horizontal plane.

The only other spectrophotometric measurements of the electric arc with which I am acquainted, have been made upon the Foucault regulator, a lamp with carbons of small diameter. Fairly concordant determinations of the distribution of intensities in the spectrum of this lamp by W. H. Pickering,[14] H. C. Vogel,[15] and Crova,[16] show that the light of this lamp is decidedly bluer than that of the lamps with large carbons in vogue at the present day; the spectrum of the former being about five times as rich in the violet as that of gas or oil flames. Mr. Nakano's results, of which mention has already been made, indicate marked increase in the efficiency of the arc lamp, as the diameter of the carbons is decreased; and since increase of efficiency arises from a higher average degree of incandescence, we should expect just such an increment in the shorter wave lengths as shows itself in the case of the Foucault regulator.

Finally, in the case of daylight we find the intensity of the shorter wave lengths exceedingly great as compared with that of any artificial source of illumination. If the spectrum of daylight be brought into comparison with that of an incandescent lamp, and the two be reduced to the same intensity in the yellow, the extreme red of the daylight spectrum will be so *dim* in comparison with that of the lamp as to render measurements difficult. In the violet the discrepancy will be just as marked, the sun's spectrum being relatively of enormous brilliancy. Curve i., figure 8, shows the result of such a measurement of the daylight spectrum, taken just after noon upon a cloudless summer day.

Vogel has given data of a determination in which the preponderance in the violet was even more marked, the relative intensity of daylight for the region corresponding to wave length, 4,260 (just beyond the G line), being 100 : 1 for spectra which were equally bright in the neighborhood of the D line.

Ordinarily, there is considerable absorption of the blue and violet by moisture in the atmosphere, and a measurement of daylight under a densely clouded sky gave curve ii. Even under these conditions, with the violet reduced to about one-tenth of the value which it possesses in clear weather, daylight is very much bluer than any artificial light. The light emitted by burning magnesium approaches more nearly to it than any other, being, according to Pickering, considerably stronger throughout the blue and violet than the light from the Foucault arc lamp. Its color, however, is not reinforced by a violet band like that in the spectrum of the electric arc, a region which, by its extraordinary brightness, has marked influence upon the color of the light.

These variations depend upon temperature primarily, and they may be studied to the best advantage in the spectrum of the incandescent lamp. The radiating surface of such a lamp is at a nearly constant temperature throughout, and it may be given a very considerable range in the matter of incandescence, involving variations in color and total intensity, which are under complete control.

An Edison lamp, similar to that which had been used as a standard in our previous measurements, was subjected to spectrophotometric analysis by Mr. Franklin and myself, at 4 candles, 10 candles, 16 candles, 22 candles and 28 candles, successively. The results obtained are shown in figure 9.

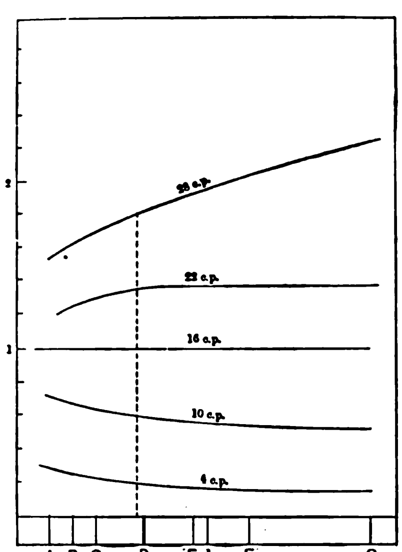

FIG. 9.

The spectrum of the lamp at 16 candles is taken as of unit brightness throughout, and the other curves show the amount of light of each wave length emitted by the lamp in the above-mentioned states of incandescence. Intensities, in every case, are referred to the light of corresponding wave length, given by the same lamp at 16 candles, as unity.

At the red end of the spectrum the intensity increases more slowly than candle-power; at the violet end more rapidly. There exists an intermediate wave length for which the brightness is proportional to the candle-power. The vertical line in the diagram shows the portion of the spectrum for which this holds true, a point in the yellow at wave length 6,000.

14. W. H. Pickering, *l. c.*

15. H. C. Vogel, *l. c.*

16. A. Crova, *l. c.*

If we suppose the same measurements executed upon a set of lamps in every respect similar to the one in question, excepting that their radiating surfaces are of such size that they give 16 candles, as indicated by the Bunsen photometer when the degree of incandescence corresponds respectively to that at which the lamp actually measured emitted at 4, 10, 16, 22, and 28 candles, there would result a set of curves of the same general character as those in figure 12. At wave length 6,000 these curves would have a common value, and they would serve to indicate both the quantity and quality of the variation of the carbon filament, as a function of the incandescence, candle-power remaining constant. The form of these curves is shown in figure 10. They afford us data for discussion of the

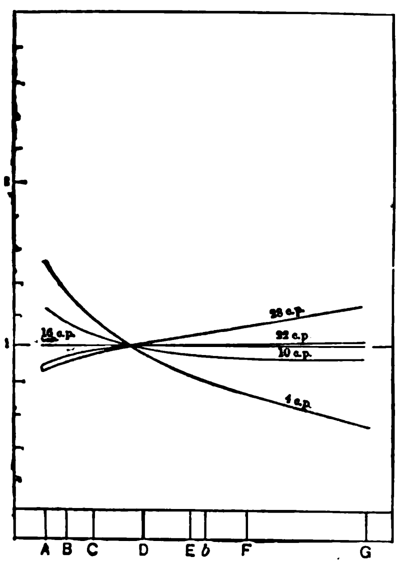

Fig. 10.

candle as a standard of illumination which could not be obtained in any other way. They show the relative distribution of energy in the spectrum of five lamps, which, according to the indications of the Bunsen photometer, are of equal brightness, but which differ both in the quality and in the total energy of their luminous radiation. Their efficiency expressed in terms of the candle-power produced per watt expressed in the lamp, rises rapidly as the incandescence increases. For lamps of the type upon which these measurements were made, for instance, the relative efficiency referred in each case to that of the lamp, the incandescence of which corresponds to that of an Edison lamp at 16 candles, is given in the column headed $\frac{\text{Candle-power}}{\text{Watts.}}$ in table vii.

Table VII.

State of incandescence equivalent to that of an Edison 16-candle lamp giving—	Relative efficiency referred to that of a 16-candle lamp as unity.	
	Candle-power. / Watts.	Luminous radiation. / Total radiation.
(1) 4 candles............	.394	.211
(2) 10 "	.729	.632
(3) 16 "	1.000	1.000
(4) 22 "	1.218	1.368
(5) 28 "	1.391	1.589

If, however, we retain as the measure of efficiency, the ratio, $\frac{\text{luminous radiation}}{\text{total radiation}}$, we can deduce from these curves values coinciding with those reached by the method of the thermopile and alum cell. To this end we must know the above-mentioned ratio for some one candle-power and the number of watts necessary to the production of each state of incandescence for which the computation is to be made.

The relative efficiency can then be calculated from the areas inclosed by the respective curves. Were the candle-power proportional to the energy of luminous radiation, the values thus obtained would be identical with the relative efficiency determined from the relation of candle-power to watts. The relative efficiency thus computed (see table vii.) does not coincide with that obtained from the ratio of watts to candle-power, however, for the reason that the various rays which make up the visible spectrum do not enter into the production of candle-power in proportion to their energy. The most important wave lengths, so far as light-giving power is concerned, are those which form the yellow of the spectrum, and the relative luminosity falls off rapidly both toward the red and the violet. The longer wave lengths have, however, much more influence upon candle-power than the more refrangible rays, as will be seen by an inspection of the curves, the relative falling off of the red end of the spectrum being compensated by larger and larger accessions in the blue and violet as the state of incandescence increases.

Luminosity is the factor, which we must take into account in seeking a complete expression for the efficiency of any source of illumination, and the method to be pursued in the determination of the luminosity must depend upon the use to which the light is to be applied. If we estimate light by its power of bringing out the colors of natural objects, the value which we place upon the blue and violet rays must be very different from that which would be ascribed to them if we consider merely its power of illumination as applied to black and white. In a picture gallery, for instance, or upon the stage, the value of an illuminant increases with the temperature of the incandescent material, out of all proportion to the candle-power, whereas candle-power affords an excellent measure of the light to be used in a reading room.

A number of determinations of the luminosity of artificial light have been made. In the earliest of these by Vierordt,[17] the amount of white light which may be mixed with each color of the spectrum, without producing an appreciable change of tint, was taken as the measure of the luminosity of that color. The result is shown graphically in figure 11. The curve indicates the light-giving

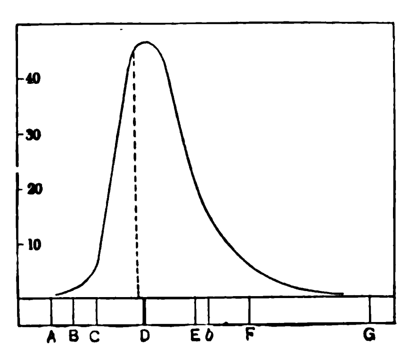

Fig. 11.

power of each wave length, estimated in the above manner. The source of light experimented upon was a petroleum flame. The vertical line indicates the region of the spectrum within which—according to the measurements of the quality of light of the incandescent lamp already described—the increase in the brightness of the spectrum is proportional to the candle-power. This region corresponds very nearly with that of maximum luminosity of the spectrum.

17. C. Vierordt, *Annalen der Physik und Chemie*, Bd. 137, p. 200.

The luminosity of the blue and violet rays is so very small that in the production of *candle-power* the influence of the very rapid growth of this end of the spectrum with increasing temperature of the lamp is scarcely appreciable. If we estimate the light-giving value of the different portions of the spectrum by means of the facility with which we can distinguish black characters upon a white ground, the importance of the more refrangible rays is still farther diminished. Thus Macé de Lepinay and Nicati[18] have shown that if yellow and blue light, estimated to be of equal brightness by photometric means, are of such intensity that one can clearly distinguish a printed page when illuminated by the yellow, the same page will be entirely illegible, when the blue light alone falls upon it. These observers conclude, indeed, that "The mere distinguishing of objects is due almost exclusively to the illumination produced by the less refrangible half of the normal spectrum ;" so that at equal brilliancy "the superiority of yellow sources of light (luminous gas flames, incandescent lamps) over sources richer in blue rays (light of the electric arc) is incontestible." "The only real advantage," they add, "upon the side of the light from the electric arc is when one desires to rehabilitate objects more nearly in the hues which they present in the light of day." This single advantage is one which it is impossible to take due account of, numerically, in an estimate of the efficiency of artificial illumination. It is nevertheless a most important factor in determining the adaptability of a light to nearly all the purposes of everyday life.

Otto Schumann,[19] to whom we owe a most exhaustive study of the light of the incandescent lamp, has determined the luminosity of several types of such lamps at various stages of incandescence. His results, in so far as they apply to a 16-candle Edison lamp, are given in table viii.

TABLE VIII.

Luminosity of an Edison lamp of various stages at incandescence, according to Otto Schumann.

Amperes.	Volts.	Watts.	Luminosity of various regions of the spectrum.						
			Red = λ 676	Orange λ 656	Yellow λ 615	Green λ 557	Blue λ 487	Indigo λ 464	Violet λ 429

I have made these values of Schumann's the basis of a set of curves, by means of which the variation in luminosity, with total energy in watts, is exhibited (see figure 12). It will be seen that the position of the maximum moves slightly towards the violet as the brightness of the lamp increases. This tendency is very slight within the range of temperatures reached by the incandescent lamp. In the arc light we should find the displacement more marked, but in the case of sunlight, in which, as we have seen, the shorter wave lengths are in such preponderance, the movement of the maximum is inconsiderable. The curves shown in figure 13 are taken from the investigation by Crova, who has determined the distribution of luminosities in the spectrum of sunlight and of the flame of a petroleum lamp. The maximum in sunlight is at $\lambda = 582$, that of the petroleum $\lambda = 592$. Nearly all sources of illumination will be found to have a maximum lying between these two wave lengths.

A comparison of the total luminosity of the incandescent lamp with its candle-power shows that the former increases with the energy of the lamp more rapidly than the latter, although the discrepancy is not so marked as in the comparison of efficiency of candle-power with that of luminous radiation.

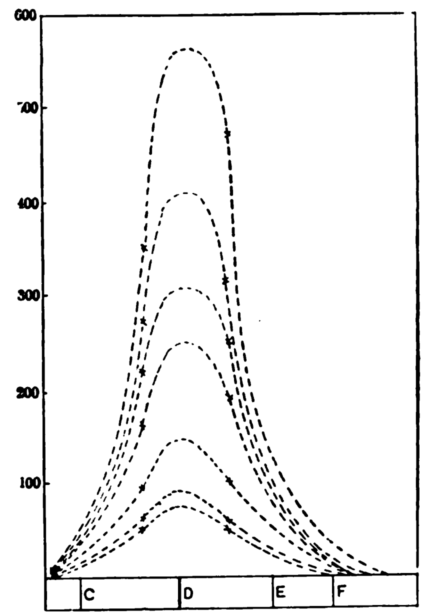

FIG. 12.

The following table, obtained by the summation of the luminosity curves, shows the relation between candle-power and total luminosity, in the case of the lamp studied by Schumann :—

TABLE IX.

Candle-power and total luminosity of the incandescent lamp.

Watts.	Candle-power.	Total luminosity.
54.6	......	4.11
61.3	......	6.31
68.8	10.12	10.20
72.9	12.05	12.58
86.4	18.80	20.64
106.7	31.60	36.80
118.6	41.44	49.77
124.7	50.16	60.85
136.4	64.15	......

Plainly then, candle-power does not afford a measure either of the light-giving energy or of the luminosity of a source of illumination. When used in the comparison of

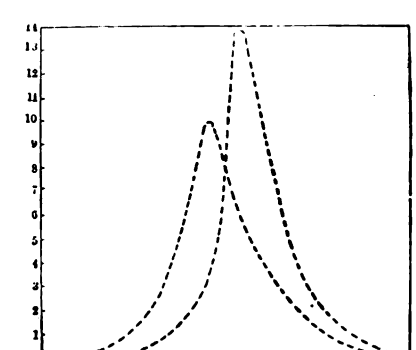

FIG. 13.

sources which differ in temperature, the indications of the photometer always yield us relatively too low a value for the intensity of the lamp of higher incandescence. In the case of candles *vs.* gas, or of either of these in comparison with the incandescent lamp at normal temperature, the

18. Macé de Lepinay and W. Nicati, *Journal de Physique*, second line, T. 2, p. 75, 1883.

19. Otto Schumann, *Elektrotechnische Zeitschrift*, Bd. 5, p. 224, 1884.

error is not important, but between the candle and the "16-candle" lamp maintained at 50 candle-power, the discrepancy amounts to 10 per cent. For the electric arc the ratio of candle-power to total luminosity is very nearly 4 : 5, and in the case of daylight it is about 4 : 6.

In arc light photometry, candle-power is already a well-nigh meaningless term. Would it not be well to abandon it altogether in favor of some standard affording us an expression for the luminosity of radiation? So far as the incandescent lamp is concerned, light-giving power is a perfectly definite function of the temperature and of the area of the radiating surface. We are unfortunately not in position at the present day to measure the temperature of an incandescent filament, but the time will undoubtedly come when the relation between the temperature and the quality of the light emitted by glowing carbon will be definitely known. We may indeed look forward to the development of some optical method for the measurement of the temperature of incandescence which shall be as easily performed as our present method of determining candle-power, and which shall admit of a much higher degree of precision. The comparison of lamps, the temperatures of which are the same, will then reduce itself to a question of radiating surface. Total luminosity and total energy of luminous radiation, per unit of surface, together with net and gross efficiency, may then be expressed, in so far as incandescent carbon is our source of illumination, as functions of the temperature alone, and the performance of any lamp may be defined in terms which admit of no uncertainty.

HERTZ'S RESEARCHES ON ELECTRICAL OSCILLATIONS.[1]

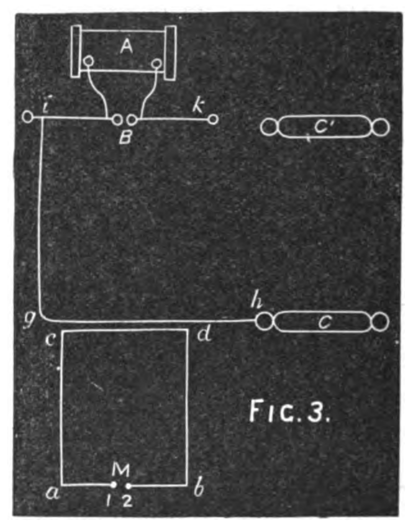
BY G. W. DE TUNZELMANN, B. SC.

(Continued from page 63.)

Induction phenomena in open circuits.—In order to test more fully his conclusion that the sparks obtained in the experiments described in my last paper were due to self-induction, Dr. Hertz placed a rectangle of copper wire with sides 10 and 20 centimeters in length respectively, broken by a short air space, with one of its sides parallel and close to various portions of the secondary circuit of the coil, and of the micrometer circuit, with solid dielectrics interposed, to obviate the possibility of sparking across, and he found that sparking in this rectangle invariably accompanied the discharges of the induction coil, the longest sparks being obtained when a side of the rectangle was close to the discharger.

A copper wire, *i g h* (figure 3), was next attached to the discharger, and a side of the micrometer circuit, which was supported on an insulating stand, was placed parallel to a portion of this wire, as shown in the diagram. The sparks at M, were then found to be extremely feeble until a conductor, C, was attached to the free end, *h*, of the copper wire, when they increased to one or two millimeters in length. That the action of C was not an electrostatic one was shown by its producing no effect when attached at *g* instead of at *h*. When the knobs of the discharger B were so far separated that no sparking took place there, the sparks at M were also found to disappear, showing that these were due to the sudden discharges and not to the charging current. The sparks at the discharger which produced the most effect at the micrometer were of the same character as those described in my last paper. Sparks were also found to occur between the micrometer circuit and insulated conductors in its vicinity. The sparks became much shorter when conductors of larger capacity were attached to the micrometer knobs, or when these were touched by the hand, showing that the quantity of electricity in motion was too small to charge these conductors to a similarly high potential. Joining the micrometer knobs by a wet thread did not perceptibly diminish the strength of the sparks. The effects in the micrometer circuit were not of sufficient strength to produce any sensation when it was touched or the circuit completed through the body.

In order to obtain further confirmation of the oscillatory nature of the current in the circuit *k i h g* (figure 3), the conductor C was again attached to *h*, and the micrometer knobs drawn apart until sparks only passed singly. A second conductor, C′, as nearly as possible similar to C, was then attached to *k*, when a stream of sparks was immediately observed, and it continued when the knobs were drawn still further apart. This effect could not be ascribed to a direct action of the portion of circuit *i k*, for in this case the action of the portion of circuit *g h* would be weakened, and it must therefore have consisted in C′ acting on the discharging current of C, a result which would be quite incomprehensible unless the current in *g h* were of an oscillatory character.



Since an oscillatory motion between C and C′ is essential for the production of powerful inductive effects, it will not be sufficient for the spark to occur in an exceedingly short time, but the resistance must at the same time not exceed certain limits. The inductive effects will therefore be excessively small if the induction coil included in the circuit C C′ is replaced by an electrical machine alternately charging and discharging itself, or if too small an induction coil is used; or, again, if the air space between the discharger knobs is too great, as in all these cases the motion ceases to be oscillatory.

The reason that the discharges of a powerful induction coil gives rise to oscillatory motion is that, firstly, it charges the terminals C and C′ to a high potential; secondly, it produces a sudden spark in the intervening circuit; and, thirdly, as soon as the discharge begins the resistance of the air space is so much reduced as to allow of oscillatory motion being set up. If the terminal conductors are of very large capacity, for example, if the terminals are in connection with a battery, the current of discharge may indefinitely reduce the resistance of the air space, but when the terminal conductors are of small capacity this must be done by a separate discharge, and therefore, under the conditions of the author's experiments, an induction coil was absolutely essentialy for the production of the oscillations.

As the induced sparks in the experiment last described were several millimeters in length, the author modified it by using the arrangement shown in figure 4, and greatly increasing the distance between the micrometer circuit and the secondary circuit of the induction coil. The terminal conductors C and C′ were three meters apart, and the wire

1. From the *Electrician* (London.)

between them was of copper, 2 millimeters in diameter, with the discharger B at its centre.

The micrometer circuit consisted, as in the preceding experiments, of a rectangle 80 centimeters broad by 120 centimeters long. With the nearest side of the micrometer circuit at a distance of half a millimeter from C B C′ sparks two millimeters in length were obtained at M, and though the length of the sparks decreased rapidly as the distance of the micrometer circuit was increased, a continuous stream of sparks was still obtained at a distance of one and one-half meters. The intervention of the observer's body between the micrometer circuit and the wire C B C′ produced no visible effect on the stream of sparks at M. That the effect was really due to the rectilinear conductor C B C′ was proved by the fact that when one or other, or both halves of this conductor were removed, the sparks at M ceased. The same effect was produced by drawing the knobs of the discharger B apart until sparks ceased to pass, showing that the effect was not due to the electrostatic potential difference of C and C′, as this would be increased by separating the discharger knobs beyond sparking distance.

The closed micrometer circuit was then replaced by a straight copper wire, slightly shorter than the distance C C′ placed parallel to C B C′, and at a distance of 60 centimeters from it. This wire terminated in knobs, 10 centimeters in diameter, attached to insulating supports, and the spark micrometer divided it into two equal parts. Under these circumstances, sparks were obtained at the micrometer, as before.

With the rectilinear open micrometer circuit sparks were still observed at the micrometer when the discharger

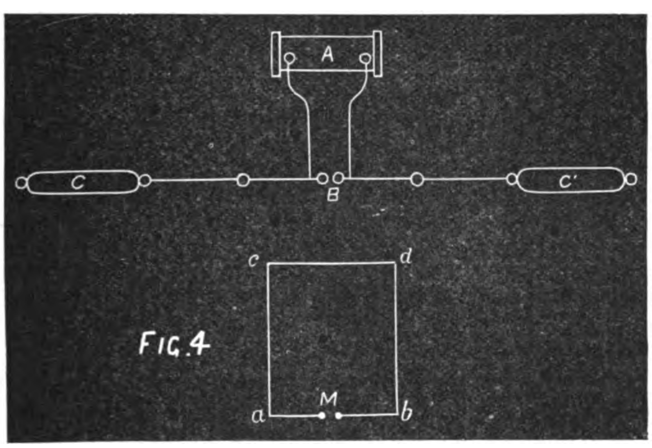


FIG. 4

knobs of the secondary coil circuit were separated beyond sparking distance. This was, of course, due simply to electrostatic induction, and shows that the oscillatory current in C C′ was superposed upon the ordinary discharges. The electrostatic action could be got rid of by joining the micrometer knobs by means of a damp thread. The conductivity of this thread was therefore sufficient to afford a passage to the comparatively slow alternations of the coil discharge, but was not sufficient to provide a passage for the immeasurably more rapid alternations of the oscillatory current. Considerable sparking took place at the micrometer when its distance from C B C′ was 12 meters, and faint sparks were distinguishable up to three meters. At these distances it was not necessary to use the damp thread to get rid of the electrostatic action, as, owing to its diminishing more rapidly with increase of distance than the effect of the current induction, it was no longer able to produce sparks in the micrometer, as was proved by separating the discharger knobs beyond sparking distance, when sparks could no longer be perceived at the micrometer.

Resonance phenomena.—In order to determine whether, as some minor phenomena had led the author to suppose, the oscillations were of the nature of a regular vibration, he availed himself of the principle of resonance. According to this principle, an oscillatory current of definite period would, other conditions being the same, exert a much greater inductive effect upon one of equal period than upon one differing even slightly from it.[1]

If, then, two circuits are taken having as nearly as possible equal vibration periods, the effect of one upon the other will be diminished by altering either the capacity or the coefficient of self-induction of one of them, as a change in either of them would alter the period of vibration of the circuit.

This was carried out by means of an arrangement very similar to that of figure 4. The conductor C C′ was replaced by a straight copper wire 2.6 meters in length and five millimeters in diameter, divided into two equal parts as before by a discharger. The discharger knobs were attached directly to the secondary terminals of the induction coil. Two hollow zinc spheres, 30 centimeters in diameter, were made to slide on the wire, one on each side of the discharger, and since, electrically speaking, these formed the terminals of the conductor, its length could be varied by altering their position. The micrometer circuit was chosen of such dimensions as to have, if the author's hypothesis were correct, a slightly shorter vibration period than that of C C′. It was formed of a square, with sides 75 centimeters in length, of copper wire two millimeters in diameter, and it was placed with its nearest side parallel to C B C′, and at a distance of 30 centimeters from it. The sparking distance at the micrometer was then found to be 0.9 millimeter. When the terminals of the micrometer circuit were placed in contact with two metal spheres eight centimeters in diameter, supported on insulating stands, the sparking distance could be increased up to 2.5 millimeters. When these were replaced by much larger spheres the sparking distance was diminished to a small fraction of a millimeter. Similar results were obtained on connecting the micrometer terminals with the plates of a Kohlrausch condenser. When the plates were far apart the increase of capacity increased the sparking distance, but when the plates were brought close together the sparking distances again fell to a very small value.

The simplest method of adjusting the capacity of the micrometer circuit is to suspend to its ends two parallel wires, the distance and lengths of which are capable of variation. By this means the author succeeded in increasing the sparking distance up to three millimeters, after which it diminished when the wires were either lengthened or shortened. The decrease of the sparking distance on increasing the capacity was naturally to be expected; but it would be difficult to understand, except on the principle of resonance, why a decrease of the capacity should have the same effect.

The experiments were then varied by diminishing the capacity of the circuit C B C′ so as to shorten its period of oscillation, and the results confirmed those previously obtained, and a series of experiments in which the lengths and capacities of the circuits were varied in different ways, showed conclusively that the maximum effect does not depend on the conditions of either one of the two circuits, but on the existence of the proper relation between them.

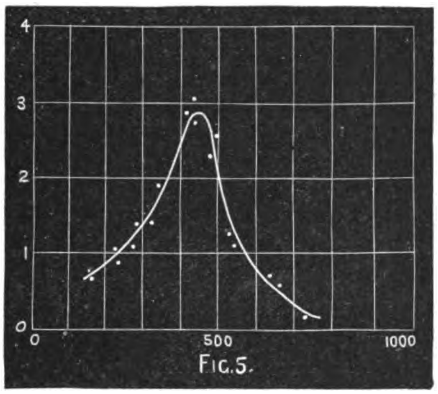
When the two circuits were brought very close together, and the discharger knobs separated by an interval of seven millimeters, sparks were obtained at the micrometer, which were also seven millimeters in length, when the two circuits had been carefully adjusted to have the same period. The induced E. M. F.'s must in this case have attained nearly as high a value as the inducing ones.

To show the effect of varying the coefficient of self-induction, a series of rectangles, *a b c d* (figure 4), were taken, having a constant breadth, *a b*, but a length, *a c*, continually increasing from 10 centimeters up to 250 cen-

1. See Oberbeck, Wiedemann's *Annalen*, vol. xxvi., p. 245, 1885.

timeters; it was found that the maximum effect was obtained with a length of 1.8 meters. The quantitative results of these experiments are shown in figure 5, in which the abscissæ of the curve are the double lengths of the rectangles, and the ordinates represent the corresponding maximum sparking distances. The sparking distances could not be determined with great exactness, but the errors were not sufficient to mask the general nature of the result.

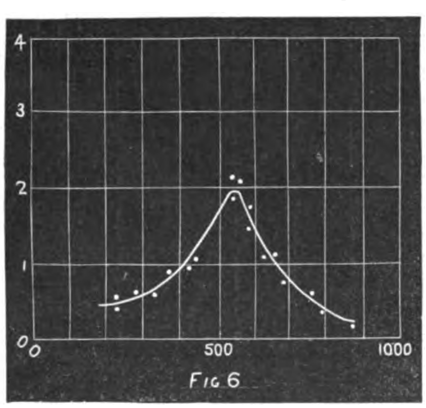
In a second series of experiments the sides *a c* and *b d* were formed of loose coils of wire which were gradually pulled out, and the result is shown in figure 6. It will be



Curve showing relation between length of side of rectangle (taken as abscissa and maximum sparking distance (taken as ordinate), the sides consisting of straight wires of varying lengths.

seen that the maximum sparking distance was attained for a somewhat greater length of side, which is explained by the fact that in the latter experiments the self-induction only was increased by increase of length, while in the former series the capacity was increased as well. Varying the resistance of the micrometer circuit by using copper and german-silver wires of various diameters was found to have no effect on the period of oscillation, and extremely little on the sparking distance.

When the wire *c d* was surrounded by an iron tube, or when it was replaced by an iron wire, no perceptible effect was obtained, confirming the conclusion previously arrived



Curve showing relation between length of side of rectangle (taken as abscissa) and maximum sparking distance (taken as ordinate), the sides consisting of spirals gradually drawn out.

at that the magnetism of the iron is unable to follow such rapid oscillations, and therefore exerts no appreciable effect.

Nodes.—The vibrations in the micrometer circuit which have been considered are the simplest ones possible, but not the only ones. While the potential at the ends alternates betweeen two fixed limits, that at the central portion of the circuit retains a constant mean value. The electrical vibration, therefore, has a node at the centre, and this will be the only nodal point. Its existence may be proved by placing a small insulated sphere close to various portions of the micrometer circuit while sparks are passing at the discharger of the coil, when it will be found that if the sphere is placed close to the centre of the circuit the sparking will be very slight, increasing as the sphere is moved further away. The sparking cannot, however, be entirely got rid of, and there is a better way of determining the existence and position of the node. After adjusting the two circuits to unison, and drawing the micrometer terminals so far apart that sparks can only be made to pass by means of resonant action, let different parts of the circuit be touched by a conductor of some capacity, when it will be found that the sparks disappear, owing to interference with the resonant action, except when the point of contact is at the centre of the circuit. The author then endeavored to produce a vibration with two nodes, and for this purpose he modified the apparatus previously used by adding to the micrometer circuit a second rectangle, *e f g h*, exactly similar to the first (as shown in figure 7), and joining the points of the circuit near the terminals by wires 13 and 24, as shown in the diagram.

The whole system then formed a closed metallic circuit, the fundamental vibration of which would have two nodes. Since the period of this vibration would necessarily agree closely with that of each half of the circuit, and, therefore, with that of the circuit c c′, it was to be expected that the vibration would have a pair of loops at the junctions 13 and 24, and a pair of nodes at the middle points of *c d* and *g h*. The vibrations were determined by measuring the sparking distance between the micrometer terminals 1 and 2. It was found that, contrary to what was expected, the addition of the second rectangle diminished this sparking distance from about three millimeters to about one millimeter. The existence of resonant action between the circuit c c′ and the micrometer circuit was, however, fully demonstrated, for any alteration in the circuit *e f g h*, whether it consisted in increasing or in decreasing its length, diminished the sparking distance. It was also found that much weaker sparking took place between *c d* or *g h* and an insulated sphere, than between *a e* or *b f* and the same sphere, showing that the nodes were in *c d* and *g h*, as expected. Further, when the sphere was made to touch *c d* or *g h* it had no effect on the sparking distance of 1 and 2; but when the point of contact was at any other portion of the circuit the sparking distance was diminished, showing that these nodes did really belong to the vibration, the resonant action of which increased this sparking distance.

The wire joining the points 2 and 4 was then removed. As the strength of the induced oscillatory current should be zero at these points the removal ought not to disturb the vibrations, and this was shown experimentally to be the case, the resonant effects and the position of the nodes remaining unchanged. The vibration with two nodal points was, of course, not the fundamental vibration of the circuit, which consisted of a vibration with a node between *a* and *e*, and for which the highest values of the potential were at the points 2 and 4.

When the spheres forming the terminals at these points were brought close together slight sparking was found to take place between them, which was attributed to the excitation, though only to a small extent, of the fundamental vibration. This explanation was confirmed in the following manner:—The sparks between 1 and 2 were broken off, leaving only the sparks between 2 and 4, which measured the intensity of the fundamental vibration. The period of vibration of the circuit c c′ was then increased by drawing it out to its full length, and thereby increasing its capacity, when it was observed that the sparking gradually increased to a maximum, and then began to diminish again. The maximum value must evidently occur when the period of vibration of the circuit c c′ is the same as that of the fundamental vibration of the micrometer circuit, and it was shown that when the sparking distance between 2 and 4 had its maximum value, the sparks corres-

ponded to a vibration with only one nodal point, for the sparks ceased when the previously existing nodes were touched by a conductor, and the only point where contact could take place without effect on the sparking was between a and e. These results show that it is possible to excite at will in the same conductor, either the fundamental vibration or its first overtone, to use the language of acoustics.

Hertz appears to consider it very doubtful whether it will be possible to get higher overtones of electrical vibration, the difficulty of obtaining such lying not only in the method of observation, but also in the nature of the oscillations themselves. The intensity of these is found to vary considerably during a series of discharges from the coil even when all the circumstances are maintained as constant as possible, and the comparative feebleness of the resonant effects shows that there must be a considerable amount of damping. There are, moreover, many secondary phenomena which seem to indicate that irregular vibrations are superposed upon the regular ones, as would be expected in complex systems of conductors. If, therefore, we wish to compare electrical oscillations, from a mathematical point of view, with those of acoustics, we must seek our analogy in the high notes intermixed with irregular vibrations, obtained say, by striking a wooden rod with a hammer, rather than in the comparatively slow

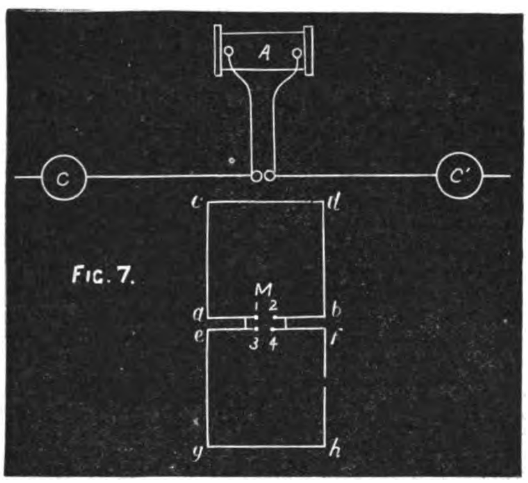


FIG. 7.

harmonic vibration of tuning forks, or strings ; and in the case of vibrations of the former class we have to be contented, even in the study of acoustics, with little more than indications of such phenomena as resonance and nodal points.

Referring to the conditions to be fulfilled in order to obtain the best results, should other physicists desire to repeat the experiments, Dr. Hertz notes a fact of very considerable interest and novelty, namely, that the spark from the discharger should always be visible from the micrometer, as when this was not the case, though the phenomena observed were of the same character, the sparking distance was invariably diminished. This effect of the light from the spark of an induction coil in increasing the sparking distance in the secondary circuit of another coil excited great interest when referred to by Professor Lodge in the course of the recent discussion on Lightning Conductors at the British Association, and he pointed out that the same effect was produced by light from burning magnesium wire, or other sources rich in the ultra violet rays.

Theory of the experiments.—The theories of electrical oscillations which have been developed by Sir William Thomson, von Helmholtz and Kirchhoff have been shown[1] to hold good for the open circuit oscillations of induction apparatus, as well as for the oscillatory Leyden jar discharge, and, although Dr. Hertz has not succeeded in obtaining definite quantitative results to compare with theory, it is of interest to inquire whether the observed results are of the same order as those indicated by theory.

1. Lorentz, Wiedemann's *Annalen*, vol. vii., p. 161, 1879.

Hertz considers, in the first place, the vibration period. Let T be the period of a single or half vibration proper to the conductor exciting the micrometer circuit ; P its coefficient of self-induction in absolute electro-magnetic measure, expressed, therefore, in centimeters ; C the capacity of one of its terminals in electrostatic measure, and, therefore, also expressed in centimeters ; and v the velocity of light in centimeter-seconds.

Then, if the resistance of the conductor is small,

$$T = \frac{\pi \sqrt{P C}}{v}.$$

In the case of the resonance experiments, the capacity C was approximately the radius of the sphere forming the terminal, so that $C = 15$ centimeters. The coefficient of self-induction was that of a wire of length $l = 150$ centimeters, and diameter $d = 1/2$ centimeter.

According to Neumann's formula,

$$P = \iint \frac{\cos \varepsilon}{r} d\,s\,d\,s',$$

which gives in the case considered

$$P = 2\,l \left(\log \frac{4\,l}{d} - 0.75 \right) = 1902 \text{ cm.}$$

As, however, it is not quite certain that Neumann's formula is applicable to an open circuit, it is better to use von Helmholtz's more general formula, containing an undetermined constant, k according to which

$$P = 2\,l \left(\log \frac{4\,l}{d} - 0.75 + \frac{1-k}{2} \right).$$

Putting $k = 1$ this reduces to Neumann's formula, for $k = 0$ it reduces to that of Maxwell, and for $k = -1$ to Weber's. The greatest difference in the values of P obtained by giving these different values to k would not exceed a sixth of its mean value, and, therefore, for the purposes of the present approximation it is enough to assume that k is not a large positive or negative number ; for if the number 1,902 does not give the correct value of the coefficient for the wire 150 cm. in length, it will give the value corresponding to a conductor not differing greatly from it in length.

Taking $P = 1902$ cm. we have $\pi \sqrt{C P} = 531$ cm., which represents the distance traversed by light during the oscillation, or, according to Maxwell's theory, the length of an electro-magnetic ether wave. The value of T is then found to be 1.77 hundred millionths of a second, which is of the same order as the observed results.

The ratio of damping is then considered. In order that oscillations may be possible the resistance of the open circuit must be less than $2\,v\,\sqrt{P/C}$. For the exciting circuit used this gives 676 ohms as the upper limit of resistance. If the actual resistance r is sensibly below this limit, the ratio of damping will be $e^{\frac{r\,T}{2\,P}}$. The amplitude will therefore be reduced in the ratio 1 : 2.71 in

$$\frac{2\,P}{r\,T} = \frac{2\,v}{\pi\,r}\sqrt{\frac{P}{C}} = \frac{676}{\pi\,r} = \frac{215}{r}$$

oscillations. We have, unfortunately, no means of determining the resistance of the air space traversed by the spark, but as the resistance of a strong electric arc is never less than a few ohms we shall be justified in assuming this as the minimum limit. From this it would follow that the number of oscillations due to a single impulse must be reckoned in tens, and not in hundreds or thousands, which is in accordance with the character of the experimental results, and agrees with the results observed in the case of

the oscillatory Leyden jar discharge. In the case of closed metallic circuits, on the other hand, theory indicates that the number of oscillations before equilibrium is attained must be reckoned by thousands.

Hertz compares, lastly, the order of the inductive actions of these oscillations, according to theory, with that of the effects actually observed. To do this it must be noted that the maximum E. M. F. induced by the oscillation in its own circuit is approximately equal to the maximum potential difference at its extremities; for if there were no damping these quantities would be identical, since at any moment the potential difference at the etxremities and the E. M. F. of induction would be in equilibrium. In the experiments under consideration the potential difference at the extremities was such as to give a spark 7 to 8mm. in length, which must therefore represent the maximum inductive action excited in its own circuit by the oscillation. Again, at any instant the induced E. M. F. in the micrometer circuit must be to that in the exciting conductor in the same ratio as that of the coefficient of mutual induction p of the two circuits to the coefficient of self-induction P of the exciting circuit. The value of p for the case considered is easily calculated from the ordinary formulæ, and it is found to lie between one-ninth and one-twelfth of P. This would only give sparks of from $\frac{1}{2}$ to $\frac{2}{3}$ mm. in length, so that according to theory visible sparks ought in any case to be obtained; but, on the other hand, sparks several millimeters in length, as were obtained in the experiments previously described, can only be explained on the assumption that the successive inductive actions produce an accumulative effect; so that theory indicates the necessity of the existence of the resonant effects actually observed.

(*To be continued.*)

THE WIRES MUST GO UNDERGROUND.

Regular meeting of the Board of Electrical Control, Mayor Grant in the chair.

Mayor Grant (to an officer of the electric light company, who is summoned before the Board)—Has your company yet complied with the law requiring them to put their wires in the conduits?

Electric Light Man (innocently)—What conduits?

Mayor—The conduits laid underground to receive them.

E. L. Man (surprised tone)—Have they been laying conduits?

Mayor (sternly)—You know they have.

E. L. Man (suddenly recollecting)—Oh, yes, seems to me I did hear something about it last summer.

Mayor—Your company has promised repeatedly to bury the wires.

E. L. Man (with a puzzled look)—Bury what wires?

Mayor (impatiently)—Your electric wires, of course.

E. L. Man—Bury them before they are dead?

Mayor (with rising indignation)—We'll have no more trifling in this matter.

E. L. Man—I never trifle with an electric wire, especially when it is alive, your Honor.

Mayor (consulting his notes)—Over a year ago you were given sixty days to put your wires underground. Why didn't you do it?

E. L. Man (after reflecting)—I think it rained.

Mayor—Then your time was extended sixty days more. Why wasn't it done then?

E. L. Man—Why wasn't what done?

Mayor (emphasizing each word by a tap of his pencil on the table)—Why—didn't—you—put—the—wires—under—ground?

E. L. Man—Oh, why didn't we? Well, we didn't know that they wanted to be put underground.

Mayor (getting mad)—We'll have no more fooling; the poles must come down.

E. L. Man—What poles?

Mayor—Don't your company have poles?

E. L. Man—Oh, yes. Now and then one, more for ornament than anything else.

Mayor (getting ugly)—Well, if those poles are not down and the wires underground in thirty days I will know the reason why.

The Electric Light Man bows and saunters off, satisfied that there's no occasion to hurry about it.—*Texas Siftings.*

POINTERS.

.... LIGHT and power are the foundation necessities of civilization.—*A. R. Foote.*

.... I BELIEVE that nine out of ten workmen, if they are not watched, will make bad joints.—*W. A. Chamen.*

.... ELECTRICAL engineers know well that they must, before all, be engineers. They must be engineers, and they must learn electricity.—*Sir William Thomson.*

.... WITH regard to the insulation of slate bases and fittings, I find that slate may be greatly improved in this respect by soaking it in melted paraffine wax.—*G. C. Fricker.*

.... PORTLAND cement certainly seems to have some deteriorating effect upon insulation.—*W. A. Chamen.*

.... WHAT limits may be found on the practical distribution of electric power is not known. Conditions for its distribution are being learned. When the natural laws governing it are complied with in these conditions, it is known that the world is not large enough to limit its distribution.—*A. R. Foote.*

.... WHAT is chiefly wanted is to ascertain the minimum standard of insulation resistance compatible with good honest work and ordinary careful usage.—*Professor A. Jamieson.*

.... THE limit of the benefit derived from the use of any force is fixed by the power to distribute it cheaply. Of the two factors, the power to *distribute* cheaply is far more potent than the power to *produce* cheaply.—*A. R. Foote.*

.... THE total insulation of a self-contained installation containing a dynamo need not be nearly so high, and consequently need not be treated so carefully, as that of one forming part of a central station system.—*R. E. Crompton.*

.... ELECTRIC light and power will produce more changes in the mechanical servants and conveniences of civilized life than has ever been caused by the use of any other method or force which has been subjected to the service of man.—*A. R. Foote.*

.... THE electrical engineer, or the youth or aspirant to that honorable profession, after having obtained the elements of a good general education, ought to learn mathematics and dynamics well. Then a good deal of chemistry and regular mechanical and civil engineering should all be learned; and electricity besides.—*Sir William Thomson.*

.... IGNORANCE more frequently begets confidence than knowledge; it is those who know little and not those who know much, who so positively assert that this or that problem will never be solved by science.—*Darwin.*

.... IT is no longer a difficult matter to obtain high insulation in every part of dynamo machines. Now that we dynamo makers have had our attention directed to the fact that there are far better varnishes than shellac, there is no difficulty in obtaining any desired degree of insulation on the dynamo itself, from the first moment that it is wound.—*R. E. Crompton.*

.... A FORCE is known by its highest form of expression. Water power is mentioned without reference to the power of gravity. Steam power is referred to without reference to the expansive power of water or heat. Electric power is also spoken of without reference to its underlying forces. It is vitalized by all power. It is the spirit of all force.—*A. R. Foote.*

.... EVERY requirement of sound business management demands that those who build for an investment, shall use only the best apparatus and material for its purpose, and shall construct in the most durable and artistic manner.—*A. R. Foote.*

.... EVERY young person who has a fancy for electricity thinks he would like to be an electrical engineer. He thinks electrical engineering is all ether and electricity. Now I have continually to impress upon anxious fathers and mothers that their boys must condescend to learn something of gross ponderable matter, and that electrical engineering is not confined to ether and electricity, but mechanics also is an essential part of the subject. —*Sir William Thomson.*

.... IT is quite easy, if due precautions are taken, to obtain excessively high insulation on installations of considerable magnitude.—*R. E. Crompton.*

.... THE advent of a new force has never completely abolished the use of the old. In fact, the new is developed by making the old its servant. Water became the servant of steam. Water and steam are the servants of electricity.—*A. R. Foote.*

THE WESTERN ELECTRIC COMPANY'S NEW BUILDING IN NEW YORK.

The New York branch of the Western Electric Company has just been housed in the factory and store building recently completed at the corner of Greenwich and Thames streets. In elegance of appearance, in solidity, and in adaptation to the several requirements of factory, warehouse and offices, the structure may fairly be said to embody the best that skill, knowledge and taste, well supported by wise and liberal expenditure, can devise at the present time.

Since the spring of 1879, when the Western Electric Company established a New York branch through the acquisition of the factory and repair shop of the Western Union Telegraph Co., it has, till the present removal, occupied, on lease, the Western Union factory building on Trinity place (New Church street). Some years ago the steady expansion of the business, both in manufacturing and trading, had made it clear to the officers and directors of the company that provision would soon have to be made for greater facilities. After careful and well matured consideration it was determined to seek a location in the down-town business section not remote from the old factory, and to put up a thoroughly high-class building large enough to permit still further expansion of the works. It became necessary, therefore, to resort to height rather than to a spacious ground plan for obtaining the requisite amount of floor space. How well all has been accomplished will appear, to some extent, in the following description, with the illustrations showing a view of the exterior of the new building and plans of several of the floors.

The Western Electric Company's Building, New York.

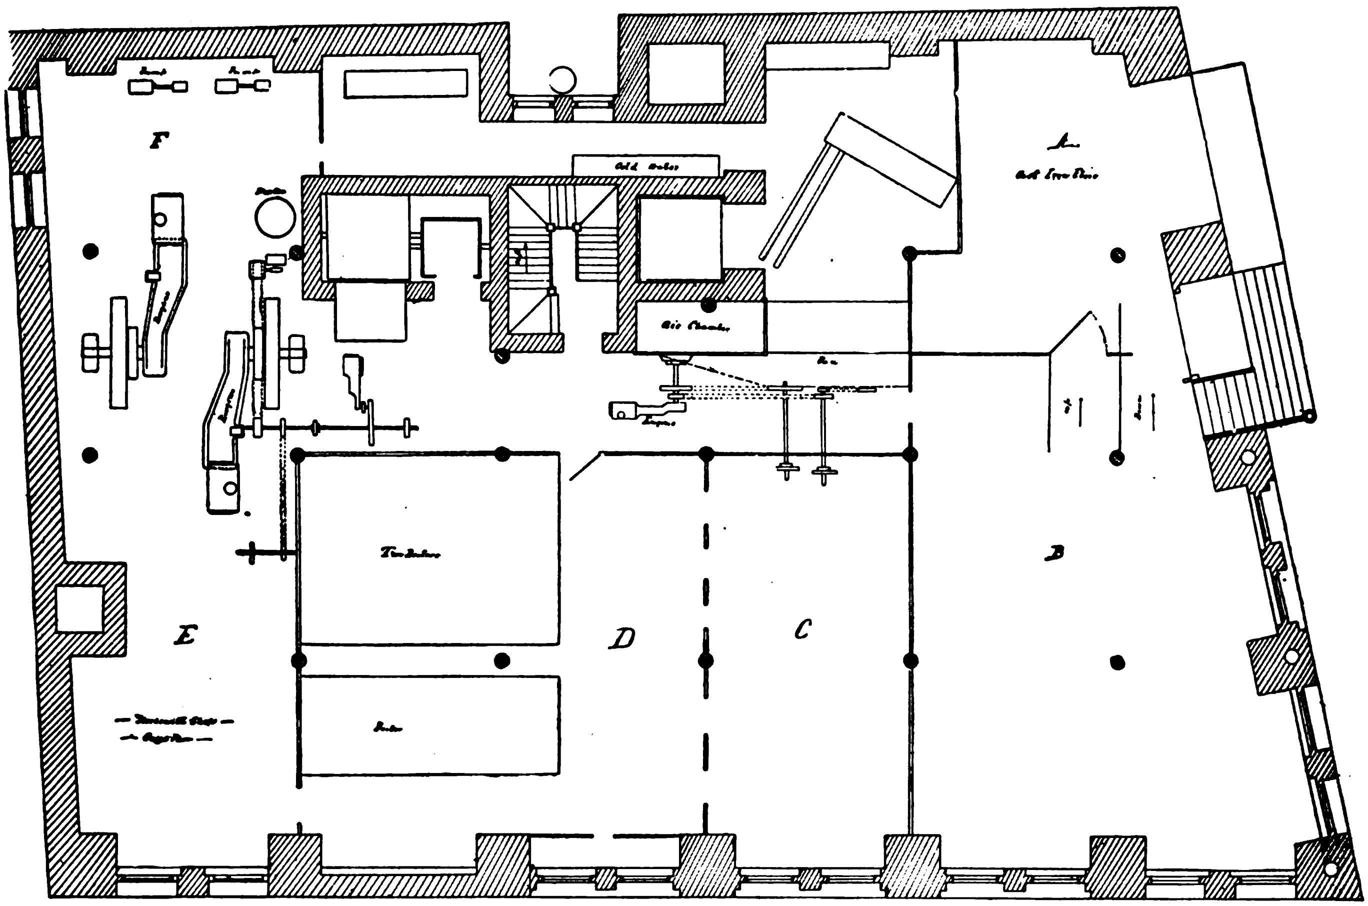
The building has 119 feet frontage on Thames street and 83 feet frontage on Greenwich street. In March, 1888, the ground was occupied by tenement houses, in which there were about fifty families living. About the 1st of April work was commenced, tearing down the old buildings, and in May the work of putting in the foundations was begun. The work on the foundations was delayed by the necessity of shoring up the adjoining buildings, and it was about the 1st of August before any work could be done on the superstructure. By the 1st of November, however, the building was ready for the roof beams; this remarkably quick progress of the building being due largely to the energy of the architect and of Mr. Otto Eidlitz, of Marc Eidlitz & Son, the builders.

The handsome appearance of the building, and the thorough construction of it, are due to the architect, Mr. C. L. W. Eidlitz. Its convenient arrangement for the purposes of the Western Electric Company is largely the work of Mr. W. R. Patterson, of the Chicago house, who, in planning the arrangement of the Chicago shop, gained an experience which admirably fitted him for this work.

The building is as nearly fire-proof in construction as possible, the columns, girders and beams being of iron, and the floors of brick and concrete, covered with one layer of maple. The stairway and elevators are separated from the rest of the building by brick walls and iron doors. In addition to this fire-proof construction the precaution was taken of fire-proofing all of the iron work on the lower floors, in which the wood-working department, store rooms, etc., are located, and of building a fire-proof vault on each floor for the storage of records, tools, patterns, and, especially, valuable finished goods. The principal contractors in the construction of the building were Marc Eidlitz & Son, masons and builders; Post & McCord, iron work; and Thomas Wilson, wood work.

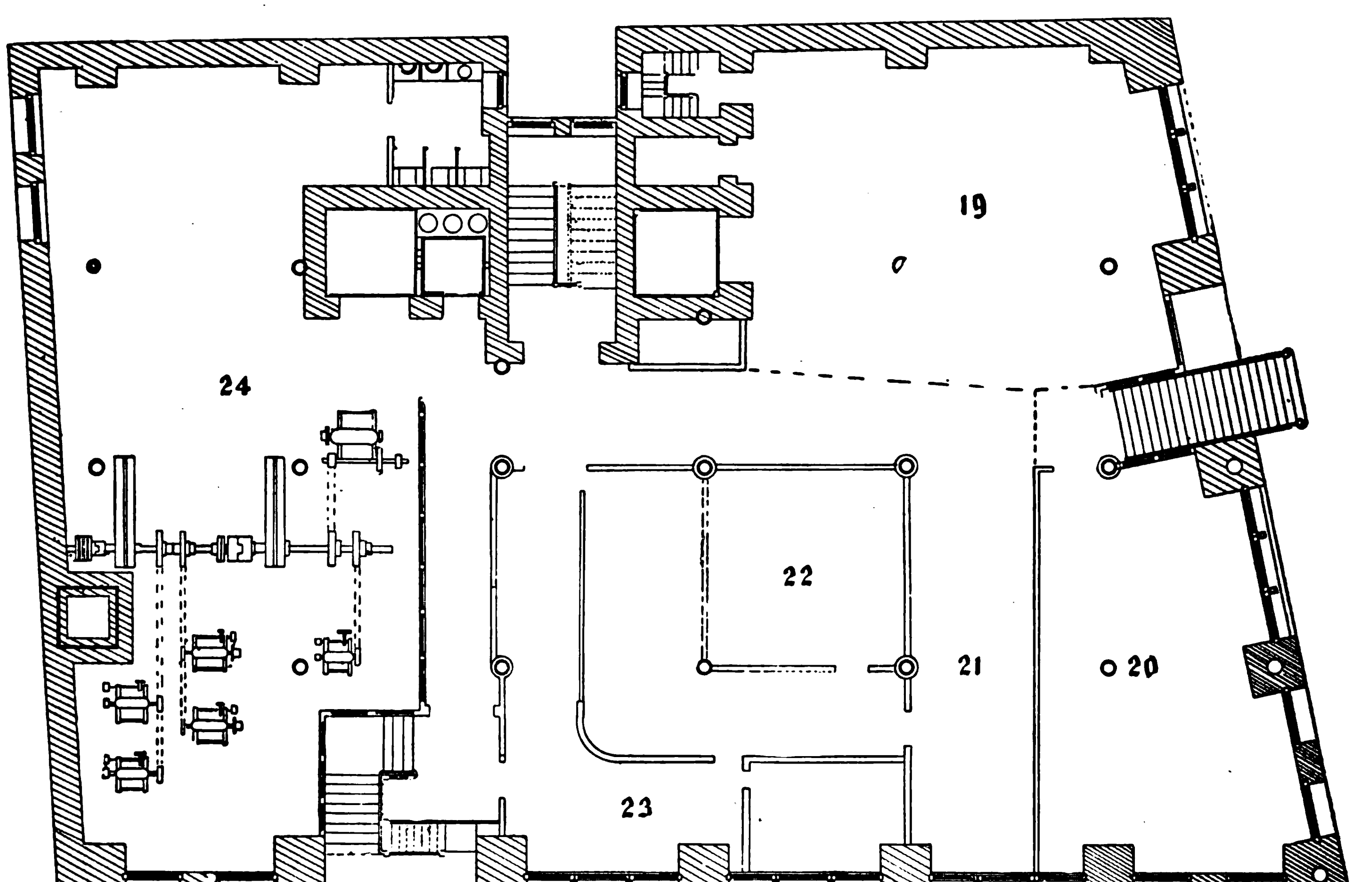
The exterior of the building is of buff brick, of the shade known as Telephone brick, which was used in the construction of the Telephone Building on Cortlandt street. This brick, together with the terra cotta, was furnished by the Perth Amboy Terra Cotta Co.

The entrance to the offices and to the retail store is on Thames street; on Greenwich street is the shop entrance and also the platform for shipping and receiving goods. (See plan of second floor.)



WESTERN ELECTRIC COMPANY'S BUILDING.—BASEMENT (FIRST FLOOR).

A. Foundry Store Room.
B. Foundry.
C. Coal Storage.
D. Boiler Room.
E. Blacksmith Shop.
F. Engine Room.



WESTERN ELECTRIC COMPANY'S BUILDING.—SECOND FLOOR.

19. Packing Room.
20. Nickel-Plating Room.
21. Cable Work Room.
22. Electric House Work Room.
23. Retail Store.
24. Dynamo Room.

In December the building was ready for the steam plant. This consists of three Babcock & Wilcox boilers, two in battery, capable of developing 312 h. p.; and a separate boiler capable of developing 136 h. p. (See plan of basement—first floor.)

The power plant consists of two engines, with cylinders 18 inches in diameter by 27 inches stroke, which, at 125 revolutions per minute, will each develop 175 h. p. Also, one engine with cylinder eight inches in diameter by 12 inches stroke, 35 h. p. The three engines were from Russell & Co., Massilon, O. The power is transmitted to the various floors by rope transmission furnished by the Link Belt Machinery Co., of Chicago; the rope used being made of rawhide. The engine room is equipped with all of the latest improvements in the way of feed-water heaters, pumps, regulators, eliminators, etc.

The heating plant of the building was furnished by B. F. Sturtevant, of Boston, and consists of a heating chamber in the basement, a blower 10 feet by five feet, and a Sturtevant engine, cylinder eight inches in diameter by 12 inch stroke. Cold air is drawn to the heating chamber through a duct terminating three feet above the roof. After passing through the heating chamber it is blown through a hot air duct having openings on the various floors.

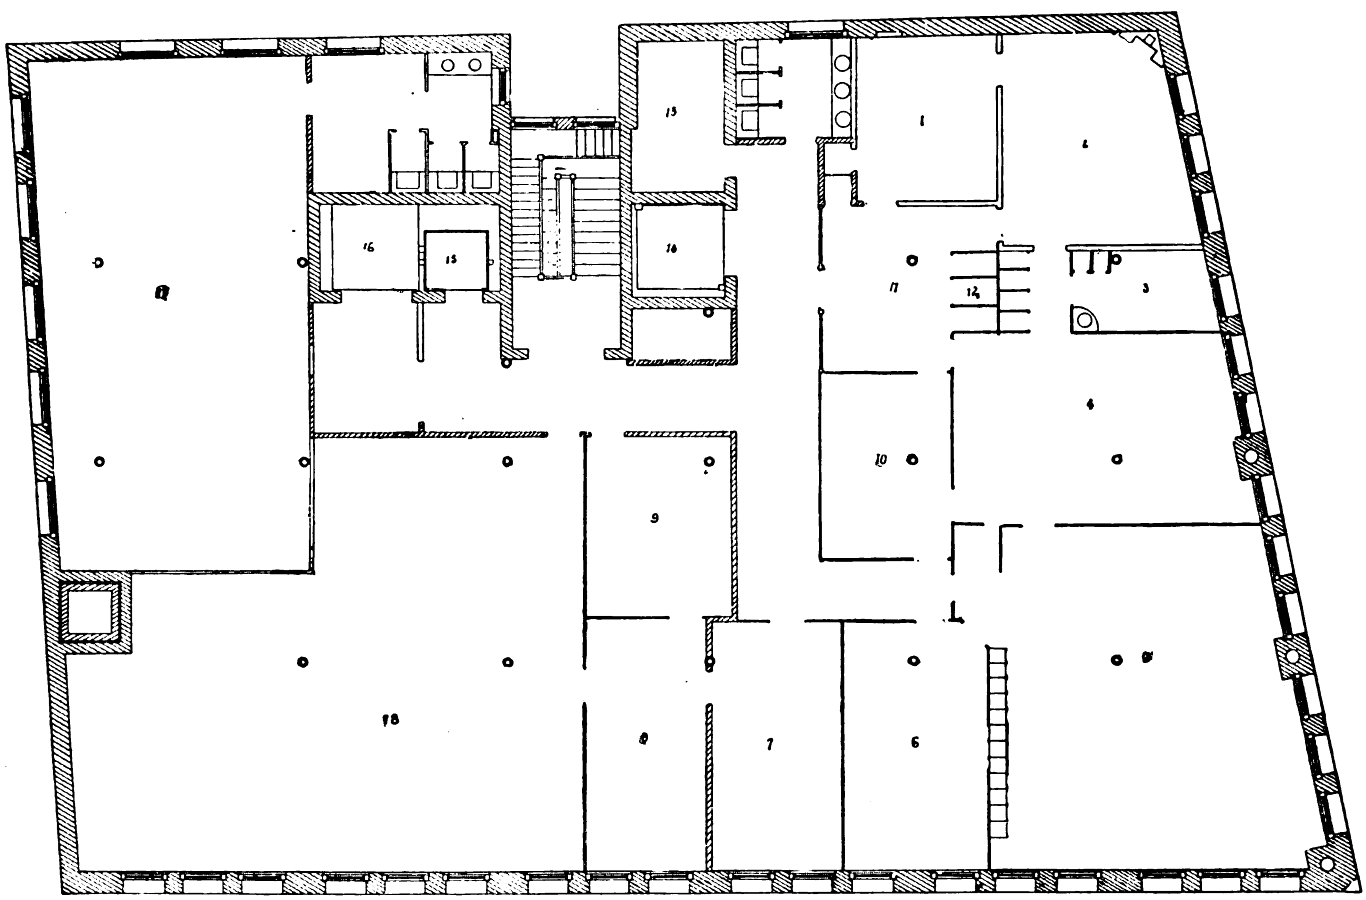
The building is furnished with two worm geared freight elevators and a steam passenger elevator, put in by the Crane Elevator Co. The east freight elevator is for the use of the shop, carrying material and unfinished work from one floor to another; the west freight elevator is intended for the use of the shipping department.

Besides the boiler and engine room there are in the basement (first floor) a blacksmith shop and foundry. Between the basement and the second floor there is, on the Greenwich street side, an intermediate floor at the level of a truck above the sidewalk, to facilitate the shipping and receiving of goods. Directly above it, on the second floor, is the packing room. On this same floor are the nickel plating room, the cable department work room, the retail store, and the electric house work department.

The whole space to the left of the Thames street entrance, which leads directly to the passenger elevator communicating with the offices, is the dynamo room. Here are three 45-light and one 35-light arc dynamos and a 300-light incandescent dynamo, all manufactured by the Western Electric Company, and to be used in lighting the building. On this floor, also, is the main shaft, and the outfit of clutches, so arranged that any one of the four engines in the basement, or any combination of them, can be used for the power, light, or heat which may be necessary.

The third floor is occupied by the wood-working department and by the battery room and chemical laboratory. The fourth floor is used entirely for storage of the various line and other electrical supplies sold but not manufactured by the Western Electric Company. On the fifth floor is the shop office and shop storeroom, and some of the heavier machinery, such as presses, screw machines, planers and engine lathes. The sixth, seventh and eighth floors are for general manufacturing. The ninth floor is used in part for the manufacture of telephones, and in part for inspector's room, where all of the apparatus manufactured is inspected before shipment, and where manufactured goods are stored until shipped.

The eastern half of the tenth floor is occupied by the winding room (in which electro-magnets for the various instruments are wound) and by the work room for the switch-board department. The western half of the tenth floor is occupied by the offices of the New York branch of the company. (See plan of tenth floor.)



Western Electric Company's Building.—Tenth Floor.

1. President's Room.
2. Manager's Room.
3. Stenographers.
4. Salesmen.
5. Counting Room.
6. Cashier's Room.
7. Cable Department.
8. Switch-board Department.
9. Library.
10. Mailing and Filing Room.
11. Waiting Room.
12. Telephone Closets.
13. Fire-Proof Vault.
14. Freight Elevator.
15. Passenger Elevator.
16. Freight Elevator.
17. Winding Room.
18. Switch-board Work-room.

The building is thoroughly equipped with everything in the way of electrical apparatus which facilitates the transaction of business. The various offices and floors are connected by the Western Electric speaking tube telephone system, by means of which connection can instantly be made between one room and another without the aid of a central office or switch-board. In the waiting room of the general office are three telephone closets, in one of which is one of these speaking tube telephones, and in the other two a long-distance telephone instrument and a metallic circuit city telephone.

A room opening out of the offices is being fitted up as a library, where there will be as complete a collection as possible of books and periodicals for the use of the employés

The location of the offices on the top floor of the lofty building is characteristic of the excellent judgment shown in the arrangement of the entire structure. The tenth floor is so far above the street level as to secure to the staff and clerks immunity from the noise and dust of the crowded thoroughfare below, and it is so high above the neighboring roofs that abundant sunlight and air has access on every side. The room occupied by the manager, Mr. H. B. Thayer, at the south-west corner, and the adjoining room—for the use of the president, Mr. E. M. Barton, and the secretary and treasurer, Mr. J. M. Jackson, when in New York—can hardly be surpassed in the city for their outlook over the surrounding town, waterways and country. The rooms of the purchasing agent, cashier, heads of departments, salesmen and clerks are hardly less pleasant, and are very commodious and handsome in their appointments.

The work rooms, most of them being on the upper floors, are unusually well provided with air and light for a factory situated in the down-town district.

This elegant and thoroughly equipped building, with the large and still growing business now to be conducted within its walls, must be regarded as an important contribution to the industrial growth of New York.

ABSTRACTS AND EXTRACTS.

THE RIVAL ALTERNATING CURRENT DISTRIBUTING SYSTEMS IN LONDON.

Being, as we believe, on the eve of a great development in central station work, it may be useful to review briefly the present position of this industry. The generation of electricity, and its utilization in suitable lamps, are problems which are now satisfactorily solved, but its transmission from the station to the customers' houses and its storage are still open questions, and various rival systems are now, or shortly will be, clamoring for public favor. It is an easy matter to determine the merits of any particular dynamo, battery, motor, or lamp; but problems connected with the distribution of current throughout an extended district cannot be solved in the laboratory or the workshop, and a solution to such problems can only be found by experiments on a large scale. Such experiments are very costly, and, if unsuccessful, must entail an enormous amount of inconvenience on the users or would-be users of the electric light. In alternate current distribution there are now, broadly speaking, two rival systems in the field—the one modeled on the method of supply adopted by large gas companies, and the other an extension of the plan adopted in low tension direct current stations. In the first system the current required for the whole district is generated at a single gigantic station situated outside the area to be lighted, whilst in the second system this area is sub-divided into several sections, each having its own central station, either within its own boundary or as close to it as possible. Both these plans are to be tried in London—the first by the London Electric Supply Corporation, Limited, whose Deptford station will form a counterpart to the Beckton Gas Works; and the second by the Metropolitan Electric Supply Co., Limited, who also propose to serve the whole of London, but from many smaller central stations, so distributed that the maximum distance to any customer should not exceed about a mile. There are reasons for and against each of these plans. In the Deptford scheme the whole of the generating plant is concentrated in one locality, and the cost of working and supervision is thereby reduced. Moreover, the locality chosen has river frontage, and fuel can therefore be obtained at the cheapest possible rate. It has the further advantage of being sufficiently isolated to be practically free from the danger of causing annoyance to neighbors—a consideration of some importance. Legal proceedings against electric light companies, on the ground of annoyance to neighbors by reason of vibration, noise and smoke, are unfortunately not unknown in this and other countries, as shown by the examples of Paddington, Liverpool, Vienna, Paris and other places; and the Deptford works will, at any rate, be spared the annoyance of legal proceedings from ill-disposed neighbors. On the other hand, the selection of a site so far away from the districts where most of the profitable lighting can be done, has the disadvantage of either entailing a very heavy outlay for mains, or necessitating the adoption of a pressure which is largely in excess of anything hitherto attempted. Mr. Ferranti, the company's engineer, has chosen the latter alternative, and devised a type of main which may reasonably be expected to carry the standard pressure of 10,000 volts determined upon with safety; but until this expectation has been verified by actual experience, the necessity of employing so high a voltage is certainly one of the strongest reasons against the plan of concentrating all the power in one single centre. The Deptford scheme has also been criticised on other grounds, notably on account of the gigantic engines and dynamos which will there be used. One of the larger dynamos will supply some 200,000 lamps, and there are many electricians who hold that the risk involved is too great to compensate for any slight advantage in economy which may be expected from the increase in the size of the engines. The risk, of course, is that of the extinction of the whole of the 200,000 lamps, should anything go wrong with the dynamo or its two 5,000 h. p. engines. These are of the marine type, and in estimating the probability of an accident we are justified in looking to marine practice for precedents. What are the facts? Engines of that class are working in Atlantic liners at full power for six, seven or eight days without a moment's interruption, and a breakdown during the voyage is a very rare occurrence. Now, in electric lighting, these engines will not be worked at full power for more than a few hours daily, and during the rest of the time they will work at half or quarter load, or will stand idle. In planning the Deptford station the engineer has, in fact, provided for a complete set of spare machinery, so as to allow ample time for overhauling the engines and dynamos daily; and with the special apparatus designed to facilitate examination, there will be no danger of this being neglected. We may, therefore, take it that a breakdown from want of supervision and examination is almost an impossibility. If the engine of a steamer which must work at full power for a week, and can only be overhauled at long intervals, can be relied on, it is evident that an electric light engine, which can be overhauled daily, must at least be equally reliable. It might, however, be objected that, let the probability of a breakdown be as remote as you will, an accident is sure to happen now and then, and that even the engines of the Atlantic steamers are not exempt from this failing. This, no doubt, is true, and by analogy we must expect an occasional breakdown in electric light engines; but where a complete set of spare plant has been provided, the interruption to the lights can only last during the brief time required to throw the load from the disabled set of engines and dynamo to the reserve set. A piece of carefully designed machinery

does not break down without previous warning, and in most cases there will be sufficient time to start the reserve set before the working set must be stopped; so that the time occupied in the transfer of the load, that is, the time during which the lights will be out, need not occupy many seconds.

But even an extinction of light lasting only a few seconds is objectionable, and it is in this respect that the programme which the consulting engineers to the Metropolitan company have elaborated is specially attractive. Mr. Gordon, the company's engineer, does not believe in gigantic machines supplying current at 10,000 volts. He objects to the plan of putting too many eggs into one basket, and prefers to sub-divide the power into smaller units, even at the cost of greater complexity of the plant, and the consequent increase in the cost of supervision. According to the present arrangements, the capacity of each of the company's stations is to be about 500 kilo-watts, corresponding to the supply of ten thousand 16 c. p. lamps simultaneously alight, and the district is to be limited to a radius of about one mile from the station, the standard pressure being 1,000 volts. The consulting engineers are confident that it will be found possible not only to couple the dynamos at one station in parallel, but also the dynamos between the different stations, a feat which has been already performed in America, where two Westinghouse stations lying on opposite sides of a river are so connected, if the demand for current on one station exceeds its capacity. If these anticipations can be realized in everyday practice, the plan of sub-dividing the generating plant into comparatively small units will give absolute immunity from extinction of light, which might otherwise be brought about by a breakdown of an engine or dynamo; and in this respect the distribution will be as certain and continuous as in any of the low tension direct current Edison stations, which have now satisfactorily stood the test of years. The system has, however, also another advantage. When it is possible to run alternators in parallel, the number of machines kept simultaneously at work can be arranged to correspond to the output required; that is to say, no engine or dynamo need be worked very much under-loaded, and consequently the machinery at a station will, during the whole of the twenty-four hours, work with almost maximum efficiency.

The earning capacity of a central station is largely increased by its ability to sell power as well as light, and in this respect low tension direct current stations have hitherto possessed a decided advantage over any station supplying laternating currents. The Edison central stations in Boston, New York, Berlin and other large towns are doing a very profitable business in the supply of current for power purposes, and there can be little doubt that the above mentioned alternate current supply stations could do a very excellent business in the supply of power in many London districts, if only a suitable motor could be found. Two years ago this problem appeared to be an almost hopeless one, but at the present time, thanks principally to the investigations of Professor Ferraris, of Turin, we are within a measurable distance of its solution. We learn that a Swiss electrician in the early part of this year produced a serviceable motor, and that the apparatus devised by Mr. N. Tesla has, in the hands of the Westinghouse company, been developed into a practical machine. Messrs. Ganz & Co., of Budapest, are also busy with this problem, and have so far been successful as to produce a motor giving 66 per cent. efficiency. To judge from what has been accomplished in this direction within the short space of a year, we may confidently expect that the time is not far distant when the supply of motive power will, even with alternate current stations, be an important source of revenue. —*Industries.*

.... THE demonstration is now complete, that all the illuminating and power service of a city can be performed from one central station. Every consideration of economic advantage requires that it shall be done.—*A. R. Foote.*

DISCUSSION ON LIGHTNING CONDUCTORS AT THE BRITISH ASSOCIATION.[1]

(Continued from page 586, vol. vii.)

SIR WILLIAM THOMSON said that, with respect to the very marked difference between Professor Lodge and Mr. Preece, he might say that he considered Professor Lodge to be in the American stage with reference to the judging of the functions of inertia, and Mr. Preece to be rather in the English state, as described on Friday by Professor Ayrton. The functions of inertia were to prevent anything getting into motion, and when in motion, to keep it going; and both these functions are perpetually being performed in this electrical influence. He could not but think that if Professor Lodge continued his work, he would find the explanation of the discovery he had made, that iron wire affords an easier path in the circumstances that he has minutely defined than does copper. He hoped that Professor Lodge would continue his investigations, keeping the circumstances in all respects as similar as possible, comparing, for example, a thin iron wire with a thin wire of lead or brass of the same ohmic conductivity. Professor Lodge had done a good deal already, but a good deal more might be done by taking proper account of inertia, and of the other point that Professor Lodge had very properly accentuated—that the energy must be got quit of somehow and somewhere. If it were got rid of in the conductor, then there must not be energy enough to melt tne conductor. It was an interesting fact about the number of people in a row, where the extremes felt the discharge, while the intermediate ones did not. There was one very marked influence here, and that was want of perfect insulation; but there was another influence, also potent —self-induction. The influence of self-induction might be tried, and it would be a very interesting experiment. He thought they might try this same thing with as nearly as possible similar insulation with the same number of people spread out in a large circle. Then self-induction would be much more influential in causing the discharge not to keep through the line of the comparatively good conducting bodies, but to spread through the floor or ground under them. Take the case of persons ranged in a row and receiving an electric shock. If the row is zig-zag, then self-induction will not have the same tendency to cause the lightning discharge to leave the line of the best conductors, as it will have if the conducting bodies are placed in a wide circle. He believed the imperfect insulation of standing on the floor would be much more potent, and he should expect that those who were in the middle of the row would experience less of the shock in the case of standing in a wide circle than in the case of standing on similarly good conducting material in zig-zag rows. At all events, that was an experiment worth repeating. Mr. Preece had spoken of the impossibility of conceiving of the enormous augmentation of potential in these actions. Take the name "inertia," which Mr. Preece used; he fully agreed in the judiciousness of that term. Apply the word "inertia" to the steam hammer and the hydraulic ram. You begin with a comparatively gentle force, its weight bringing down the steam hammer, till it produces an exceedingly intense action at the blow. Take the hydraulic ram, the well-known analogue for getting up a high potential for self-induction in an electric circuit, and then, he thought, they would see that Professor Lodge's explanation of the phenomena he had brought before the meeting was altogether valid. He thought Mr. Preece was quite right in speaking of the multiplicity of flashes of lightning. He had given some unmistakable experimental and observational evidence of it which agreed very well with what he himself had noted. The first time that he distinctly remembered noticing it was in the summer of 1840, at Frankfort, where he had the pleasure of seeing a great many thunderstorms. He then remarked triple and quadruple flashes frequently, but at such short intervals of time that one could not but think that they were in some way connected, and yet at long enough intervals to allow him quite distinctly to see that they were not one flash, but several flashes. As Mr. Abercromby had said, it did not seem to be repetition of flash along one and the same course, but a succession of connected flashes. One flash seems to cause many others. Light had been spoken of—the light of one flash tending to produce another flash. It seemed that the very fine oscillations of light actually put the air into a condition which was more easily disrupted than air which is not agitated by light; but that would not account for the time interval between the different flashes which was spoken of by Mr. Preece, and which he himself had noticed repeatedly. He thought this might depend on the velocity of propagation of sound in the air. The first flash did produce certainly a tremendous disturbance in the air. He thought that they could not account for an electric flash through air otherwise than by supposing a crack in the air suddenly filling up and producing an exceedingly sharp elastic disturbance. It was quite possible that that elastic disturbance propagated at a rate nearly equal to the ordinary velocity of sound to another place where the air is in a state of high tension, ready to break down, caused it to break down. Thus it might be that one flash caused a considerable

---

1. From *Industries*, November 23, 1888.

number of others at intervals of a quarter of a second, or a few quarter seconds, from its initiation. This was a thing that might be experimented upon.

Sir William Thomson then went on to suggest a plan whereby the simultaneity of flashes might be tested—proposing to use several cameras, each having before it a revolving shutter with a hole in it. These shutters were to be arranged so that, all revolving at the same speed, each was to be in advance of the next; so that no two cameras should be simultaneously open for exposure, and yet *one* plate should always be exposed during the whole period of duration of a flash. He then went on to discuss the question of the possibility of magnetization being effected by an oscillatory discharge. Reis had, he said, some time prior to 1853, experimented on the subject, and had magnetized steel needles by the discharge of a Leyden jar. He found that sometimes these needles were magnetized in the direction that would be expected from the direction of the main charge, and sometimes in the opposite direction. He (the speaker) believed, as Lord Rayleigh had stated, that experimenters had actually found differences of direction of magnetization in different individuals of a group or bundle of steel wires thus actuated, or rather thus exposed to this kind of magnetizing action. If they had a very powerful current going in one direction, followed by a current of half that strength going in the opposite direction, a current of a quarter the original strength going in the first direction, and so on, then they might expect the needle to be left magnetized by the current going in that one direction, corresponding to the last time that it had magnetizing force enough to magnetize or to reverse the magnetization of the needle. So that he thought by repeating Reis's old experiment with the same degree of electro-magnetic inertia in different successive cases, but with different degrees of ohmic resistance, and, therefore, different rates of extinction of the oscillation, probably a full investigation might be made. It was rather disturbing to find that a lightning rod had so little protecting power as, according to Dr. Lodge's experiments, it seemed to have. It was an exceedingly difficult thing to decide between iron and copper. He did not know whether Mr. Preece had any actual experimental evidence of the superiority of copper. Iron had one great advantage—it takes a great deal more heat to melt it. Take iron at a given price, and compare the cost of iron and copper; they could get four or five times as great a mass of iron as of copper for the same money. Take also the higher melting point of iron, and they would see that for the same expenditure upon the lightning conductor they would provide for the consumption of a great deal more energy within itself without destroying it by using iron than by using copper. Then the question of self-induction bearing on magnetization must be considered before they could say for certain that in all circumstances the iron lightning conductor is as safe as copper. One conclusion seems quite sure, viz., that a sheet iron house, a sheet iron roof, with sheet iron walls and sheet iron floor, is the very safest place that we can possibly be in, or that gunpowder can possibly be in, during a thunderstorm. Here he might say something which perhaps was absolutely wrong, but he would hazard it. The subject was full of pitfalls; but he would venture to say that the magnetizability of the iron seemed in this case rather to prevent the danger—to prevent the current coming into the inside rather than to facilitate its coming into the inside. He thought he might safely say this, that within an iron funnel—an iron vertical funnel, say—and within a copper vertical funnel, the interior would be protected in the case of the iron funnel by the magnetic susceptibility of the iron; whereas, in the interior of the copper funnel, there would be no protection from this cause, although in each case there would be a very potent protection from the conductivity of the metal. However, he thought, with what Professor Lodge had put before them, they knew quite enough about iron to say that an iron building would be as safe as safe could be—as safe as science can make it. He thought that was rather an important thing for powder magazines, and the rule should be to have no special lightning conductors at all; but iron roof, iron walls, iron floor—wooden boards over the floor naturally to prevent people setting fire to the gunpowder by walking over sheet iron—and a complete roofing of iron. This iron magazine might be placed on a dry granite rock, or it may be placed on wet ground; it may be placed on anything they pleased, it might be placed on a foundation under water; no matter what the surroundings are, the interior will be safe. He thought that was a somewhat important practical conclusion which might safely be drawn from consideration of these electrical oscillations and the experiments regarding them, and the trials for the mathematical theory of them—mathematical calculations of which they had heard so much.

Professor Rowland said that he was inclined to think that the arrangement of conductors in Professor Lodge's experiments did not fairly represent the circuit in the case of a lightning discharge. In Professor Lodge's experiments the whole of the circuit between the condensers was of iron and copper, whereas in the case of lightning the greater portion was of air, and this might materially alter the condition of things. Moreover, he was not disposed to say the spark would take place at the first moment. There might be considerable oscillation, and finally the air might be broken down. The oscillation might take place before the spark occurs, in which case the length of the spark might not be an index altogether of what they might call a temporary resistance of the conductor to the passage of the spark. The presence of iron might change the time of oscillation in the same way, so that it might give a different length of spark in that case from what it did in the copper. But he thought the fact should be remembered that in the case of lightning the greater proportion of the spark was in the air, which was a very bad conductor, and that therefore the passage of the lightning might not be oscillatory, but might be of the nature of a swing, in which case a solid conductor or a conductor of copper would probably be better than a tube of iron.

M. de Fonvielle said that, though a Frenchman, he took the liberty to disagree with Sir William Thomson, and to stand with Mr. Preece as an English conservative with regard to lightning conductors. He should advise the meeting to postpone its opinion until the completion of the Eiffel Tower in Paris—the most extraordinary lightning conductor ever constructed. Paris, he must say, was remarkably free from calamities from lightning. They had erected a sufficient number of lightning rods on the principles laid down by Mr. Preece to show that he must be going in the right direction.

Professor Forbes pointed out that the great question which had to be settled was between the lightning rod committee's recommendation of copper for the construction of conductors and Professor Lodge's assertion that their views were erroneous, and that if iron were not better for the purpose than was copper, it was certainly no worse. No one could fail to be impressed by the beauty and value of Dr. Lodge's experiments; yet he agreed with Professor Rowland in thinking that they were not quite conclusive on the point in question. The reason why he thought that they were not able fully to accept Dr. Lodge's experiments on the alternative path as sufficing to abolish copper rods for lightning conductors was this: In the experiment Professor Lodge had used two condensers, and he used a special case in which there were two sparks produced beside the alternative path. He had doubtless tried the experiment in a much simpler way, and more resembling the conditions which existed in the actual phenomenon. Supposing, instead of using those two condensers, they used the two poles of the Holtz machine; or; instead of having two pairs of knobs, suppose they used only one pair of knobs. They might connect the poles of the Holtz machine with a large battery of Leyden jars, and they would get all the better effect. The arrangement then was that they got a spark between the two knobs of the Holtz machine. They put an alternative path in the course of the spark, and then they tested to see at what distance a spark was just possible to take place. He wanted to ask Professor Lodge, when that experiment was being performed, whether an iron alternative path or a copper alternative path was best. The circumstances seemed to him to more resemble the circumstances in nature than the arrangement which he had described in his experiment, and he thought the conclusion was that the copper alternative path was the best, which would be an argument in favor of Mr. Preece's view.

Sir James Douglass said that his experience, extending over forty years, might be considered comforting to the committee. They had been following Faraday's advice entirely for the past fifty years for the protection of lighthouses, starting with the base of the metallic lantern and carrying down a copper bar (1¼in. by ⅜in., half round, in section) which was in communication with all interior metal work. The earth was obtained by a copper plate, 2ft. 6in. square and ¼in. thick, buried 15ft. distant from the tower, about 12 feet below the surface of the ground. At exposed stations at sea the bar was carried down to about 8ft. or 10ft. below low water mark, so as always to be immersed in the waves. During the forty years of his experience seven or eight accidents had occurred—none of a serious nature—and in all cases they had found a defect in the conductor. He thought that the rapidity with which iron conductors corrode would present a practical difficulty to their use in many situations, particularly in hot climates.

Mr. G. J. Symons, F.R.S., secretary to the Lightning Rod Committee, said that he had had nothing to do with the construction of lightning conductors, but that it had been his hobby all his life to inquire into any accidents from lightning of which he heard. The impression left upon his mind by these investigations agreed very well with what Sir James Douglass had said. He had no shadow of hesitation in saying that he believed that if people would put up conductors precisely according to the rules, and would fulfill all the conditions, they were absolutely safe. Professor Lodge's experiments (and he yielded to none in his appreciation of Professor Lodge as an experimenter) were only laboratory experiments. What they wanted was something on a far larger scale. He thought that a good deal of information might be gained from experimental conductors erected on some high hill. It seemed to him that a very serious responsibility attached to those who would allow it to go forth from that great association, that there was any uncertainty in the protection of the public buildings of the country. They had the experience of France, Germany, Austria, and the United States, as well as of England.

Tens of thousands of rods were erected in these countries, and it would be with considerable regret that he would hear it go forth from that room, simply on the strength of some laboratory experiments, that all that had been done was to be regarded as worse than useless. He agreed with Sir James Douglass with regard to the oxidation of iron rods. Even galvanized iron was not an everlasting material by any means. With respect to the area of protection, he knew that he was within the mark when he said that hundreds of cases had been investigated, and that there were not, as regards the area of protection laid down by the conference, more than two instances in which anything had been struck within this area, and even these cases were a little doubtful. Churches were continually being struck; but then they had not properly constructed conductors. The conference had advised that the conductor should end in a blunt point, and about six inches below this there was to be a ring carrying sharp needle points—the latter to disperse the electricity and act as a preventive, the former to receive the flash if it did occur.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Meetings of the Board of Electrical Control.—Developments of Rapid Transit Schemes.—New Suburban Electric Road.—The New York Central Tunnel to be Lighted by Incandescent Lamps.—The "Times" upon the Fourth Avenue Storage Battery Cars.—Penitentiary Wardens Instructed in the Use of Electric Apparatus for Execution of Criminals.—Theatres Adopting the Alternate Current for Lighting.—The Use of Electric Appliances on Naval Vessels.—Startling Explosion of Gas in Subway Man-holes at Madison Square.

THE meeting of the Board of Electrical Control, held on March 5th, was enlivened by the presentation of charges by Commissioner Gibbens against the United States Illuminating Co. on the ground that that company was not acting in good faith. A spirited war of words ensued between the commissioner and Mr. Eugene T. Lynch, president of the Illuminating company. The company succeeded in securing forty-five days in which to test the subways, "at the end of which time," the Mayor remarked, "that if the poles are not removed I will order them taken down by the Bureau of Encumbrances."

The Mayor thought he detected a scheme to prevent the removal of poles of the Western Union Co., the police department having wires strung upon that company's poles, and measures were taken to secure an appropriation to put the city's wires in the subways, and at a subsequent meeting the board was informed that $15,000 had been set aside for that purpose.

At the meeting of the Board of Electrical Control, held on March 19th, the Mayor stated that it was useless to read the long list of applications to string wires, as under no circumstances would they be granted. As a consequence of such repeated refusal to consider such applications a large number of enterprises are at a standstill. The board ordered the construction of subways as follows:—

West side of Sixth ave., from Fourteenth to Eighteenth sts., and east side from Fourteenth to Twenty-fourth sts; south side of Fourteenth st., from First to Sixth aves.; Twenty-ninth st., from First to Fifth aves.: Murray st., from Broadway to College place; Centre st., from Worth to Grand st.; Houston st., from Crosby st. to First ave.; Thirty-eighth st., from First to Lexington aves.; Seventy-ninth st., from First to Park aves., and Lexington ave., from Sixty-fifth to Seventy-ninth sts.

The efforts being made to secure rapid transit have naturally been opposed by the stockholders of the elevated railroads, who seem to have counted upon ultimately securing additional privileges. Mr. Jay Gould, president of the Manhattan Elevated Railway Co., writes to Mayor Grant under date of March 7th, offering this solution of the problem:—

"Let this company build a third track on Third and Ninth avenues and increase the terminal facilities at Battery place and Brooklyn Bridge." Such concessions would be violently opposed, as only affording a temporary makeshift and injuring property more than ever. It is believed that Mayor Grant's plan is to purchase a strip of ground on the east side in the centre of the blocks and erect a stone structure wide enough for four tracks from Battery place to the Harlem River.

The Port Chester, White Plains and Tarrytown Railway Co. will be run by electric motors and the overhead system. This line will run through a thickly populated residence district, and may ultimately be extended farther up the river.

The Fourth avenue tunnel of the New York Central Railroad, which has been described as an "ugly, smoky, dark and disagreeable cavern," is to be lighted by incandescent lights.

"The New York *Times*, in a recent editorial referring to the Fourth avenue storage battery cars, says:—"The electric motor cars, now run for a short time in the evening, are a revelation to New Yorkers of what comfort, and even luxury, is possible in a mode of travel that has heretofore been a continual nuisance."

The legislature having made the necessary appropriation for the execution of criminals by electricity, the wardens of the three state prisons have been receiving instructions from Mr. Harold P. Brown at Menlo Park, N. J.

The first theatre in this city to install the alternating current is Proctor's new theatre on Twenty-third street. The installation was made by the Manhattan Electric Light Co., which operates the Slattery induction system. The system has given such satisfaction that it is said three other theatres contemplate adopting it.

A naval officer during the trial of the new steamer "Vesuvius" remarked "that the countless devices by which electricity is made applicable aboard ship are simply marvelous. Small electric motors are used about the decks and below for hoisting and other purposes, and all parts of the ship are brilliantly lighted without the usual attendant heat and exposed flame. The difference in ventilation alone calls for unceasing praise. Search lights are now provided of sufficient power to light up the water a radius of nearly a mile, and so detecting the approach of any object." The "Chicago" is fitted with a complete duplicate plant, and it is expected that all new steamers will be fitted out with duplicate electrical apparatus.

Three explosions in the subways occurred almost simultaneously just before noon on March 25th, and within 200 feet of the entrance of the Fifth Avenue Hotel at Madison square. The people in the streets and square were thoroughly frightened. and many narrow escapes from flying cobblestones were reported, but no serious injuries were done, excepting, possibly, to one lady who was struck on the knee by a cobblestone and was taken home in a carriage in a fainting condition.

The Board of Electrical Control immediately issued the following announcement:—

The explosion was the result of the leakage into the subways of quantities of gas from the mains of companies operating in the neighborhood. It was not directly or indirectly brought about by any underground electrical current, inasmuch as no electrical current was passing through the subways at the time of the explosion. It would have occurred in a closed cellar or any other receptacle into which like kinds of gas could penetrate and combine with air and other gases under similar circumstances. The man-holes at which the explosion took place are frequently examined and ventilated. There are five gas companies operating near by, and it is impossible to tell as yet which one or more should be held responsible for the leak or leaks occasioning the explosion. The following letter has been sent by order of the Board of Electrical Control to each of the gas companies:—

"Your attention is called to the fact that, owing to a leak or leaks from gas pipes in the vicinity, three of the subway man-holes at Fifth avenue and Twenty-third street were exploded this morning, causing serious inconvenience and seriously endangering lives of citizens.

"Your company has mains and connections in this neighborhood, as well as elsewhere in the city. You are respectfully requested to take immediate steps to prevent any further escape of gas into electrical subways, if such escape comes from your pipes in this or any other locality."

Inasmuch as no loss of life has resulted from this explosion, it is, perhaps, fortunate that it occurred before the electric current had been transmitted over the wires placed in the subways, for if any of the conductors in the subways at the time of the explosion had been in operation, a new and serious question as to the practicability of operating electrical conductors underground would immediately have been raised.

The Board of Electrical Control will take measures to exclude all kinds of gases from the subways in the future as in the past with even more vigilance than hitherto; but the exclusion of the gas from the subways has the effect of driving it into the basements of buildings, and the real remedy is in the hands of the gas companies, inasmuch as upon them the responsibility of keeping gas within its proper channels and the prevention of casualties and illnesses caused by its escape must ultimately rest.

NEW YORK, March 22, 1889.

PHILADELPHIA.

The Philadelphia Electric Trust a Profitable Venture.—New Electric Light Companies Projected.—A Bill to Abolish all Overhead Wires in Cities before September next Introduced in the State Senate; Comments Upon It.—The Bell Telephone Company of Philadelphia; its New Building and its Subway Work.—Electric Light Service at Pottstown, Pa.

THOSE gentlemen who hold the preferred stock of the Philadelphia Electrical Trust are said to have made a pretty good thing out of it. There are 5,000 shares of a par value of $100 each, and they are now quoted at about $145. They are guaranteed 8 per cent. The common stock, which amounts to $3,000,000, is quoted at from 33 to 35, and earns about two per cent. The Electric Trust has a controlling interest in all the local arc light companies, and carefully sees that no one encroaches on another's territory. Thomas Dolan, the president of the trust; John Lowber Welsh, R. H. C. Hill, William G. Warden, George I. McKelway and William Wood are some of the gentlemen who are credited with having added to their incomes by their investments in the trust.

There is a movement on foot among South street business men to run an independent electric light plant, and boycott the companies who now furnish the lighting in that region. Already the movement has taken an organized form under the name of the "South Street Merchants' Association," with the following officers: President, W. H. Embick; secretary, Joseph Gregson; treasurer, James Gallagher, and directors, Andrew Marshall, Joseph Hollard and W. H. Carslake.

Every effort is being made to keep the project a secret until the plans are perfected and the association in shape to meet the opposition the members expect to meet from the electric light companies, to whom it will prove a dangerous rival, owing to the cutting in rates which is proposed. The association will be a stock company, and to those holding stock lights will be furnished at 20 cents per night, and to the outside public at 40 cents, the last price being a large reduction from the terms of present companies. Further, to secure the sanction of the city councils in the scheme, it is proposed to place a light in the centre of each square for a considerable distance down Gray's Ferry road, for which the city will be charged nothing.

The merchants of the northeastern section of the city also have the electric light fever, and an ordinance granting permission to the Merchants' Electric Light Co. to open streets, and lay and maintain underground conduits and wires for electric lighting was considered at a meeting of the electrical committee in select council chamber recently. The ordinance authorizes the company to lay its conduits and maintain its wires under a number of streets in the northeastern section of the city, and contains the proviso that no street be broken until the plans of the company shall have been approved by the board of highway supervisors. The ordinance was directed to be reported to councils with a favorable recommendation.

In the Senate at Harrisburg, on February 28th, Mr. Harlan presented a bill prohibiting all suspended electric wires in cities of over 30,000 population after August, 1889.

"It is a physical impossibility," said Chief Walker, of the electrical bureau, when asked his opinion of Senator Harlan's bill for putting electric wires underground. "Why it would take five years to carry out the provisions of the bill," said he. "Every one knows that I am a strong advocate of underground wires, but it will take time, and no man who lived in a large city would propose a bill of that kind. There are 12,000 miles of overhead wires strung within the city limits, There are already 600 miles of wires underground and more being placed. But to talk of burying 12,000 miles of wire in six months is absurd, and it will cost $5,000,000 to do it, too.

"The tendency of electricians is to put all wires underground, and the best interests of the city demand it. The removal of danger to life is, of course, the first consideration, and the danger of spreading fires would be greatly lessened if every overhead wire was buried out of sight. There's nothing scares a fireman like a live wire hanging over his head. Among the electric light companies the incandescent concerns are all willing to bury their wires; but some of the arc light companies say that the underground system is in its infancy, and not far enough advanced for their purpose."

Dr. Plush, general manager of the Bell Telephone Company, said that his company was placing wires underground as fast as possible, but that Senator Harlan's bill was impracticable, inasmuch as the laying of conduits alone for all their wires would occupy at least a year.

The Bell Telephone Company, of Philadelphia, has awarded the contract for the erection of a headquarters and central office building at Nos. 406 and 408 Market street. The new building will be handsome, and in keeping with the many massive structures that have been built in the business section during the past few years. The company will spend $75,000 for a switch-board in the new building.

In a few weeks the telephone company will continue work on the subway on Market street, which is designed to hold all the wires that are now overhead on that and adjacent streets. The subway extends from Front to Eleventh street, and will be continued out Market street to the Schuylkill river. It will make a detour around the City Hall via Thirteenth, Arch and Fifteenth streets. Most of the work will probably be completed within the present year. The plan is to have small conduits extending from Market street on every alternate street, so that wires may be carried through them to a tall pole in the centre of a block and then distributed to the buildings within the block. This work is designed to bury all the wires between the two rivers and Vine and South streets, and will entail a cost of $1,000,000. The Western Union Company's wires will also be carried in the same subway and conduits.

The borough council at Pottstown, Pa., have agreed to accept the electric light service now offered at $125 per arc light per year. The lights are of nominal 2,000 candle-power, and are to burn all night.

PHILADELPHIA, March 18, 1889.

.... WE must not forget that the province of the electrical engineer touches upon that of the civil engineer.—*Sir William Thomson,*

.... IN no other way can a city promote industry among its citizens as surely as it can by securing for the largest possible number the use of light and power, under conditions favorable to their requirements.—*A. R. Foote.*

BOSTON.

Activity in Electrical Affairs.—Output of Telephones.—Favorable News Advance the Price of Bell Stock.—Connecticut Legislates Against Eavesdropping by Telephone.—Annual Statement of the Central and South American Telegraph Company.—Boston Aldermen Take Up Electric Lighting.—An Exhibition of Electrical Welding.—High Prices for Thomson-Houston Shares.—Overhead and Underground Wires—The Hearing at the State House on Street Railway Conductors.

THE electrical pot continues to boil in this vicinity; the introduction of electric railways and the transmission of electricity for motive power of all kinds stirs up things wonderfully. The telephone people complain that the strong currents interfere with their service. Last month the telephone company cut the wires of the Woburn Electric Light Company, between Fowle street and Winchester. The companies have disagreed for some time regarding their respective rights, and the electric light company placed wires on the poles after being requested not to do so.

The statement of the output of telephones by the American Bell Company for the month ended Feb. 20 is as follows:—

	1889.	1888.	
February—			
Gross	4,231	3,972	Inc. 259
Returned	2.212	2,088	Inc. 124
Net	2,019	1,884	Inc. 135
Dec. 21 to Feb. 20.			
Gross	8,078	8,002	Inc. 76
Returned	4,129	3,760	Inc. 369
Net	3,949	4,242	Dec. 293

The repeal of the "Indiana law" last month helped to send the American Bell stock up to 229; of course the recent legal victories contributed to send the stock up, as did also the report that the long-delayed microphone patent was soon to be issued to Berliner.

A bill was passed by the Connecticut Senate the first of this month, aimed at a new class of "Peeping Toms." In the Trowbridge-Ingersoll scandal case in New Haven, some months ago, important evidence was obtained by tapping a telephone wire and listening to conversations between the lady and her admirer. While this was indirectly in the interest of detecting wrong-doing, the telephone company was indignant, and asked for the bill which passed. It imposes a fine not to exceed $500 on any person who shall make a connection by wire or otherwise with any telegraph or telephone wire, not owned or leased to such person, for the purpose of obtaining information or listening to the transmission of messages.

The annual statement of the Central and South American Telegraph Company for the year ending Dec. 31, 1888, shows: Gross revenue, $538,729; operating expenses and expenditures for ordinary repairs, $133,261; dividends on $4,006,600 capital stock, $270,445; surplus, $135,022; total surplus Dec. 31, 1888, $331,596, including $201,001, the surplus of previous years. The time required to transmit messages between Buenos Ayres and London, "via Galveston," is now less than forty minutes. The report says that a duplicate cable between Galveston, Texas, and Coatzacoalcos, Mexico, was completed on Feb. 19, and that its cost will be provided for out of the surplus earnings of the company.

The committee of the board of aldermen have returned from a trip to Chicago, to inspect the underground wire system. They went at the invitation of the Boston Electric Company, who paid their expenses. On the 4th, as a result of their trip, the aldermen passed the following order:

That the committee on public buildings consider and report as to the desirability of placing in the basement of the City Hall an electric light plant of sufficient capacity to light the entire City Hall, Court House and the building occupied by the Register of Deeds.

In response to an invitation from the Thomson Electric Welding Company, a large party assembled at the station of the Malden Electric Works, on the evening of the 4th inst., to witness the process of welding by electricity. Among those present were representatives of the Boston and local press, members of the Malden City government, and gentlemen actively interested in the development of electrical industries. The full capacity of the apparatus was shown by the union of two pieces of iron two inches in diameter, the time required being a little more than a minute. The power employed is directly proportionate to the size of the pieces to be welded, and, by increasing the horse-power, much heavier work is possible. The variety of uses to which this method of welding may be applied is almost endless, and it is destined in the near future to be of the greatest value to the metal interests of the country. On the evening of the 7th inst. another exhibition was given.

The Thomson-Houston stocks have appreciated rapidly within a few weeks. This week Thomson-Houston Electric Company's shares were quoted at 275 bid, 300 asked; Electric Welding at 400.

At the State House hearings, overhead wires and electric street railways are having a shaking up.

The hearings in regard to the dangers from overhead electric wires on street railways have been very interesting. It is signifi-

cant that the opposition to the overhead method comes from gentlemen interested in the storage system. But when men come forward and tell of taking the strongest alternating current, without serious result, the fears of the people of dangers from the comparatively feeble currents employed by the street railways are quieted to a considerable extent.

In the mass of testimony submitted it is very hard to extract or boil down. But some very interesting statements have been made; none more so than the communication of Mr. F. L. Pope.

In regard to the physiological effects of high potential currents Professor Elihu Thomson said that the amount of current which a man is capable of receiving depends upon his power of resistance. In Lynn, his company is welding iron bars with a current of 50,000 amperes, but you can put your tongue between the ends of the wires and not feel the current.

The destruction of human life, he said, usually came from a wire of 2,500 or 3,000 volts; it was the opinion of electricians generally that the danger point is above 1,000 volts.

William McQuesten, in charge of the West End electric railway system, said he had taken two shocks, in one case the voltage being 1,200. He never knew of destruction to human life from the overhead wire. He said that the West End's wires were protected by fusible joints. It was only an instant, just as the wire fell, that a shock was possible. In regard to other wires falling on the road's wires, he said the latter were protected by guard wires, which made the falling of telephone or telegraph wires across the road's wires next to impossible. Further testimony was submitted by men who had received shocks to show that the wires are not fatally dangerous.

Mayor Russell appeared for the Cambridge Electric Light Company, and several of the officers and employés of the company testified. One of the employés had taken a shock from a 500-light alternating current dynamo of 1,000 volts.

Mr. C. J. H. Woodbury, of the Massachusetts Mutual Factory Insurance Company, was called by Mr. Cummings, and testified that no higher rates were demanded for factories in which electric lights are used.

Mayor Russell, of Cambridge, spoke of the absence of danger in the overhead wires, and said that if the voltage of these wires is limited, the same limitation must apply to the light and power wires, and thus would a blow be struck at the immense industries which are being developed by electricity.

On storage batteries for street cars, at the State House hearing, Mr. S. A. B. Abbott presented numerous affidavits as to the practicability of the Julien storage system, and Mr. Wm. Bracken testified to the same effect. He said that Mr. Whitney would have adopted the system on the West End Railway but for the fact that the storage company declined to agree to light the cars. Mr. Abbott said that he had shown that all the dangers incident to the overhead system might be obviated by the storage system, and he claimed that it could be obviated also by the conduit system. At all events, it was due to the public that all other methods should be properly tested before resorting to the overhead system. There should be a limitation of the voltage to 500 volts, and a provision that there shall be a registry of the voltage kept. He asked further that the use of the alternating current be prohibited.

Mr. Hyde said that the only opposition to the overhead wires came from a storage battery company of New York, which had a system that no railway company was willing to adopt, and the storage company has the assurance to come here and ask the State of Massachusetts to legislate in its behalf. The West End Railway Company had spent $15,000 in experiments on the storage system, and it was not a success; when it was demonstrated to be practicable and efficient, he should be glad to adopt it. The West End company were forced to resort to the overhead system, and no accident had occurred on the road. It was the most efficient, economic and best adapted for street railway cars that has been found thus far. He could not say what progress might not be made in the future. He had no objection in having a clause in the bill permitting the use of the storage system. Give all a chance, he said, but let us have none of their dog-in-the-manger policy.

Mr. Bracken, of the Julien company, then went on to speak of the advantages of the storage system. He was subsequently questioned by Mr. Hyde, his answers bringing out the facts that it required six or seven hours to charge a battery; that the batteries in a car weighed 3,400 pounds; that they contained sufficient energy to last six hours, and that it costs two cents per car mile to run cars in New York. To the committee Mr. Bracken said that the company had sold none of its cars, but was now ready to do so.

As to conduits, Mr. Bracken submitted documentary evidence in support of his proposition that both alternating and continuous currents are dangerous to life when carried overhead. In regard to the alleged failure of the conduit in Boston, Mr. Bracken said the conduit system was doing a thousand times better than the overhead system was doing a year ago.

Professor Thomson said he understood the conduit system was not a success. He predicted that it would not be, on account of the leakage, which the peculiar conditions made it impossible to overcome. He knew of no conduit system in existence which he would trust. He would, however, gladly welcome a conduit system which was feasible. He would prefer a conduit for city work. He did not like to see the wires any more than anybody else. He was not in love with them. In out-of-town work there can be no question that the overhead system will always be the most economical as well as the most practicable. In reply to Mayor Russell, of Cambridge, Professor Thomson said that, in case of restrictive legislation compelling the wires to be placed underground, the whole enterprise would be defeated and the use of electricity abandoned. The difference in the cost of the two systems must be considerable. The overhead line can be put in for $2,000 or $3,000 a mile; it was impossible to say how much the conduit system would cost, but it would be many thousands, and probably so high as to be prohibitive.

BOSTON, March 16, 1889.

CHICAGO.

The Chicago Electric Club; Dr. De Bausset on Aerial Navigation; Mr. Cutter on Handling Electric Light Circuits: Interesting Experiments.—Professor Barrett on Electric Subways.—Electric Train Lighting on the Atchison, Topeka & Santa Fe R. R.—The Chicago Medico-Legal Society Discusses Electrical Execution.—Electric Motors Suggested for Drawbridges on the Chicago River.—Marriage of Mr. John H. Reed, of the Mather Electric Co.—Electric Light Employees Nearly Killed by Suffocation in a Conduit Manhole.—The Leonard & Izard Co. Organized to Succeed the Firm of Leonard & Izard.

AT the meeting of the Chicago Electric Club, March 4th, Dr. A. De Bausset spoke on the subject of aerial navigation. He described in detail the air ship which he proposes to build whenever he obtains financial encouragement from the government. His plan is as has been stated a number of times, is to exhaust the air from a cigar-shaped steel cylinder 600 feet long and 120 feet wide. According to his calculation enough air will be displaced so that his ship will float in the atmosphere. A car will be attached to the cylinder in which machinery, 200 passengers and 50 tons of freight will be carried. He proposes to use a wheel similar to a propeller wheel and to employ storage batteries and a gas engine for motive power. Dr. De Bausset is confident that his scheme is practicable. He has figured out every detail so that he can state the exact material of which each portion of his cylinder and car will be composed. He believes that Congress will soon give him money enough to make the first ship, the cost of which will be about $150,000.

At the Club meeting, March 18, George Cutter gave a practical talk on suggestions for handling electric light circuits. A large number of members was present. The subject was treated by Mr. Cutter in a popular way, and was illustrated by several experiments of an interesting character. Mr. Cutter showed the heating effects of the electric current; its effect upon the magnetic needle, the effect of the magnet on the voltaic arc were among the experiments.

Professor J. P. Barrett, city electrician of Chicago, is a firm believer in the underground system, as he indicated during the convention of the National Electric Light Association. He said recently, "The subway commission in New York seems thoroughly in earnest and I am not surprised, for the conduits which have been constructed in the city seem to be models. The people demand the burial of wires and it will have to come to that. The underground system in Chicago has been successful and it will also prove economical."

The Atchison, Topeka & Santa Fe Railroad Co. proposes to extend its system of electric lighting to all its trains running out of Chicago. Heretofore only vestibuled trains running to Kansas City have been equipped with electric light apparatus. On the local trains only storage batteries will be used. The coaches will be run into the yard and the batteries charged without removing a cell from its position under the car. The through trains will continue to be equipped as at present, with Brotherhood engine and storage batteries.

The Chicago Medico-Legal Society has been discussing the question of electric executions. The New York plan did not meet with the approval of the physicians. To put it bluntly, they considered that hanging was humane enough for the criminals who were punished for capital crimes. One doctor stated his preference for poisoning the criminal, in accordance with the Grecian custom.

The Chicago *Herald* has been urging the employment of electric motors for operating the drawbridges in Chicago. In an editorial on this subject it says:—

> With steam, the weight of the structure is very largely increased by the boilers and water, as well as other cumbersome appliances. There must now be a steam engine and boiler for each bridge. In case electricity were used it could be generated at some central point and carried by wires to the various bridges. The bridges could, with only the additional weight of an electric motor, be made much lighter than they are at present. This would be a substantial economy in the cost of construction, which would lighten materially the expense of bridge building. In truth, the time is not far distant when the electric motor will be an economical substitute for the great majority of engines now operated by steam

John H. Reed, manager of the Chicago office of the Mather Electric Co., and Miss Lillian A. Smith, of New York, were married March 3, in Chicago.

Two employés of the Chicago Arc Light & Power Co., had a narrow escape from suffocation by gas in a man-hole recently. They were rescued by a policeman.

The Leonard & Izard Co., of Chicago, has been formed to assume the business heretofore conducted by the firm of Leonard & Izard. The object of the corporation is stated to be "to deal in engines, electrical appliances and supplies of all kinds, to build electric railways and to furnish experts in electrical engineering work." The incorporators are H. Ward Leonard, E. M. Izard and H. K. Tenney.

CHICAGO, March 21, 1889.

MONTREAL.

The Annulment of the Edison Incandescent Electric Lamp Patent.—Complicated Relations of Telegraph Companies.—Business of the Royal Electric Co.—Electric Lighting Notes.—The Underground Wire Question Arising in Canada.

READERS of THE ELECTRICAL ENGINEER will have seen the announcement of the annulment of the Edison lamp patent in Canada, through a decision of the Commissioners of Patents at Ottawa. The effect of this decision will be far reaching respecting electric lighting in Canada, the commissioner's decision giving a color of doubt as to the value of many patents held in Canada.

Early in the year 1888, the Edison company brought suit in the Superior Court, at Montreal, against the Royal Electric Co., for infringement of Edison patent No. 10,654, usually known as the "Edison carbon filament patent." This patent was considered a controlling one. The Royal company in defense brought a counter suit before the Commissioner of Patents praying for the annulling of the Edison patent.

The Commissioner in his decision[1] discusses the case fully on the merits and in its relation to precedents. The judgment has attracted widespread public notice, not only in the Dominion but in the United States, where its effect upon the Edison patent for the same invention will, it is thought, be disastrous to the Edison interests.

That public sentiment is awake to the need of a reform in the patents' act, giving a more liberal scope to Canadian patents, will be seen by the following from a contemporary:

> We do not desire, at present, to criticise the judgment of Mr. Pope in the Edison case, but we cannot refrain from expressing our opinion that the time has now come when a change should be effected in the Patent Law with respect to the Patent Office decisions. It does not appear to be reasonable that in matters of such grave importance as these patent cases usually are, one judge—however able—should be the final arbiter of great and valuable interests. An appeal should certainly be allowed to the Supreme Court of Canada. Without wishing to be understood as expressing the slightest doubt as to the impartiality or ability of the present occupant of the position, it does undoubtedly shock one's sense of justice that the determination of questions of intricacy and magnitude should be left to the irrevocable and final judgment of any single judicial officer. The interests of patentees should be as carefully guarded as any other class, and we venture to suggest to the government the amendment of the patent act in the direction indicated.

There has been a telegraph squabble on the tapis for some time, resulting from the lease of the Montreal Telegraph Co. by the Great Northwest Co. an ally of the Western Union.

About 1880, there were only the Montreal Telegraph Co. and Canada Mutual Telegraph Co. operating in Canada; the latter, the Western Union connection. Both companies were running at a loss. The Western Union Co., acquired the charter of a company termed the Great Northwest Telegraph Co., and began active preparations for a competitive system as against the Montreal Telegraph Co. Advances were about this time made to the Montreal Telegraph Co. looking toward a permanent lease of that company's property and franchises. The lease was signed in 1881, and is for a term of 99 years. The Western Union are sureties, guaranteeing the payment to the Montreal Telegraph Co. a dividend of eight per cent. during the continuance of the lease. There is a proviso allowing the Great Northwest Telegraph Co. to release themselves by a lapse of 30 days in the monthly payments. This they are unwilling to do as heavy investments have been made by them in construction and extensions. They have accordingly proposed to the stockholders of the Montreal Telegraph stock to reduce the dividend to six per cent., with a covert threat to allow the lease to lapse. This not having the desired effect, they now sue the Montreal Telegraph Co. for breach of contract in not maintaining rights of way ceded to the Great Northwest Co. over various lines of railroad, throughout the Dominion. The Canadian Pacific Railroad Co. during 1882 and the years subsequent, leased the above-mentioned roads acquiring the right therewith to erect telegraph lines on the right-of-way thus obtained, and commenced a competitive business on what should be the right-of-way of the Great Northwest Co.

Now comes the rumor on the streets, that the Canadian Pacific have expressed a willingness to amalgamate their telegraph system with that of the Great Northwest Co. If such should become the case at a later day, the telegraph field here will then be entirely in the hands of the Western Union's ally, the Great Northwest.

The Royal Electric Co. are very much pushed in their factory, and are running up to eleven o'clock at night.

1. An abstract of the decision is printed in our Legal Notes.

They have recently wired the Standard building for 150 lamps and the Bank of British North America for 25 lamps. The Cyclorama is being supplied with 17 arcs. The Craig people have placed a 300-light series system station at St. Jerome, and are lighting that village. The electric light situation in Toronto has resulted in a petition to the Ontario government and to the Dominion government praying for power to enable the Ontario government to make it compulsory that all electric wires throughout that province shall be placed underground. This bill comes up in the Dominion parliament to-morrow. Such a bill would seriously cripple the electrical industries in Ontario, and it is believed no such bill will pass. Meantime, the electric light companies at Toronto are awaiting the issue of this bill, until the city council can enable them to proceed either overhead or underground. The Toronto council appointed a committee who recently visited the states to inspect underground work there with a view to placing wires underground in Toronto. As yet nothing has been done.

MONTREAL, March 19, 1889.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall street, New York city.*

THE BATE CASE—ARE YOU RIGHT?

[104.]—It is usually pretty safe to be, in matters concerning patents, on the same side of the fence with the editorial articles of the ELECTRICAL ENGINEER.

A close observation of the decision in the Bate case recently, does not, however, in the humble opinion of the writer warrant the doctrine editorially stated in the March number, "that foreign patents terminating prematurely, by the failure of the patentee to pay taxes or stamp duties, will adversely affect a previously issued United States patent for the same thing."

No tribunal in the world is so careful to abstain from crossing a bridge before reaching it as is the United States Supreme Court. This court even in the Bate case declined to express an opinion upon a point, which though argued, was not properly in the case.

It hardly seems fair, therefore, to read into the Bate decision an opinion upon a point which did not even remotely enter into the case.

The untimely expiration of a foreign patent issued for a full term, because of the non-payment of a periodical tax is, so it seems to me, on quite a different footing from the expiration of a short term patent which might have been but was not renewed. When a patent is applied for in foreign countries, it is usually under the control of the patentee, and he may elect for himself (if he first takes out his foreign patent), whether he will take one for a long or short term; that is, of course, in countries where this can be done. But generally the patent once issued passes to an assignee, who may, if he finds it unprofitable, let it fall by the non-payment of a periodical tax. It would, to say the least, appear inequitable, if a patentee in the United States should be made to suffer for the action of a licensee. Moreover, the action of the Supreme Court is in the line of aiding the patentee, and such a construction as was placed upon its decision by the ELECTRICAL ENGINEER would be adverse clearly to the spirit embodied in the said decision.

OBSERVER.

LITERATURE.

The Telephone. BY WILLIAM HENRY PREECE, F. R. S. and JULIUS MAIER, PH. D. London: Whittaker & Co. New York: D. Van Nostrand, 1889. Crown 8vo., cloth, pp. xvi. 498. Price, $4.00.

THIS new volume of The Specialists' Series is a praiseworthy attempt to meet a long felt want in the literature of telephony, and is evidently the product of no small amount of conscientious labor. The plan is comprehensive and in general satisfactory; but we regret to find errors of a sort hardly to be expected in a work for which Mr. Preece assumes the chief responsibility. It is, in fact, mostly compiled from other books and from electrical journals, and should at least have been revised by some one practically familiar with the subject. The title is ambitious, but the book does not fully supply the need of a hand-book of telephony.

The preface states that little heed has been paid to priority, but this disclaimer is hardly a sufficient excuse for describing the ordinary American Bell telephone as "the Bell Receiver of the

Swiss Telephone Administration." The statement that "by continuous improvements and careful workmanship this instrument is said to have been brought to a state of perfection which is not surpassed by any other Bell receiver now in use," is not a little amusing, in view of the fact that the description is that of the Bell hand telephone exactly as made in America and put on the market about 10 years ago.

One of the older forms of the well-known standard switchboard appears under the guise of the "Swiss Commutator," while the present form of the same instrument is credited to Mr. Charles Williams, Jr., instead of to the Western Electric Co., from whom the Swiss appear to have got their first model about eight years ago—if we may judge from the pattern illustrated.

Curiously enough, too, the description of the standard switchboard is jumbled up with that of the Williams' plug switch.

The ordinary American pole-changer is also shown as a part of the "Swiss System," but is not called by its accepted name.

The form of Edison transmitter shown and described is not the one which was adopted in practice, but an earlier model, of which very few were made.

Under receivers and transmitters a number of unimportant and rather rubbishy instruments are shown which have scarcely ever been seen outside of electrical journals, while some forms which have come into pretty wide use are entirely omitted; no mention being made, for instance, of the American "long-distance" transmitter, or of the Pony Crown telephone, or of the present receiver of the German Telegraph Administration. Nor is Hunnings (called Hunning in the book) recognized as the original inventor of the granulated carbon transmitter. He is classed along with his followers—Hipp, Berthon, Berliner, etc. We are inclined to consider the Hunnings's transmitter as perhaps the most important European contribution yet made to the development of telephony.

A series of tests of induction coils, to ascertain the most efficient form, is cited and discussed at length, without a reference to the omission of elements so essential as the size of core used, and the amount of battery power applied; omissions which render those tests almost worthless.

The treatment of the magneto is inadequate; insulators are neglected; and house-top fixtures are not even mentioned. We should have been glad to see illustrations of some of the graceful iron fixtures used in continental cities, which long ago replaced the clumsy wooden ones, such as are still so abundant in America.

The bronze line wire mentioned (0.8 mm., or 32 mils), seems to us absurdly small. We have heard of telephone companies renouncing the use of 1.25 mm. wire (50 mils), as too small, and adopting heavier wire. The discussion of air lines, however, is much more satisfactory than that of cables, which is very weak. We take leave to differ with the view that the first requisites of aerial cables are lightness and tensile strength, and the American telephone engineer, accustomed to the common use of 50 and 100 wire aerial cables, will be somewhat surprised to be told, on the authority of the technical chief of the British telegraphs, that the practical limit of the number of wires in an aerial cable is 27. What would Mr. Preece say, we wonder, to the 150 wire aerial cables at St. Louis, or the 200 wire cables at Chicago?

The statement that "underground work has hitherto been tabooed" in America, is rather wide of the mark, the fact being, of course, that American cities have five or ten times more underground telephone cable than all Europe! The question of retardation is not even mentioned. The shielding of the conductors with lead or tin-foil as a remedy for induction between wires, which is apparently recommended, does not meet with favor in this country.

The British post office occupies a good deal of space in the book, considering its rather unimportant position in telephony. The description of the "Post Office System" is the first chapter under telephone exchanges. The "system" appears to be entirely official as to its origin. The switch-board especially is truly official in its clumsiness, and we do not wonder that the P. O. subscribers—officially called "renters"—are even willing to throw themselves into the hands of that grasping monopoly, the telephone company, in their anxiety to escape from the too affectionate embrace of a paternal government. The range of the official mind may be inferred from the mention of exchanges "of from 100 to 300 subscribers" as "medium sized."

Although the book contains many errors, and is therefore unfit to place in the hands of the inexperienced, there is in it also much useful information, well arranged and agreeably presented. It is so good that it ought to be a great deal better without much difficulty, and we trust that the sins both of omission and of commission will be atoned for in a later edition; when we hope that the statistics and general information as to the state of the art may be brought down nearer the date of publication. The most satisfactory portions are, perhaps, the introductory chapters and the description of the multiple switch-board. The illustrations are atrocious, with a few exceptions, one being the frontispiece—an excellent picture, by a photographic process, of the Manchester Telephone Exchange, recently fitted with new switchboards.

We would suggest for the mutual benefit of both publisher and reader, that the book would probably have a greater success in this country if offered at a more reasonable price. The American telephonist who pays $4 for it is likely to conclude that he has paid about $2 too much—and to say so.

Notes.

R. VON FISCHER-TREUENFELD'S Index of Publications on Methods of Communication in the Field and on Torpedo Warfare, recently published by H. Alabaster, Gatehouse & Co., London, will be found useful by military readers and by students of modern methods in warfare. The index, as would be expected, deals mainly with the various military applications of electricity, but includes references to military railways, communication by carrier pigeons, carrier dogs and velocipedes; and to such topics as military ballooning, audible signaling and cryptography. More than 700 titles are given of books, pamphlets and articles in technical journals, covering English, German, French, Italian and Spanish publications. They are classified under twenty-nine headings. The principal subjects are fairly summarized by the title of the book:—Communication (telegraphy, telephony, signaling); Torpedo Warfare (explosives, exploders, torpedoes, military mining, etc.). A few topics scarcely less important, but not coming under either of the above heads, are included, such as electric lighting and light apparatus, ballistic apparatus and range finders.

WE have had on our table for some time, Three Kingdoms: A Hand-book of The Agassiz Association, written by President Ballard and issued by The Writers' Publishing Company, New York Its dedication "to the memory of Louis Agassiz, in the hope of leading many to follow in his footsteps", is well fitted to the purpose of the book, viz., to make known the organization, scope and methods of the Agassiz Association and to make its work attractive to all who have leisure or inclination to join it for the observation and study of natural objects systematically. The association's scheme should be particularly attractive to the young. Boys and girls may under its guidance acquire habits of close observation, and systematic classification of familiar or unfamiliar objects in the natural world of the utmost value; to say nothing of the great pleasure and satisfaction attending such work. It is gratifying to read that in seven years more than 15,000 students had been aided in their work and over 1,200 local societies had been formed. Three Kingdoms is a handsome little volume. It gives full information about forming local societies, plans of work for societies or individuals, and some preliminary rudimentary instruction in the study of nature. It is to be hoped that the book will fall into the hands of the many bright girls and boys who would find in it an incentive to useful and delightful work.

[Meetings from September 20, 1887 to October 9, 1888.] New York: *Published by the Institute.* 8vo., cloth, 435 pp, and appendix—Index of Current Electrical Literature—pp. xiv.; xv.; xvi.; xxi.; xxii.; xix.; xviii.; xvi.; xviii.; xiii.;

CATALOGUES AND PAMPHLETS RECEIVED.

The Automatic Switch Co., Baltimore, Md., issue a pamphlet circular describing the Whittingham Automatic Switch, and offering it to the trade. The switch is designed for use in starting and stopping constant potential motors. By a clever arrangement of lever and a dash-pot, one motion on the part of an attendant serves to put the field magnets of a motor into circuit and to set in operation the gradual admission of the current through the armature automatically. The circular contains a good description of the device handsomely illustrated.

We have received a new circular and price list from the Simplex Electrical Co., Boston, containing fresh information as to the use of their insulated wires, tapes and tree insulators. Besides the usual wire tables the circular contains many testimonials to the high quality of the simplex insulation.

We have recently received the new circular of the "Elgin" Telephone & Electrical Supply Co., Elgin, Ill. This company has been for several years engaged in manufacturing and supplying mechanical telephones, and has carried that mode of communication to a very serviceable degree of utility. They have also for some time carried on a business in general electrical supplies, telegraph instruments, batteries, house service apparatus, etc. Their list fills a 48 page pamphlet.

.... IF all the obstructions that have ever been placed in the way of any step of progress were rolled into one, and placed in the way of the advent of electric light and power, it would be impotent to very much hinder the progress of the inevitable.—*A. R. Foote.*

NEWS AND NOTES.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

February and March Meetings.

MEETING OF FEBRUARY 12th, 1889.

The meeting was held at the College of the City of New York.

In the absence of the president, Mr. C. O. Mailloux was chosen chairman for the evening.

The chairman, after appropriate introductory remarks, called upon Lieutenant F. Jarvis Patten, who then, according to the programme of the evening, read a paper on "A New System of Multiplex Telegraphy." (See ELECTRICAL ENGINEER, March, 1889, page 85.)

DISCUSSION.

The Chairman—It is rather to be regretted that our eminent telegraphists are not present this evening. It certainly is a very interesting paper. For a long time, telegraph authorities have been of opinion that the day of mono-telegraphic work is past; that the cost of using the telegraph circuit and maintaining it is so great that we must be able to utilize it, and multiply its use by making it answer for more messages than one at the same time. In bringing before us this interesting paper, Lieutenant Patten has unquestionably given us something which represents the beginning of the future, and you certainly should not lose the opportunity of giving it a thorough discussion.

Mr. P. B. Delany—I have to compliment Lieutenant Patten on the very clear and entertaining discourse he has given on a very interesting subject, and a subject in which I have had some experience. I would ask Lieutenant Patten, how many contacts to the line he proposes to give for each Morse circuit, so as to make the circuit sufficiently continuous for the manipulation of the average Morse operator. I didn't catch clearly the number of pulsations per second that he proposed to apply to each branch circuit with his distributors.

Lieutenant Patten—The question cannot yet be answered with all the definiteness I would like to give it; but, in general terms, I would say the number of segments given to each operator necessarily depends upon his speed. I would simply say that we have four contacts to a line. We have made a sounder work with clear action from an artificial line, of course, at the rate of 30 words a minute. There are two things which determine the number of contacts to be given to any operator in the circumference of a distributor; one is the speed at which the trailer is driven, and the other is the amount of time that the trailer rests in contact with the segment. Four contacts give a good reliable result; that would give about 1200 pulsations per minute.

Mr. Delany—The object of my enquiry was to ascertain the number of contacts that could be given to each operator, and at the same time afford the necessary duration of contact between the distributing trailer and each segment, and enable you to transmit currents over a line of a considerable resistance.

Lieutenant Patten—That is a refinement of the subject which can only be determined by prolonged experiment. I would say that with a few thousand ohms resistance we could get lower than $\frac{1}{400}$ or $\frac{1}{500}$ part of a second from a single contact.

Mr. Delany—You say that with 1200 contacts a minute, you get a sufficiently continuous circuit?

Lieutenant Patten—So far as our experiments have indicated, which are on an artificial line.

Mr. R. W. Pope—It is my impression that Mr. Delany's experience does not quite coincide with that of Lieutenant Patten, in regard to that contact, and I would like to hear what Mr. Delany's experience has been as to the number of contacts per second necessary to permit of fast Morse manipulation on long wires.

Mr. Delany—My experience would lead me to believe, in a general way, that on a circuit of, say, 100 miles, from New York to Philadelphia, for instance, with perhaps 1200 to 1500 ohms resistance, and an iron wire of a capacity, probably, of 1½ or 2 microfarads, that about 500 impulses per second can be transmitted over such a line and received on segments corresponding in position in the circle on a circuit table, provided the trailers and the distributor are in synchronism, and allowing a slight moment of time for the retardation of the circuit. If the retardation amounts to $\frac{1}{500}$ part of a second then the current sent at one segment in a particular position in the circuit will be transferred to the segment next in the direction of the revolving trailer. After each impulse has been sent into the line, the charge that is in the line delays the next impulse that goes into the line, and delivers it in a segment still further removed at the receiving end. I have found that in the operation of Morse circuits, what we call good Morse circuits, it requires at least 35 or 36 impulses per second to make a smooth circuit, so that the operator manipulating the key, as is frequently done, at the rate of 12 to 15 times in a second, may transmit to the full measure of his ability, or say, 40 words a minute.

On such circuits with that number of contacts in a second, I have seen more than 40 words transmitted for a considerable period of time continuously, say, for half an hour, over circuits about as I have described. In order to do that it requires a circuit that varies not more than $\frac{1}{1000}$ part of a second. If there is variation in excess of that, the currents become so weak that the relays would go out of adjustment, or it would be very sensibly felt at the relays at the receiving station.

Lieutenant Patten—Mr. Delany has remarked upon a feature that it might be of interest to mention in connection with this system. I might have put it into the paper; but, as I have said, I did not care to go particularly into detail. There is an essential difference between the system as shown here, and any system that is founded on the isochronous motion of different moving parts at different stations. For instance, if the instruments were driven by an isochronous machine and were absolutely synchronous, the two trailers would be at the same angle of position at the same instant; and if an electric impulse were sent over the line, and it took any time to reach the other end of the circuit, it is evident that the trailer would have left the position where it was when the impulse started. In a system of this character where synchronism is maintained—variable—you might describe it as transmitted synchronism; the trailer is just as much behind the initial one at the receiving station in time as it requires the current to reverse the line. These refinements are somewhat delicate, but if there is such a distinction, it is evident that we have more chance of getting the current out in a system that is varying than in one that is isochronous. I merely bring this point out to show the difference between synchronism independently maintained and that maintained by the circuit; I would like to ask Mr. Delany what he used for the circuit he describes working the old Morse instrument; I would like to ask what E. M. F. he used?

Mr. Delany—We used about 75 volts on the circuit. I mark the distinction that Lieutenant Patten wished to draw as to synchronism that is maintained by machines that are not isochronous in their movements, and that such synchronism in his system, is maintained by transmitted impulses. I would say that the synchronism with which I have had experience is also maintained entirely by transmitted impulses, that is, the synchronism is not maintained in any way by the isochronous method, independent of the two machines. One machine is corrected in its movement by impulses transmitted from the other end of the line, the receiving machine is corrected by the transmitting machine, and vice versa. The impulses are sent in opposite directions at different periods of the rotation of the trailer, so that if the current is sent over segment No. 1, we will say, at station X, and if it takes the time represented by the distance from No. 1 to No. 2 segment, to reach the receiving end and the correcting impulses which keep the instruments in synchronism maintain that relation and position of the trailer. We have found it necessary in practice to maintain the instrument in synchronism on corresponding segments, where it was necessary or desirable to telegraph in opposite directions simultaneously. Because you will readily understand that if segments at each end of the line are connected to operator A, and one operator is sending to the other, and the instruments are in synchronism and get the time of the impulses over the line as represented by the time of the trailer from one segment to the other; it will readily be understood that if A be sending to B, and the instruments are in synchronism for that condition, if B should turn around and send to A, A would not receive the impulses that were sent to him. Consequently, we have two synchronizing and corresponding segments if we wish to work in opposite directions simultaneously. So that you find the segment representing the time on the line at the receiving end connecting the operator to that segment and holding the instrument in that relation, the time of the impulse from each operator being the same. But where the time on the line is such as to make the transfer more than the margin allowed (than the variations of the instruments on the face of corresponding segments), you cannot work in opposite directions simultaneously.

Mr. C. J. Kintner—I desire to call attention to the fact, which Lieutenant Patten appears to have overlooked in his description of his apparatus, that it is, so far as I am aware, the first apparatus by which isochronous movement is effected by the apparatus itself. We all know the old Casselli system, which is perhaps the first isochronous telegraph with which we are familiar, in which the isochronous movement is brought about by the movement of a pendulum. In Mr. Delany's system, with which we are all familiar, that is done by the harmonic principle. In Lieutenant Patten's system, it depends upon the peculiar phases of the alternating current generator, and an alternating current motor of the same capacity or same efficiency, so that the two motors in all positions are dependent on the two phases in those positions. It was my good fortune last summer to make a somewhat extended set of tests and experiments upon Lieutenant Patten's apparatus, as to its efficiency and as to the isochronism of the apparatus.

I found that the machines ran uniformly in synchronism; and during the experiments, a very interesting feature came out. We were using six sets of keys at each end of the line, and I tested with all the keys closed at each end, one key closed, and successive keys, and various numbers of keys, closed to see whether there was absolute synchronism. I discovered that when key No. 1 at section No. 1 was closed at each end, there was a faint response—if closed on section No. 1, there was a faint response on section No. 2. I called Lieutenant Patten's attention to it, for the reason that I could not understand it. At last upon close examination of the trailers, I found that they were set slightly at an angle, so that as the trailers passed off section 1 they were slightly passed on to section No. 2, so that we had a response on the other section, which was an absolute proof of the synchronism of these two sections. I desire to call attention to the fact that the apparatus is capable of operation, as the Lieutenant has advised me, with an alternating current, in which it is possible, as I understand, to transmit messages over longer lines, because that with an alternating current he is able to discharge the line more rapidly.

Mr. F. B. Crocker—Lieutenant Patten has spoken several times about variable synchronisms. It is perfectly correct; but it sounds rather startling to the ordinary hearer, because the idea naturally is that synchronism is constant, and he makes the distinction between synchronism and isochronism. There is a distinction, of course, but he did not explain it very fully. Synchronism means that the two instruments revolve together whether fast or slow, whereas isochronism means that they revolve together at a certain speed. With a variable synchronism he may start off two instruments revolving together at 100 revolutions, and he may work up the speed of both at the same time to 1000 revolutions, and they will run synchronously just the same as the two driving wheels of a locomotive. In that way we have a variable synchronism. I think the confusion that might arise on this distinction is worth pointing out.

Lieutenant Patten—Mr. Crocker's distinction is quite correct. I had intended to bring it out; but perhaps did not do so quite clearly enough, but the distinction is in further illustration of my paper, and I thank him. In working the instruments, we try to drive them at a rate as uniform as possible. I brought out this idea of variable synchronism as a distinguishing feature of the system, not as one that would necessarily be used to a large extent. If machines are running at a good speed, a uniform 100 or 200 revolutions per minute, they are isochronous machines, and, of course, synchronous also. But if their speed is changed, they are no longer isochronous for the time being, they are simply synchronous.

Mr. Davidson—Mr. Kintner has suggested that the Delany system was based on a harmonic principle. I do not so understand it. As I understand it, no question of harmonics is involved. The circuit breaker is employed to control the rotation of the motor at either end of the line. That circuit breaker, it is true, may be a fork, it may be a rotating wheel; that is entirely immaterial. There is no question of harmony about it. As the circuit breaker makes and breaks the circuit of the local wheel at the end of the line, what is after all a small electric motor is rotated; that is, the passage of the pole on the disc or armature in front of a magnet coincides with the break in the circuit; that produces the rotation. Now the character of the impulse sent from one station to another merely modifies the circuit breaker; it slows it or accelerates it, and the two instruments are thus tied together: I do not understand that it is at all analogous to a harmonic telegraph.

Mr. Kintner—I accept the suggestion; I simply wanted to convey the idea that in Mr. Delany's system, like Casselli's, the synchronism was maintained by an extraneous apparatus.

The Chairman—We have with us this evening a gentleman who knows something of multiplex telegraphy in Europe, our friend, Mr. Abdank-Abakanowicz.

Mr. Abdank stated that he had never made a special study of telegraphy, but he had examined with great interest the synchronous devices of Lieutenant Patten, and was impressed especially with the performance of the motors running in synchronism.

Mr. Delany—When Mr. Davidson referred to the making and breaking apparatus, I was going to make the description a little more clear by stating that it was an automatic circuit breaker originally, a tuning fork in connection with what is known as the phonic wheel; that is perhaps where Mr. Kintner inadvertently got his idea of harmony. My synchronous and my multiplex telegraphs are based primarily on the very ingenious contrivances of Mr. Paul La Cour, his automatic circuit breaker in connection with a phonic wheel.

The Chairman—There is a great deal of interest to be said on this subject, but as the time is passing away, we shall have to take up the consideration of the next topic, which is the notes on Mr. Acheson's paper, by Messrs. Jo. Stanford Brown and C. T. Child.

Mr. Brown then read the notes as follows :—

LIGHTNING ARRESTERS AND THE PHOTOGRAPHIC STUDY OF SELF-INDUCTION.

Notes on Mr. E. G. Acheson's paper,[1] *by Jos. Stanford Brown and Chas. T. Child.*

Having been requested upon very short notice to reopen the discussion on the highly interesting paper on "Lightning Arresters and the Photographic Study of Self-Induction" presented at the Institute meeting held January 8, the following hasty notes and queries are with diffidence offered for consideration. Truth alone is sought, and it is a matter of regret if any criticism should even tend to disparage the worthy endeavors of one who has so fearlessly grappled a problem fraught with such interest alike to both theorist and practical electrician.

After careful reading it would seem as if the subject might be approached with advantage from more than one standpoint, and that even somewhat different conclusions were deducible simply by rearrangement of the experimental data. We have given a submarine or subterranean cable, to each end of which at its junction with the main line a lightning arrester is connected in the most approved manner, figure 1, to determine why, in spite

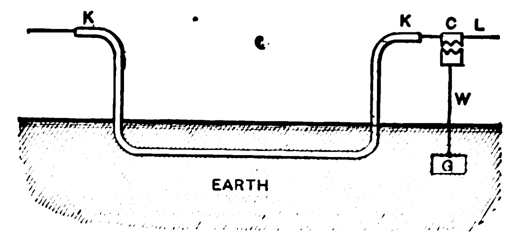

FIG 1.

of these precautions, the cable is not infrequently punctured when an "electrical discharge" enters the overhead system.

For experimental purposes this has been reproduced in miniature, as shown in figures 2, *2a*, *2b* and *2c*, by the line L entering

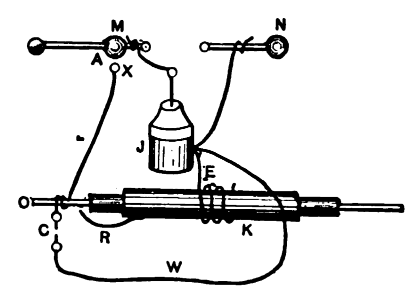

FIG. 2.

A and C constant.
B and W variable.
Capacity of J—.0025 m. f.
" " M and N not given.

the cable K at the point P, to which point is attached the lightning arrester C grounded through the wire W. The "electrical discharge" arises from the Leyden jar J, charged from the Holtz machine M N, and strikes the line at A. The outside of J will represent the earth, to which the ground wire W and the "earthing" of the cable, represented by E, "twisted a single turn"

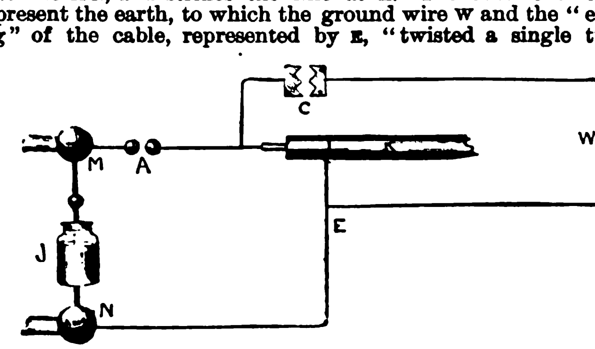

FIG. 2 *a*.

Case of a cable protected by a lightning arrester.

(*Western Electrician*, iv., 47) about the cable, is connected. Is it not possible, then, to throw figure 2 of the previous paper into the form figure *2a* for the purpose of drawing attention more directly to the relation of the circuits involved? The discharge, or momentary current, from the jar J entering at A traverses the

1. See ELECTRICAL ENGINEER, February, 1889, page 47.

line L to the point P, where two paths are offered; one, through the lightning arrester C to earth E; a second, in practice, by puncturing the cable insulation. C now being made but a fraction of the insulation thickness, and W a short, thick copper wire, it was found that the cable was still frequently punctured at times

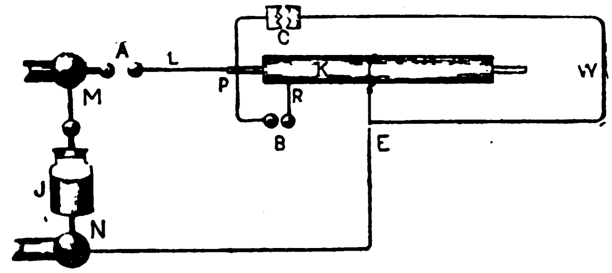

FIG. 2 *b*.

when a spark appeared at C, and that the length of W appeared to enter the effect equally with the space variation of C. *No part of the effect*, it will be noted, *is attributed to the action of the cable as a condenser.*

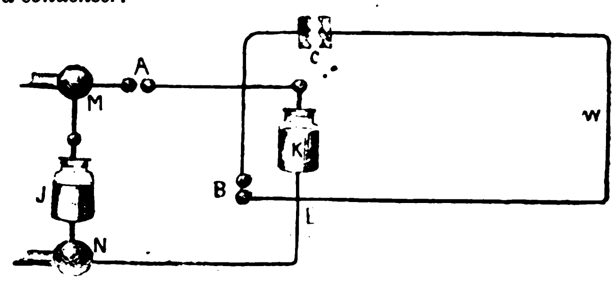

FIG. 2 *c*.

Equivalent to Fig. 2, with cable replaced by a condenser.

The problem is now changed to that shown in figures 3 and 3*a*, presenting a divided circuit with the lightning arrester at a constant distance of .02 inch and the earth wire W long compared with that connecting the variable B space with the same earth point. May not this arrangement of split circuit with an air space in each branch be looked upon as the general case for which Dr. Lodge's "alternative path" represents the condition of making

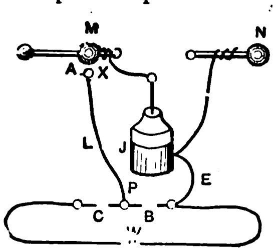

FIG. 3.

one of the air spaces zero? What then is the relative efficiency of changing the length of W and the distance of the C points *to prevent* a spark at B which represents the puncturing of the cable insulation, providing the B points are held equivalent to the long length of cable wire at any point at which puncturing may occur?

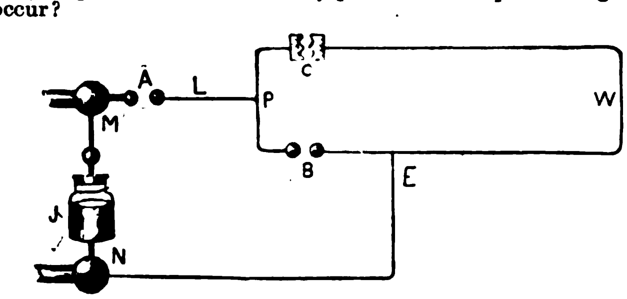

FIG. 3 *a*.

Fig. 3 redrawn.
A constant = 0.286."
C " = 0.020."
B variable.
W, of copper, .062" diameter, with variable length.

To decide this with A and C fixed at .286 and .02 inch respectively, B was varied with W to keep the spark ratio of B to A constant at one to 10. Then removing C (*i. e.* for C equal zero) the operation was repeated, and a comparison of these results is shown in the curve, plate A. Instead of this procedure, should not B have been made non-sparking for C and A fixed, and W varied until a spark was got at B, and then W left constant for variations of C up to a point where B would spark?

That with the connections of figure 4 and W equal 20 feet a spark should pass at B of over ⅓ inch in length might perhaps have been expected from Dr. Lodge's results (London *Electrician*,

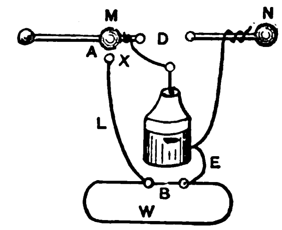

FIG 4.

xxi., 815), shown here in figure 4*b*, when there is an alternative path in which the self-induction of W (Lodge's L° loop) comes into play. True, figure 4 is not an "alternative path" of necessity, for the B points may be moved out of the sparking distance.

W is now supposed "electrified" by the charge across A. The "inverse extra current" of making simply cuts from the charging current; but the "direct extra current" of breaking, *i. e.*, charging impulse cessation, acts as its continuation but at a higher potential (Ganot, 7th edition, 776). This extra current then is running toward E and would naturally be supposed to equalize on the same path as the current generating it. It might, therefore, be expected to dissipate on reaching earth; the circuit is, how-

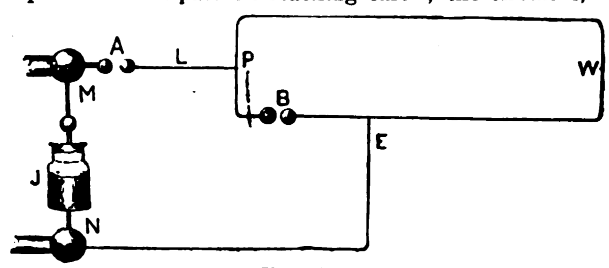

FIG. 4 *a*.

Fig. 4 redrawn.

C removed.
W = 20 feet of copper wire, .052" diameter.

ever, claimed to close itself through P W E B, or, more clearly, around the closed circle of the L° loop, figure 4*b*.

It would be of interest to some in this connection to know how it was ascertained that the instantaneous time duration of the extra current is shorter than that of the charging current; for if this be assumed, because of the known higher electromotive force of the former, the argument would seem to be in a circle.

On the assumption that the extra current dissipates through B, and not in the earth, it is argued that shortening W would tend to decrease this tendency to puncture the cable. To test this we have B equal the insulation thickness, C and W removed, and we get figure 2*b* if the C W circuit be supposed omitted. "With this

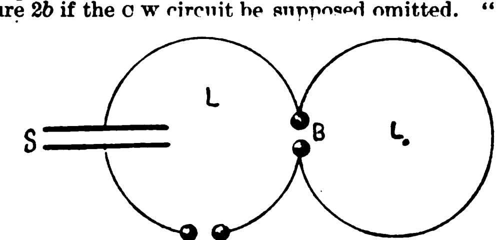

FIG. 4 *b*.

Cut of Dr. Lodge's Fig. 2, London *Electrician* (vol. xxi, page 815), showing alternative path.

arrangement it was not found possible to puncture the cable." May not this be regarded simply as a safety short circuit for our cable considered as a Leyden jar? And what is this but a working case of a cable effectually protected by a lightning arrester B? While the electrostatic capacity of a "short piece of cable" may be negligible compared with that of 20 feet of No. 16 B. & S. wire, it is perhaps doubtful if the capacity of a commercial cable could be so regarded in comparison with that of the ground wire from the lightning arrester.

It is not altogether plain how the direct extra current is an effect of Faraday's electro-tonic state when Faraday says (*Researches*, i., 16): "This state is altogether the effect of induction exerted, and ceases as soon as the inducing force is removed. And Jaquez ("Dictionaire d'Electricité et de Magnetisme," 1887,

p. 188) defines it as "the state of the conductor during the interval of time which separates the appearance and disappearance of an induction current." Maxwell, by the way ["Electricity and Magnetism" (2d Ed.), ii., 174], calls it "the fundamental quantity in the theory of electro-magnetism." Would it not be possible to regard it as an electro-magnetic potential stored in the wire ready to show itself as direct extra current? With the citations quoted above, how can this electro-tonic state exist *before* the electrifying current is discharged into the circuit?

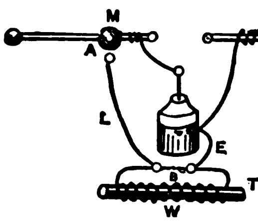

FIG. 5.

T=0.25" diameter.

Figures 5, 5*a*, 6 and 6*a* illustrate effects of different kinds of work introduced into the circuit. For references see Fleming's "Short Lectures to Electrical Artisans," pp. 44, 45, and Ganot, 7 Ed., 776; Maxwell, "Electricity and Magnetism," 2d Ed., ii., 211; Dove, Poggendorff's *Annalen*, vol. xlix., 1840, etc.

The methods used in the photographic part of the investigation would seem to cast some doubt on the results claimed. The effects noted deal chiefly with the prolongation or diminution of the current wave of the jar discharge by the secohmic resistance cut into the circuit. Might not a large element of uncertainty be introduced in the plates by the different degrees of illuminating power possessed by the sparks and by the irradiation of the plate?

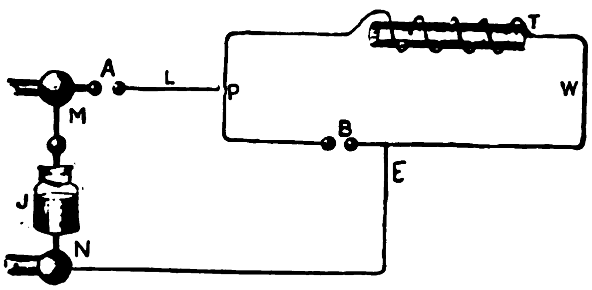

FIG. 5 *a*.

Fig. 5 redrawn.

In the cases when the discharges are through 76 and 20 feet inches of the same wire, respectively, hardly any difference appears in the spark. Is it not possible that the illuminating power of the quick bright spark through the short wire was so much greater than that of the necessarily more extended and consequently fainter spark through the long wire as to make the effect practically the same?

In the experiment in which two spark intervals are included in the circuit, as against one, formerly, it was found that the spark was materially lengthened. This might be expected considering the practically infinite resistance of the second air space which is introduced. The spark length too was found inversely

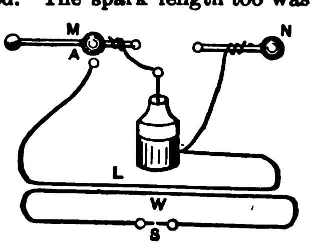

FIG. 6.

Length of parallel portions of circuits, 35"; distance separating them, 0.052."

proportional to any form of work introduced in the ground wire circuit. Possibly the photography of spark durations is not altogether the best method of measuring them. It is not yet by any means certain that a sensitive plate is equally affected by small equal time intervals at the beginning and end of the exposure, nor is it improbable that with sharp-edged holes moving at an extremely high velocity some diffraction phenomena might intervene that would introduce serious errors in the photograph. It is, besides, very difficult to measure the faint trails of light left by the spark. On the negative they are practically invisible, and in the prints their extreme delicacy and the fact that they fade away into the surrounding blackness without any sharp line of demarcation renders them almost impossible of measurement. On these grounds the measured spark distances of the first part of the article are probably more trustworthy as a basis for theory than the photographic results of the second part.

Returning to our original problem, why may not the cable, acting as a condenser, puncture itself in discharging, it having

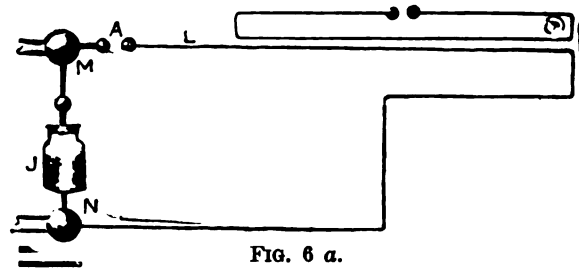

FIG. 6 *a*.

Fig. 6 redrawn.

been charged by the current from A, figure 2*c*, which, meeting the lightning arrester, backs up its potential until able to strike across and thus to ground? This discharge occurs simultaneously with the spark at C.

If a wave of current be pictured passing along a linear conductor, it would probably appear something like figure 7, its front

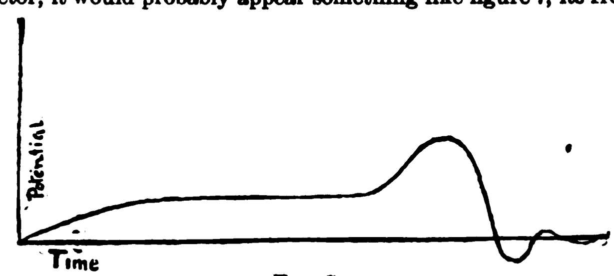

FIG. 7.

Form of current wave.

lengthened out by the self-induction effect of the cable, while the tension in the rear part is raised by the direct extra current. This high potential wave crest moves along the cable until, finding a weak spot in the insulation, it discharges rather than keeps up its strength with the impeding current ahead of it.

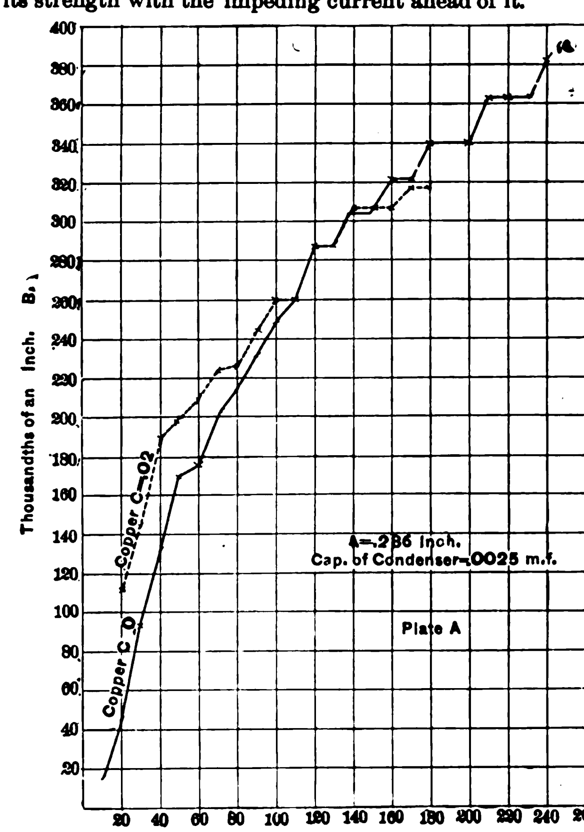

PLATE A.

We hope to be able to present at some future meeting the results of certain experiments delayed so far by pressure of professional engagements.

The Chairman—Gentlemen, these interesting notes are now before you for discussion. It is to be regretted that Mr. Acheson is not here, because he is so familiar with the subject; however, as the authors promise us a paper at a future meeting, we feel quite certain from the foretaste that they now give us that the paper will be of great interest. The subject-matter of these notes is one that is now receiving a great deal of attention all over the world, particularly in England, on account of its great bearing upon transmission through cables, and more remotely on the effect it has in all underground work. Consequently, it is a matter which is well worthy of study by electrical engineers in general, as well as of specialists.

The Secretary—I may say that these notes were prepared with a view of presenting the points for future criticism; for that reason the paper was presented in its present form, to be elaborated at some future time.

Mr. Abdank will be pleased to give some information with regard to an electrical headquarters, which it is proposed to establish at the Paris Exposition. He has spoken to me about it, and asked me to present the matter, but I would like to have him explain it himself, I think he would do it better.

Mr. Abdank—We have this year an Exposition in Paris, as you know, in which there will be a special section devoted to electricity, and I am in charge of that section for the United States. I have collected a very good exhibit, and I suggested having in the American section, headquarters for the electricians of the United States. We will have there a collection of all the electrical papers published in the United States and the books published here, and then we will have a special attendant there, who will have in charge a register, where the members of the electrical societies can come and find necessary information; and I would suggest that the society here give us for the Exposition a collection of the proceedings for its headquarters, and a book wherein the members of the society arriving in Paris may inscribe their names. We shall have a special box for the reception of letters addressed to members, and any member intending to visit the Exposition can have his letters delivered there, by simply having them addressed to "Paris Exposition, American Section, *Box Electricale*." Our office boy will put all the letters in order, and we will distribute them to the members arriving in Paris.

The Secretary—The council, as you are probably aware, has arranged to supply a set of proceedings to the Exposition, and I presume they will act on Mr. Abdank's suggestion and furnish a register for the recording of names.

The Chairman—I have no doubt that the subject will be taken up in due course by the council, and that our secretary here, with his usual eye to everything relating to the welfare of the society, will see that the matter is attended to in the proper manner.

MEETING OF MARCH 12.

The March meeting was held in Professor Doremus's lecture room in the College of the City of New York, Mr. T. Commerford Martin, vice-president, in the chair.

Having called the meeting to order, the chairman said :—

In the absence of our secretary, Mr. Ralph W. Pope, who is unfortunately detained by sickness in his family, it devolves upon me to introduce the business of the evening. I have much pleasure in announcing as the subject of the evening, "The Efficiency of Methods of Artificial Illumination," the paper upon which will be read by our fellow member, Professor E. L. Nichols, of Cornell University, and I have now the pleasant duty of calling upon the Professor for his paper.

Professor Nichols then read his paper, on "The Efficiency of Methods of Artificial Illumination." (See page 158.)

DISCUSSION.

The Chairman—Gentlemen, I am sure that you must have heard with the greatest pleasure the very able paper of Professor Nichols, and I think that it invites us to a very full and free discussion. We have with us this evening a number of gentlemen who are interested in this subject, both from a scientific and commercial point of view, and some of them have had practical experience in the inadequacy of the candle-power test to express the light-giving capacity of a lamp, and they have had some difficulty in convincing city councils and other bodies of that fact.

Mr. F. R. Upton—I think that we have heard a paper which puts the insufficiency of the candle-power test more clearly than it has ever been put before. I never have heard it expressed so clearly. I never have heard before so good and full an expression of what candle-power means. For the last few years there has been much discussion regarding candle-power. What Professor Nichols has said as to the amount of light that a low candle-power would give for illuminating purposes is very striking. Observe fire, and you will notice how it will illuminate the buildings around, and yet the candle-power is low. Where you have a glow of coal, the candle power is very low, yet the illuminating power, that you can see by, is very large. As to the artificial or fixed method of rating candle-power, I consider that the present custom of calling an incandescent lamp 16 or 20 candle-power is entirely wrong. Incandescent lamps are simply sorted. You put them in at 100 volts or 105 volts, so that they will be even if burned. That is all it means practically. Each consumer of light should fix the candle-power to suit the conditions. The marking that is now done on incandescent lamps is merely nominal; that is, it is in the hands of the parties who use the light to make the candle-power as much as they like.

I wish to express my pleasure at the production of such a paper as we have just heard. It is of the class that we want. We want more of them in these meetings. It brings to us the results of laboratory work, such as is now being carried on at Cornell, and when we can get such papers we can count ourselves very fortunate.

Dr. Otto A. Moses—The concluding remarks of Professor Nichols open up, I think, the proper field for us to cultivate; that is, the method by which we can arrive at some photometric standard. The method that he proposes has one very great difficulty. Carbon depends for its atomic condition upon the degree of temperature at which it has been distilled; that is to say, with every degree of increase of temperature you get an increase of carbon in the contents of the filament, the hydrogen being driven off. There were some experiments carried on in the laboratory where Professor Nichols and Mr. Upton were at work, by Professor Young, of Princeton, in which he determined that with an increase of incandescence in the filaments there seemed to be a diminution in the hydrogen of the filament, up to the point of the destruction of the filament, when the hydrogen seemed to disappear. That observation was made by him, and I think by Professor Brackett, proving that you are getting an increase of density in that carbon filament for each degree of increase of temperature. If you are to have a standard for photometric capacity, that standard should also be a definite heat capacity. The amount of light given off for different metals would vary according to that capacity, and you are getting for each increase of temperature in the production of that carbon filament a different degree of density, and consequently it would be impossible to take the dimensions and amount of current consumed and from those two deduce the limit of candle-power. The experiment where light was decomposed seems to be perhaps the most pregnant one for us to derive a photometric method from; for as in the decomposition of light we could recompose after we had determined the limits of action of each one of the colors of the spectrum, it might be possible in that way to get some definite summation. If it were possible to surround the light-giving centre with some sphere consisting of a film of definite thickness and containing a certain quantity of a substance to be acted upon by the light, it would be possible by superposing such films, to get, I imagine, what would be the summation of the chemical actions of all the different colors in the spectrum. In that way, by dissolving out from this film the soluble portions and determining the insoluble matter, it would be possible, by a chemical method, to arrive at the total chemical action on all those films and in that way make some definite approach to what is the real energy expended by the light.

Professor Nichols—If you are not all quite tired of me, I think I could perhaps make the last point a little clearer. The slide did not quite do its duty there, I think, in bringing out the relationship between the various wave lengths of radiation of four lamps all of which give the same candle-power, and from that I think I can indicate to you the line along which I would suggest a change of standard. I will take a piece of chalk and draw a diagram which will perhaps will be a little clearer. (Professor Nichols here repeated figure 10 on the blackboard.) The spectrum is assumed to be of unit intensity throughout. This is the yellow (indicating); here is the red; out here is green, blue and then violet, which is the limit of the spectrum. Now, if you have lamps of the same type of carbon, we will say—to illuminate all these questions that Dr. Moses suggested as to different carbons—this state of incandescence is that which corresponds to a 16 candle-power lamp of to-day. Take this same lamp and run it at a temperature which corresponds to a 4 candle-power to-day, and make that lamp large enough so that the photometer says it gives 16 candles, we find a curve like that which I had in my diagram, of this variety. Here are two lamps, one 16 and the other 4 c. p., and the photometer says that they are the same, but they are not the same either in total amount of energy, as one of my tables showed you, or in luminous effect; and if we run that on to 28 candles we find the red very much weaker, and the blue correspondingly much stronger. And there are three lamps, all of which the photometer says gives 16 candles, and yet they vary in total luminous energy and in total light-giving value as measured by their luminosity. At any rate, for a single type of carbon, prepared according to a certain process, and I believe it will hold through very closely of all filaments, if you know the state of incandescence, the temperature and the radiating surface, you have got a complete definition of the performance of that lamp, and you can then express exactly what it will do for any purpose for which you design it. If you want colors you use it at high incandescence. If you want the greatest possible reading power you will get a maximum for that also. You may have lamps which will give very different values when measured in these more exact ways, and which give the same value by the Bunsen photometer.

In the case of the 16 candle lamp raised to 50 candles, amounts to 10 per cent. As between the incandescent lamp of 16 candle and the arc light, the ratio between candle-power and luminosity is 4 to 5 merely. When we come to compare candle-power with daylight, one is half as good again as the other, and the ratio is 4 to 6. That is, a man who would give us 16 candles of a light like daylight would be giving us practically half as much again as he would give us with 24 candles. The man who gives us candle-power for candle-power of light of the quality of commercial arc light, as 5 to 4, 16 candles of his light are worth 20 of the 16 candles of the incandescent lamps. He who brings his incandescent lamp to a state which corresponds to 50 candles, gives us about 10 per cent. more, measured according to the luminosity, and yet we still are satisfied with the candle as our measurement of the performance of lamps.

Mr. Joseph Wetzler—Professor Nichols has outlined in a suggestion the method which he would pursue to get at the correct method of measuring the illuminating power of the lamp, and his method would consist in obtaining the radiating surface of the filament and its temperature. I would like to ask if he has attempted any practical way of carrying that out. Naturally it would seem that the determination of the radiating area of a filament would be easy to accomplish, knowing its size and the contour of its surface, and then would come the question of the temperature of the filament. It strikes me that if we knew the rate of variation for any particular carbon, the rate of variation of resistance for the increase in temperature, that that might be comparatively easily accomplished. I would like to know if Professor Nichols has worked in that direction. We would have merely to measure the resistance of the carbon; by a method similar to that of the Siemens pyrometer we could obtain its temperature, and then, having the temperature and the area, we could get at the value which he suggests.

Professor Nichols—I have been very much discouraged from attempting that, on account of some very singular results which Professor Anthony obtained some years ago, and which I think he reported to the Institute at that time, in the matter of the behavior of incandescent lamp carbons as to resistance at high temperatures. He came across a number of lamps in which the curve of resistance with increase of temperature turned upon itself. (See ELECTRICIAN AND ELECTRICAL ENGINEER, page 245, vol. vi.) Phenomena of that kind rather deterred me from that method of getting at the temperature of the carbon. But I think there is a hope of getting an optical method—an instrument by which you can look directly at the light and see what is its temperature in degrees centigrade. I think it would be premature to speak of that now, but possibly at some future meeting I may be able to report progress on it.

Dr. Moses—Mr. Upton, I am sure, will be able to answer some of these questions for us. In the manufacture of carbons from bamboo, the carbons are made of certain dimensions. They are then submitted to approximately a definite temperature, but it is found that they vary considerably in their resistances. Nevertheless, being of the same dimensions, and the carbon, when rendered incandescent, being brought up to certain definite temperatures for definite amounts of current, irrespective of the resistances in the beginning, it would seem that when definite amounts of current were passing, that in spite of this variation in resistance you would finally get the same amount of light, having these dimensions and the same material to act upon and the same temperatures ultimately; the temperature in this case being brought about by the current. Now, would Mr. Upton tell us about what would be the variations in carbons when of the same dimensions—when any given lot of them are put into lamps?

Mr. Upton—The ohms vary, of course, from accident. The one constant is the candles per horse-power.

Dr. Moses—But a definite fact is the amount of current that you allow to pass through them in testing them for their illuminating power. If you were to allow a definite amount of current to pass through those lamps, would you not approximately get the same amount of illumination, irrespective of the initial variation in resistance?

Mr. Upton—You are stating in a few words a pretty large problem. Of course, the question of the quality of the carbon comes in in a very large degree. The one constant, as I said, is the candle per horse-power. The carbons will vary, of course. Referring to what Professor Nichols says about the falsity of photometer measurements, many of us know that where lamps run a little bright how much more effect can be gained for certain purposes. A greater effect would be obtained for certain purposes far in excess of the increase of candle-power. That has been noticed in store lighting where colors come in, and Professor Nichols has explained it. There is another point about lighting that was not mentioned, and that is that there is a physiological effect of lighting; we used to notice that. The moment you get lighting up to a certain brightness, it has a cheering effect. If you get it dull it has the opposite effect, though both may be giving the same candle-power.

Dr. Moses—When you take carbon filaments of definite dimensions and bring them up, say, to a power of 48 candles and keep them there for some time, you then cook them and get them at just the very condition at which you can make these tests. Now, by passing a definite amount of current and bringing them up to the temperature as closely as we can calculate that will give 48 candles, would you not then get the same amount of candle-power from all of these? That question answered would determine whether it was possible to use this filament as a photometric standard.

Mr. Upton—As I said in reference to using a filament for a photometric standard, carbon varies in its surface, and you must specify your carbon and specify its carbonization before you can take that as a standard. You take a black carbon or gray carbon or polished carbon, and all the grades running between those, and you will have a variation from the same amount of surface in candle-power. The dimensions do not fix the candle-power. It is the quality of the surface that fixes the candle-power to a large degree.

Dr. Moses—But may we not get the right quality of surface by bringing the filaments to the same high intensity—by using a definite amount of current and then determining whether those carbons do not furnish at the same amount of horse-power consumed the same amount of light?

Mr. Upton—No. Take a thin flashed carbon; you bring that up highly and lose some of the flashing, and that has changed its quality; but the power that it will take to give light will change. There is a constant that runs through incandescent lamps that depends on the surface. Temperature does not fix it, as far as I know. But to measure the temperature of the filament itself is a very difficult matter. I do not know how to do it at present.

Dr. Moses—In making filaments from vegetable fibre, care is taken, I believe, to have them all from the same radial distance from the axis of the plant, so we may consider that the material is homogeneous and uniform. When we raise a body to a high temperature, we drive off by distillation those substances that may be distilled off, and if we get a definite amount of temperature by putting a definite amount of current through a definite parallelopipedon of carbon, then we will get a definite amount of illumination. Now, would not all carbons of the same dimensions —all similar carbons—give exactly the same amount of light? My reason for pressing the question is to determine whether the suggestion of Professor Nichols may not ultimately be taken as the definite photometric standard.

Mr. C. O. Mailloux—The constitution of carbon as found in the incandescent lamp is largely artificial, and is dependent greatly upon the method of treatment of the lamp. The value of a carbon filament would depend, other things being equal, on the density of the carbon. Its density has some relation to its color, and, again, the color has some relation to the condition of the surface, whether granular, crystalline, or smooth and polished. It occurs to me that this point of the density of the carbon will have some weight in the problem of the efficiency of incandescent lamps, and I have thought so ever since that paper was read by Professor Anthony, which Professor Nichols alluded to just now. May it not be that this variation of resistance in the incandescent lamp filament is one which instead of being abnormal is perfectly normal and characteristic of the carbon? I mean, of course, carbon in a highly incandescent state. May it not be that the resistance of the carbon is a function of its density—that it varies with the density of carbon as a material, and that this attains a minimum at a certain point. Now, the reason I speak of that is that I am brought to it by a certain analogy with substances which are perfectly familiar to us—electrolytes. I have had considerable experience in electrolysis, and in connection with that kind of work have had to determine the specific resistance of a great many substances, and I find that a great many substances have a particular density at which they give the minimum resistance. For instance, with sulphuric acid, you find that the curve is a very peculiar one, and that a very small increase at first in specific gravity, where you start with pure water, will make a very large decrease of resistance, but that by the time you reach a specific gravity of 1.2 you have reached very nearly the minimum; and if you go beyond that, the resistance increases, and finally when the sulphuric acid is at its maximum density its resistance becomes quite high; and the curve which it traces presents a very striking analogy to those which Professor Anthony presented before the Institute in his paper read last May. May it not be that we have here to deal with a phenomenon which is entirely normal, and that when we once determine the particular law which would appear to be involved here, we would have right there a means of measuring the efficiency of the lamp? With the current used in it and with the temperature and with a great many other conditions, it seems to me quite evident that having found an expression for the law which connects the density of the carbon with the temperature or with the resistance in some way, that we shall have made some step toward the finding of a practical method of gauging the efficiency of incandescent lamps. As I understand it, Professor Nichols states that the ideal method would be one which would be based on the radiation of the energy from the filament of the incandescent lamp itself, and if that were the case it looks to me as though you must look right there for the path leading to the proper solution.

Dr. Schuyler S. Wheeler—It seems to me that the most import-

ant measurements to be made of lights are when they are actually existing—not to be predetermined; and for that reason I would like to know if Professor Nichols thinks that the sum of the photometer readings of a light in different parts of the spectrum represents its real value?

Professor Nichols—As I understand it, we have to multiply the photometer reading in each part of the spectrum by a factor which itself is a function of the wave length and which expresses the light-producing power of that particular wave length. You have a light of a given kind. You see the distribution of energy in the spectrum from the violet to the red, and you take the sum of those wave lengths right down; taking the integrated value of this energy; that is, the area enclosed by the curve; that is the quantity which I speak of as the total luminous energy or radiation; but that is not the light-giving power. The light-giving power varies enormously in different parts. Part of the yellow, with slight variation so far as its actual energy is concerned, has a value representing several hundred times that of the extreme yellow, and out of the red we get great energy and little light-giving power; and at the end our luminosity ceases. We have to take the product of each wave length—of the amount of energy—into its luminosity as determined by one of the methods described; that is, the power which that particular wave length has in enabling us to read fine print.

If we have blue light and yellow light and bring them to the same brightness, so that to the best of our judgment we would say that they were equally bright, we can read fine print in the yellow and can not read it in the blue. In other words, the power of the blue to enable us to distinguish print is less. It is of no value, practically, for that purpose. What enables us to distinguish black characters on a white ground is the half of the spectrum which lies toward the red, and the rest might as well be thrown away. In almost all uses that we have for the electric light this thing that Mr. Upton spoke about comes in—namely, that indescribable value which we cannot express; that thing which brings out the colors in the art galleries and in our rooms. That lies largely in the violet; so that I think the value of light increases with its incandescence faster than with its luminosity. It is a factor which must be determined for each case according to the purposes for which you intend to use the light.

Mr. Dobby—I would like to ask Professor Nichols if he has thought of a photographic method of determining this point. There are three points in the spectrum which could each be determined by a plate specially prepared for it. For instance, a dry plate can be colored by aniline dyes; it has to be specially sensitive to one particular ray. As the question of lighting is a commercial question, might it not be a practical thing to determine the power of the lamp in a special part of the spectrum by a plate, and give it that value and state in what part of the spectrum its value was given?

Mr. Birdsall—As it is known that ordinary silver salts are more sensitive to the blue and violet rays than to others, and almost wholly unaffected by the dark red rays, that would seem to give us a means of measuring the most desirable rays for colors, namely, the violet rays; but it is also a fact that good photographs have been taken in almost absolute darkness to ordinary eyes. In other words, the violet rays past the visible end of the spectrum have the power to affect the sensitive plate, and in that way in Germany photographs have been taken at night.

Mr. Mailloux—I believe that it will be found possible to measure the energy of the incandescent light. I have great faith in the calorimeter, and I believe in the method which was outlined this evening by Professor Nichols. I do not see that there are any physical impossibilities in the way of arriving at a method by which we can differentiate the several kinds of light and find out the law connecting them together. Having done this, then it occurs to me that we could express the efficiency with reference to the properties for which the light is to be used, and that we could have a formula—a sort of modulus—by means of which the varying conditions of the use of the lamps would be taken into consideration in estimating their particular efficiency.

The Chairman—It is long past our usual hour for adjournment, but we have very far from exhausted the subject. It is, in fact, impossible to begin to exhaust such a subject in an evening's discussion. I think we appreciate our own ignorance in dealing with such a subject. It is remarkable how far in advance our own speculations and ideas of the subject are of the ideas which are ordinarily entertained by the public, and while listening to the discussion this evening as to candle-power, I was reminded of an incident that occurred last week in Bristol, Pennsylvania, where one of the large drug stores of the town was illuminated by candle at the time of the starting of the incandescent lamp. The druggist had heard that the incandescent lamps were of 16 candle, and in order to show how poor and insignificant the new illuminant was, he decorated the whole of his window with 16 candles. The result of the illumination was not as great a success as he anticipated, and he was overwhelmed with offers of the loan of snuffers on all sides. Although the incandescent lamp compared so favorably with the candles that were shown by the Bristol druggist, I think we have before us a great deal to do with the improving and perfection of our arc and incandescent lamps in order to secure a greater efficiency and in order to be less wasteful. The lines of one of England's great poets occur to me in that connection. You may remember them; they are those in which Tennyson says:

> "Our little systems have their day,
> They have their day and cease to be,
> They are but broken lights of Thee,
> And Thou, O Lord, art more than they."

And when we can get our own broken lights somewhat nearer the perfection of daylight we shall have done some of the work which awaits us. Of course Tennyson, in speaking of "our little systems" having their day, did not have in mind the systems which we see in such rapid process of consolidation with other larger systems. At the same time I think he hinted at a very great and singular truth. Adjourned.

ELECTRIC LIGHT AND POWER.

The Edison Illuminating Co., of Brooklyn, through their manager, Mr. Field, has just awarded one of the largest steam engine contracts ever placed in New York, for 12 Ball automatic compound engines of 250 h. p. each, to Charles R. Vincent & Co., of 15 Cortlandt street. These engines will be placed in the new central Edison station in Brooklyn, and will mark the latest development in high speed steam engineering, it being Mr. Field's intention to make this plant a model one in every respect.

The Heisler System on the Pacific coast at East Portland, Ore., has made a stout fight with the gas company of that city, and obtained the contract for 125 30-c. p. street lamps. The circuits are said to be 12 miles in length, using No. 8 B. & S. gauge of wire, and it has been stated by local papers that the lights are very satisfactory to the council and citizens. The plant and circuits will be enlarged and extended by Mr. H. A. Hogue, proprietor of the central station, so as to enable him to furnish commercial and private house lighting from the same station. This makes six central station plants of the Heisler system on the Pacific coast, most of them furnishing street, commercial and private house lighting from one central station plant on very extended circuits.

The Electrical Accumulator Co. has completed installation of 112 "15A" cells with Otto gas engine, together with all necessary switches and appliances, in the elegant Chicago residence of Potter Palmer, of Palmer's hotel. The plant was turned over on February 18, everything working perfectly. The lamp service was remarkably good. Through the courtesy of Mr. Conant, representing the Electrical Accumulator Co., in Chicago, members of the Electric Light Association and visitors at the recent convention in that city were given opportunity to inspect the installation at Mr. Potter's house. Those who availed themselves of the privilege were much impressed with the success of the accumulator plant.

An Electric Transfer Table at Altoona, Pa.—The Sprague Company have recently installed an electric transfer table, operated by one of their electric motors, for the Pennsylvania Railroad, at Altoona, Pa. The motor is of 10 h. p., and its speed is controlled and the direction of rotation changed, by a Sprague patent switch, carried on the table itself. The power for operating the table is taken from the engine operating the main-shops, about 500 to 600 feet away from the table. Here there is stationed an Edison dynamo which generates the necessary current for operating the motor.

The Thomson-Houston Company.—On the 27th of February, the Legislature of Connecticut authorized the Thomson-Houston Electric Light Company to increase its common stock from \$1,000,000 to \$10,000,000, and to issue \$5,000,000 of preferred stock. In addition to increasing the capital, the resolution empowers the company to buy or lease plants for electric light, heat, power, or electric railways, and to buy stock and bonds of electric lighting and electrical companies, illuminating and carbon companies, and railroad companies whose roads may be operated by electricity.

The stockholders have been notified of a special meeting at New Britain, Conn., April 2, to determine, *First:* Whether the company shall increase its common capital stock by \$2,000,000, so that the total shall be \$3,000,000; upon the following plan: A—\$1,000,000, representing present earned and undivided profits of the company, as a stock dividend to present stockholders, one new share for one old share held, transfer books closing from April 9 to 14, inclusive, certificates of new stock to be deliverable April 15, such stock not being assignable before the issue of certificates, and rights thereto not being assignable. B—The other \$1,000,000 of increased capital to be sold and issued for cash, stockholders of record April 8 to have the right up to April 12 to subscribe therefor in cash at par, \$25 per share, one share of new for each share of present stock held. The rights to subscribe to this new stock are to be assignable up to April 12, after which stock not subscribed for will be sold by the directors for cash, not below par. *Second:* To determine whether the company shall issue \$1,000,000 preferred stock, making the total capital \$4,000,000, \$3,000,000 common and \$1,000,000 preferred, said pre-

ferred stock to receive seven per cent. per annum in dividends, payable semi-annually, to be sold for cash at not less than par, and to be issued from time to time in such manner as the directors may determine. *Third:* To appoint a committee to draft a new or amended code of by-laws, to be submitted for approval at the next annual meeting. *Fourth:* To see if the stockholders will vote to change the office of the company and the place of holding the annual and any special meetings from New Britain to some other place in Connecticut.

THE ELECTRICAL ACCUMULATOR COMPANY commenced a second suit in equity, February 15th, against the Julien Electric Company, charging infringement of the Sellon patent, for the use of an alloy plate in secondary batteries; damages and an injunction are asked for. The same corporation has also instituted suit in equity against the Gibson Electric Company on three several patents of Faure, Swan and Sellon, for improvments in secondary batteries.

Foreign.

Austria.—The "Unionbank," of Vienna, has made a preliminary agreement with Messrs. Ganz & Co., of Budapest, with the object of forming a large electric light and power company, under the title "Allgemeine Osterreichische Elektrizitätsactiengesellschaft." The bank offers to undertake the financing and floating of the company, the share capital of which is fixed at 2,000,000 florins (about $775,000), whilst Messrs. Ganz & Co. undertake the technical management and the supply of the machinery required.

The town council of the watering place of Marienbad have, at a recent meeting, unanimously resolved to adopt the electric light for the streets and all the municipal buildings, and the order for the installation was given to Messrs. Ganz & Co. The station is intended for the supply of 1,250 glow lamps in private houses and municipal buildings, and 35 arcs for street lighting. According to the present plans, the generating plant consists of two 50 kilo-watt alternators, each driven direct by a separate steam engine. The site for the station is about a mile and a half from the town, and the current is to be distributed by overhead wires. The transformers for the public lamps will also be fixed overhead, on posts, and protected by iron casings, as in the Westinghouse system. All the arc and glow lamps will be arranged in parallel. The total cost of this installation is estimated at about $38,000.

France.—THE ELECTRIC LIGHT AT THE BON MARCHÉ, PARIS.—At a recent meeting of the International Society of Electricians, M. Cance read a paper describing the electric light installation at this large emporium. This installation is interesting not so much on account of the machinery and apparatus employed as on account of its magnitude. It resembles rather a central station than a private installation. The total steam power employed amounts to no less than 900 h. p., and there are various types of dynamos in use, viz., Gramme alternators, Gramme direct current machines, and Edison machines. A great part of the lighting is carried out by Cance arc lamps placed in parallel on a 70-volt circuit, with additional resistance, to make them burn steadily.—*Industries.*

CENTRAL STATION LIGHTING IN PARIS.—The various schemes for the public supply of electricity in different quarters of Paris have been in abeyance for a long time, but there seem at last to be signs of progress. The municipality some time ago instructed M. Lyon-Alemand to examine the various projects elaborated by different companies, and on Saturday his report was accepted by the council. The following are the firms or companies which propose to have a share in the lighting of the town, each taking what is known as a "sector:" 1. La Compagnie G. Sencier; 2. La Société d'Eclairage Electrique de la Place Clichy; 3. La Société Anonyme pour la Transmission de Force Motrice par d'Electricité (Société Marcel Deprez); 4. La Société Continental Edison; 5. La Compagnie d'Electricité Victor Popp; 6. La Compagnie Parisienne Electrique.

Switzerland.—ELECTRIC RAILWAY IN BURGENSTOCK.—The track of this road is only some 3,000 feet long, but the difference of level between the two extremities is about 1,400 feet, giving thus a mean gradient of over 50 per cent. The gradient is not quite uniform, and the upper part gives a rise of 57.7 per cent. Water power is used and the transmission is effected electrically. The electrical plant has been furnished by Messrs. Cuénod, Sautter & Co., of Geneva. Two cars are used, which counterbalance each other, that is to say, one ascends whilst the other descends. The electric power, therefore, serves merely to overcome the friction of the apparatus and to counteract the differences of loads in the cars, and the power is said to be very variable. The current is generated by two dynamos, with a capacity of 30 h. p. The circuit extends over a distance of about 2½ miles, leading to two motors.

NEW INCORPORATIONS.

Electric Light and Power Co., Beardstown, Ills., H. Ehrhardt and others. Capital, $20,000.

Maywood and Proviso Electric Light and Power Co., Maywood, Ills., Joseph Jennings and others. Capital, $20,000.

Bankers' and Brokers' Telegraph Co., Steubenville, O. Capital, $50,000.

Bowling Green Electric Light and Power Co., Bowling Green. O. Capital, $10,000.

Baker County Telegraph and Telephone Co., Salem, Ore. H. C. Bowers and others. Capital, $30,000.

University Electric Street Railway Co., Denver, Col., G. W. Bailey and others. Capital, $75,000.

Thirty-first Street Merchants' Electric Light Co., Chicago, Ills., John McDermott and others. Capital, $20,000.

Benton Harbor and St. Joseph Electric Light Co., Benton Harbor, Mich., I. W. Conkey and others. Capital, $25,000.

Toronto Electric Light and Power Co., Toronto, O. Capital, $15,000.

Hagerstown Electric Co., Hagerstown, Md., Charles E. McKee and others.

Curtis Electric Light and Power Co., Portland, Me., A. J. Adams and others. Capital, $800,000.

Electric Liquid Controller Co., Richmond, Va., T. N. Motley, of New York, and others. Capital, $50,000.

Easton Electric Light Co., Newark, N. J., Henry D. Lyman, of New York, and others. Capital, $1,000,000.

Leonard and Izard Co., Chicago, Ills., H. Ward Leonard and others. Capital, $300,000.

Evanston Electric Light and Power Co., Evanston, Ills., John S. Philip and others. Capital, $30,000.

Municipal Electric Power Co., of New York, T. F. Hayes and others. Capital, $100,000.

Olympia and Turnwater Railway, Light and Power Co., Olympia, W. Ter., Edward M. Wilson and others.

Merchants' Electric Light Co., Seattle, W. Ter., Jno. D. Lowman and others. Capital, $50,000.

Millard Avenue Electric Co., Chicago, Ills., George Martin and others. Capital, $25,000.

Harvard Electric Light Co., Harvard, Ills., W. Fay and others. Capital, $16,000.

Jefferson Rapid Transit and Electric Lighting Co., G. H. Parker and others. Capital, $250,000.

Lewistown Electric Light, Heat and Power Co., Lewistown, Ills., L. N. Ross and others. Capital, $10,000.

Elkhart Electric Light and Power Co., Elkhart, Ind., J. N. Lumbert, president. Capital, $10,000.

New York Construction Co., of Chicago, Ill., S. G. Clark and others. Capital, 30,000.

Sperry Light and Power Co., Chicago, Ill., Sam'l P. Parmly and others. Capital, $100,000.

Gas and Electric Co., Middleboro, Mass., N. E. Wilbur and others. Capital, $30,000.

West Side Electric Light and Power Co., New York, Elsworth L. Striker and others. ———

Century Electric Co., Newark, N. J., T. G. Brown and others. Capital, $100,000.

Electrical Engineering and Construction Co., Chicago, Ills., M. E. Willard and others. Capital, $600,000.

Bogota Electric Light Co., Albany, Ills., A. Lagenvach and others. Capital, $100,000.

Maine Electric Light, Gas and Water Co., Rockland, Me., A. F. Crockett and others. Capital, $1,000,000.

Beverly Electric Light and Power Co., Beverly, N. J. Capital, $50,000.

Abington Electric Light and Power Co., Abington, Mass., J. R. Lovejoy and others. Capital, $25,000.

Troy Electric Dynamo Co., Troy, N. Y., Justus Miller and others. Capital, $20,000.

National Automatic Fire Alarm Co., Washington, D. C., Van H. Manning and others. Capital $350,000.

Taylorville Electric Light and Power Co., Taylorville, Ills., W. W. Andrews and others. Capital, $20,000.

Evanston District Telegraph and Electric Co., Evanston, Ills., F. M. Winters and others. Capital, $25,000.

Lakeside Electric Light and Power Co., Chicago, Ills., D. Barclay and others. Capital, $30,000.

Columbia Electric Light, Heat and Power Co., J. J. McEvoy and others. Capital, $15,000.

People's Electric Light Co., Chicago, Ills., John J. Curran and others. Capital, $50,000.

Merchants' Arc Light and Power Co., Chicago, Ills. Capital, $60,000.

Electric Street Car Motor Co., Chicago, Ills., W. S. Salisbury and others. Capital, $250,000.

MANUFACTURING AND TRADE NOTES.

MESSRS. SPAULDING AND BUCK, 620 Atlantic ave., Boston, have secured the New England agency for the "Eddy" motors. The same territory has been secured for the Continental dynamos.

THE ELEKTRON MANUFACTURING CO., of Brooklyn, N. Y., has opened an office at 150 Nassau street, New York, under the charge of Mr. E. H. Cutler, manager of the company. This company manufacture the "Perrett" motors, which have attracted so much attention of late.

THE EMPIRE CITY ELECTRIC CO., 15 Dey street, will now receive the benefit of Mr. E. T. Gilliland's extensive experience in the manufacture and sale of electrical supplies. The recent lease of a large factory is an indication of the scale upon which this company intends to do business.

THE FORT WAYNE JENNEY ELECTRIC LIGHT CO. has scored another victory in the sale of its alternating system to the West Side Electric Light and Power Co., of New York city. The West Side company has an excellent field, and the demand for lights has already far exceeded expectations. Mr. W. H. Cole is general manager and electrician.

MESSRS. J. ELLIOTT SHAW AND CO. announce that they have succeeded to the business of Messrs. Shaw and Geary, 53 and 55 N. 7th street, Philadelphia.

THE NATIONAL ELECTRIC MANUFACTURING CO., of Eau Claire, Wisconsin, announce that they are prepared to furnish an alternating system of incandescent lighting, having purchased the patents of Mr. Walter K. Freeman.

HILL CLUTCH WORKS.—Mr. Walter C. Wonham, manager of the eastern office of the Hill Clutch Works, 18 Cortlandt street, New York, reports that the business is constantly increasing, and that they have recently made large shipments of their friction clutches and power transmission machinery to the following points:—Buffalo, N. Y., New Brunswick, N. J., Boonton, N. J., Wilmington, Del., Schenectady, N. Y., Newark, N. J., Boston, Mass., Troy, N. Y., Peabody, Mass., Providence, R. I., Gardner, Mass., Ocean Grove, N. J., Paterson, N. J., Derby, Ct., Lawrence, Mass., Baltimore, Md., Baldwinsville, N. Y., Albany, N. Y., and New York city, and have booked orders from the Fitchburgh Steam Engine Co., the Cyclone Pulverizer Co., Edison Machine Works, the Pusey and Jones Co., the Robinson-Foster Electric Railway Motor Co., Narragansett Electric Lighting Co., F. W. Ehrsam, Benjamin Eastwood, the Derby Gas Co., Hewes and Phillips Iron Works, Jno. B. Adt, and the Lehigh Valley R. R. Co.

MESSRS. W. R. OSTRANDER & CO., 21-25 Ann street, New York, have introduced a new and simple door opener for apartment houses and flats. The movement is a gravity one, and it is devoid of any delicate springs or complicated mechanism. This door opener can be operated either by electricity or compressed air. Both forms are supplied by Messrs. Ostrander.

THE PHILADELPHIA OFFICE OF THE FORT WAYNE JENNEY ELECTRIC LIGHT CO., G. A. Wilbur, manager (lately at 26 N. 7th street), has removed to No. 907 Filbert street.

A VERY fine exhibit was made at the last American Institute Fair by the Jerome Kidder Manufacturing Co., 820 Broadway, New York, makers of Dr. Kidder's electro-medical apparatus. The company produces an exceptionally fine line of medical apparatus, batteries, etc. They have received the highest awards from the Institute since 1872. They show a full line of galvanic batteries, galvano-caustic batteries, many styles of faradic batteries for family and physicians' use, tip batteries, surgical instruments, cauteries and special appliances for a large variety of medical and surgical operations.

MESSRS. JAMES W. QUEEN & CO., of Philadelphia, who have gone so largely into the supplying of electrical testing instruments during the last few years, have done much to develop the home manufacture of such apparatus. Their rheostats and combination testing sets have already acquired a reputation for finish and, better still, for accuracy. Their high-class work is certified by Professor Wm. A. Anthony, a most satisfactory guarantee of its excellence.

THE WOODHOUSE & RAWSON CO., of London, announce the receipt from Melbourne, Australia, that a first-class award has been made to them for their display of electrical apparatus at the exhibition there.

MR. GEORGE O. FAIRBANKS has been appointed general district agent of the Westinghouse companies for the states of Illinois, Indiana and the Michigan peninsula.

THE WESTERN ELECTRIC CO., of Chicago, received an award at the Melbourne Exposition, Melbourne, Australia, for its exhibit of electric bells, annunciators, etc.

THE firm of Shaw and Geary, Philadelphia, has been dissolved by mutual consent. The electrical manufacturing business will be continued at No. 53 N. 7th street, under the name of J. Elliott Shaw and Co.

THE E. S. GREELEY & CO., of New York, have designed and manufactured and offer for sale a small and compact Wimshurst electric machine, with special reference to the wants of students and experimenters. They also provide convenient accessory apparatus and publish a tasteful little pamphlet (from which they have, too modestly, withheld their name) containing some account of the machine and its accessories, and directions for a few experiments. Such an outfit for the initial study of static electricity, or for entertaining experiments, is sure to be appreciated very widely in these days, when everybody wants to know something about electricity.

OKONITE wire is reported to meet with a brisk demand from all parts of the country. The Standard Electrical Works, Cincinnati, representatives of the Okonite company, have just closed a large contract to furnish the Cincinnati Railway Co. with Candee aerial wire for their main lines. The new Chamber of Commerce building, Cincinnati, has also recently been entirely installed with Okonite wire through the Cincinnati office.

MESSRS. E. E. GARVIN & CO., of this city, manufacturers and dealers in machinery, notify their customers and friends that they have secured a long lease of the new building at Laight and Canal streets, and will take possession about April 1. The firm's new quarters afford room for largely increased facilities for manufacturing. Their plant will be a modern one, and all necessary tools for the proper and expeditious finishing of work will be introduced as fast as required.

THE AMERICAN INDURATED FIBRE CO., Mechanicsville, N. Y., are in the market with indurated fibre pipe for underground electric wires. Good insulation, durability, lightness and low cost are some of the advantages claimed for the use of these pipes as underground conduits. It is also claimed that they possess a high resistance to the action of heat and gases.

THE DEATH OF MR. FRANK SHAW.

The death of Mr. Frank Shaw, on Saturday, March 23, removes a familiar figure from the ranks of electricians in New York.

Mr. Shaw was a Virginian. He was born in the western part of the state (now West Virginia) in 1841. He began his electrical work in the Construction Department of the U. S. Military Telegraph at the head-quarters of the Army of the Potomac. After the war he took service successively with the American, the Western Union and the Gold & Stock Telegraph companies, becoming well acquainted with the practical side of telegraphy and particularly with printing and other stock-reporting methods. He afterwards spent some years in the City Fire Alarm Department, where, as an inspector, he greatly increased electrical and mechanical knowledge and experience. Soon after 1870 Mr. Shaw turned his chief attention to exchange systems of communication, and soon connected himself with the Law Telegraph Co., whose successful enterprise in building up an exchange printing telegraph system in New York. Dial instruments were first used, followed by printers. The telephone displaced both, but Mr. Shaw's ingenious inventions of circuits and devices for exchange work were equally available for the new instrument of communication, and the Law company's telephone exchange became distinguished for its excellent service. Mr. Shaw continued with the Law Telegraph Co. up to the time of his death. His eminently practical notions and his ingenuity enabled him to produce a number of electrical devices of much utility and value. His cleverness was shown chiefly in his apt arrangement and combination of circuits for exchange service and in ingenious designing and construction of switches for their manipulation. Mr. Shaw's untimely death will be deeply regretted in electrical circles, particularly by his many personal friends, to whom his genial presence was always a pleasure.

ALUMINIUM.

Aluminium—is as everybody knows a metal. But the remainder of everybody's knowledge of it seems to be rather of the abstract than of the concrete order.

Since it is steadily growing cheaper, and is said to be now producible at about 25 cents per pound, the time seems to have arrived when it ought to be looked at with increased interest by electricians. Here, therefore, are some of its characteristics gathered together for the benefit of the readers, of the ELECTRICAL ENGINEER.

Aluminium—not Aluminum.
Symbol Al. Atomic weight 27.3.
Equivalent 13.7.

Al—belongs to the so-called aluminium group, which includes also indium and gallium.

It is the metallic basis of clay, and its name is derived from *alumen*—alum.

Was first prepared by Wohler in 1827, is a tin white metal, and capable of assuming a bright polish.

Can best be worked at a temperature of 100° to 150° and fuses at about 700°.

It does not oxidize at ordinary temperatures. Has a specific gravity—when cast of 2.56 and when hammered of 2.67; and is extremely sonorous, emitting when struck a sound like flint glass.

It is about as malleable as gold and silver; is ductile, and can be drawn out into wires of extreme tenuity. When so drawn into very fine wire it deteriorates, and has to be carefully annealed before it can be used.

Tensile strength—Taking the strength of aluminium in relation to its weight, it possesses a mechanical value about equal to that of steel of 35 tons per square inch, tensile strength.

Electrical conductivity.—According to Deville, aluminium conducts electricity about as well as silver; but Fremy states that the conductivity of silver being called 100; that of aluminium is but

83.74. There are also other estimates, and the discrepancies as above are wide, but they are probably due to some of the comparisons being weight for weight, while others are size for size, and it would seem that Deville's statement should be held as weight for weight, which would require a much larger wire of aluminium, and Lazare Weiller confirms this view since he gives the relative conductivities of pure copper, and aluminium in wires of like size as being respectively 100 and 54.2. This metal is also slightly magnetic.

Thermal conductivity.—Al'. conducts heat better than either silver or copper, and its specific heat is 0.2181, which is greater than that of any other useful metal.

Aluminium bronze, it is likely, will continue to be the form in which aluminium will be most interesting to the practical electrician and electrical engineer. This is an alloy of aluminium and copper, has a color like gold, is extremely hard, and susceptible of fine polish; it is very malleable, and has tenacity equal to fine steel. It is already much used on the Continent of Europe for telephone lines, and will doubtless be employed to a much greater extent as it can be made more economically. Its conductivity is, however, low, being as stated by Weiller, but 12.6, where phosphor-bronze is 29, silicious-bronze for telephone wires 35, and pure copper, 100.

CORNELL UNIVERSITY.

Recent additions to the equipment of the Electrical Engineering Department of Cornell University include the following gifts:—A storage battery of 70 cells from the Brush Electric Company, a storage battery of 60 cells from the Electric Accumulator Company, and a complete incandescent light outfit from The Thomson-Houston Electric Company.

Professor Frank Van Vleck, formerly of Cornell University, is now engaged in electrical business at Los Angeles, Cal.

THE TELEPHONE IN SWITZERLAND.

The returns published by the Swiss Confederation with reference to the development of telephonic communication in Switzerland show that, since the establishment of the first telephone in 1880, 61 towns have been provided with it, and there are now 6,944 telephonic stations, of which no fewer than 1,500 are in Geneva and its suburbs. Most of the Swiss towns are now connected with one another, Geneva communicating not only with Lausanne and other places on the shores of the lake, but with Berne, Zurich, and St. Gall. The Confederation has taken over the telephones, which are attached to the department of posts and telegraphs, and the annual cost of subscription is only £6. Notwithstanding this moderate charge, the receipts exceed the expenditure by about £8,000, and the federal council now contemplates reducing the rate of subscription to £5 for the first year, £4 for the second, and 80fr. for the following years, with a trifling supplemental charge for those subscribers who use the instrument more than 500 times during the twelvemonth.

POINTERS.

.... THE definition of energy is capacity for doing work. We practical men are quite content to start from this fiducial line, and to affirm that our electricity is a something which has a capacity for doing work; it is a peculiar form of energy. The physicist may speculate as much as he pleases on the other side of this line. —*W. H. Preece.*

.... IN the sale of the Waterhouse system by its owners to the Westinghouse people, a strong financial company will acquire a first-class incandescent system (!)—*Electric Mechanic*, Dec 1888.

.... IT is my opinion that, with our present knowledge of machinery, a steam engine can be built that will produce a horse-power with three-quarters of a pound of coal an hour, if of sufficient size to reduce the percentages of loss by radiation to a minimum.—*E. N. Dickerson.*

.... THE development of the electric service of a city can not be accomplished without the co-operation of the corporation with its citizens.—*A. R. Foote.*

.... THE problem of the steam engine is to convert the potentiality of combustion into dynamic energy; and that steam engine is the best which can obtain the most power from the least coal.—*E. N. Dickerson.*

.... THE uses of electricity are limited only by the want of intelligence in producing fitting apparatus for its application. The demand for such apparatus is limited only by the want of intelligence on the part of the public to know how to use it properly.—*A. R. Foote.*

NEWSPAPER ELECTRICITY.

The rapid spreading of the technics of electric lighting is said to be devoid of a natural basis as long as there is no theoretical and practical soundness in the construction of dynamos.—N. Y. *Times.*

Indicators worked by electricity to prevent spontaneous combustion are being quite generally used on shipboard.

The skin is generally high resisting, while the conductibility of the bones is less than two-fifths of the other hypodermic tissues.

The coefficients used for the reduction of dielectric resistance do not progress arithmetically, but follow the laws of compound interest.

As far as can be seen, the only thing likely to interfere with the successful working of subways for electric wires would be an unexpected and rapid deterioration of the lead covering to the cables.

A strong blowpipe of oxhydrogen flame from one carbon to another sets up an E. M. F., which would fully account for the opposing E. M. F. of the arc.—N. Y. *Commercial Advertiser.*

THE PROPOSED BERMUDA-HALIFAX CABLE.—ITS USEFULNESS FOR WEATHER PREDICTIONS.

The announcement made on Thursday, March 21, by the British post-master general, that the government intended to lay a submarine cable between Bermuda and Halifax, will be good news to all Atlantic seamen and all American and European meteorologists.

Bermuda is a natural observatory for watching hurricanes emerging from the tropical ocean and threatening to assail the United States, or to advance northeast wardly from the Gulf Stream into the transatlantic steamer tracks, and subsequently to burst upon the shores of Europe. Of course an observer at Bermuda cannot see with the naked eye what a Gulf Stream storm is doing, or determine by ocular demonstration what its course will be. But by watching the fluctuations of the barometer at this mid-Atlantic station and by reporting them by cable to America and Europe, meteorologists on either continent will be enabled to feel the pulse of the storm, and to determine more accurately its intensity and its future movements. For purposes of weather and storm forecasting in our Atlantic states, therefore, weather cablegrams from Bermuda will be invaluable.

But if the interests of Atlantic navigation be consulted maritime nations should co-operate in an attempt to form a net-work of ocean weather observations both to the northwest and southwest of Bermuda. From Bermuda to Halifax is 750 nautical miles. This requires quite a long stretch of cable. A floating observatory could be anchored on the southeastern side of the Great Newfoundland Bank in 30 fathoms of water, and connected with the telegraph system at Cape Race by a cable only 200 miles long. With a telegraph station on the Great Bank—very near the main transatlantic tracks of steamers—it would be easy to obtain intelligence of the movements of Atlantic storms on both sides of the ocean. Moreover, all vessels crossing the Atlantic could be warned from such an observatory of the progress of dangerous storms and the movements of ice fields and icebergs in the main highways of ocean commerce.

The time is ripe for some international effort to be made to secure to the merchant marine the advantages of storm and ice warnings, which can only be done by the establisment of mid-ocean observatories. It is to be earnestly hoped that the International Marine Conference, which meets at Washington this year, will take up this subject.—*New York Herald.*

THE BELL TELEPHONE COMPANY'S ANNUAL MEETING.

The annual meeting of the American Bell Telephone Co. was held March 26. While the balloting for directors and other officers was in progress the annual report was read. It says:—

"Your directors, believing that part of the income from royalties should be treated as capital, have transferred $600,000 from the net surplus for the year to a reserve account. The company earned in the year 24.45 per cent. on the stock, and has assets of $258 per share. The long-distance service has been extended from Albany to Buffalo and new lines have been built from Chicago to Milwaukee, and from Boston to Providence. Additional pole line has been built from New Haven to New York. About $2,200,000 has been spent on long-distance lines, which now comprise about 26,083 miles of wire.

"The gross earnings of the year were $3,865,118; expenses, $1,450.913; net earnings, $2,414,205; total dividends, $1,789,878. Deducting a reserve for general depreciation, the surplus account remains the same as last year—$2,028,085. The number of exchanges is 742, an increase of three; branch offices, 452—no increase; miles of wire, 170,471—increase, 24,083; subscribers, 171,454—increase, 12,742; instruments under rental, 411,511—

it is contended that the patentee did not intend to limit the invention to the oxides or salts of lead not soluble in the battery fluid, but wished to include generally all substances as materials for covering the supports which are capable of absorbing or storing electricity, electrolytically. The patentee specifically states that the invention includes manganese. A support would be within the invention, therefore, if coated with the sulphate of manganese, which is a salt soluble in the liquid, though the oxide of its base is insoluble.

It is thought, then, that the language of the patent, although by no means clear, can hardly be construed to exclude a coating soluble in the electrolyte. Why the patentee, having invented a practical, efficacious and meritorious method, should have used language which apparently includes an inferior and comparatively useless one is, indeed, inexplicable. That it was intentional can hardly be imagined. If these conclusions are correct it follows that the claim should be construed to cover—

First.—A secondary battery as distinguished from a primary battery.

Second.—An (one) electrode in the battery capable, in conjunction with the other electrode, of receiving and discharging electricity as described

Third.—The said electrode formed of a plate of metal or carbon or any suitable non-metallic substance.

Fourth.—The active layer of sufficient depth and uniformity to operate successfully added to the plate in any suitable way as a paint, paste or cement, or electrolytically or chemically.

Fifth.—The active layer of spongy lead or any metallic compound capable of satisfying the conditions of the patent as to porosity, etc.

Sixth.—Any suitable electrolytic liquid.

The Court then takes up the question of anticipation together with the enquiry whether the real invention of Faure can be saved by a disclaimer of non-essential features inadvertently inserted in the specification.

Full discussion is given to exhibits and testimony introduced by the defendants to show anticipation and lack of patentable novelty, comprising publications, patents, and oral evidence, extending from De la Rive's use of peroxide of lead; the platinum plate secondary battery described in the Smithsonian Institution's report for 1856, to the experiments of Mr. C. F. Brush, in 1879, and subsequently. In none of the publications or testimony does the Court find satisfactory evidence of an anticipation of the real invention described in Faure's specification, viz., the application of the active material in the form of a paint, paste or cement.

Discussing the evidence of prior invention by Charles F. Brush, Judge Coxe says:—

In determining this question, Faure, being at that time a citizen of France, is not permitted to claim the invention earlier than the date of his French patent, which was October 20, 1880, and possibly not earlier than December 7, 1880, which is the date of the decree (*arrête*) under which it was delivered. * * * *

Mr. Brush testifies that in the latter part of 1878 he first became familiar with the discoveries of Planté, and learned that the lead plates constructed by him required several months of electrical treatment in order to produce the necessary active coatings on their surfaces. In December, 1878, or very early in 1879, he conceived the idea of making a secondary battery by applying mechanically to suitable plates an active or absorbing coating so that such plates might be used at once, after suitable charging, for electrical storage purposes without the tedious, preliminary forming process described by Planté. In the summer of 1879 he embodied this idea, making a secondary battery by applying to suitable plates or supports, by mechanical means, an active or absorbent coating. For this purpose he took a piece of sheet lead about three inches wide and about twelve inches long and sprinkled thereon finely divided metallic lead, in the form of a fine powder, which could be passed through a sieve. This layer was about one-sixteenth of an inch in thickness and it extended the whole width of the plate and about three-fourths of its length. The lead powder was held in place by blotting paper, the edges of which were turned back and under the plate at the sides and bottom. A narrow strip of wood was laid longitudinally on the blotting paper, and the whole was wound tightly with a string. This plate was suspended in a tall glass jar, nearly filled with dilute sulphuric acid, and formed the oxygen element of the cell. The hydrogen element was a plate of amalgamated zinc suspended opposite the prepared lead plate in the glass jar. Soon after the completion of this cell he prepared two more lead plates in exactly the same manner as the one described, and hung them both in a tall glass jar filled with the same electrolyte. In this cell one of the prepared lead plates formed the oxygen element and the other the hydrogen element. He connected this cell in a series with the one first described and charged it by means of the current from a dynamo-electric machine. The strength of the current was not measured, but it was somewhere about five amperes. He charged the cell several hours on each of several days before commencing to discharge it. He discharged it through a fixed and constant resistance and noted the time which the current lasted and was thus able to compare the performance of this cell quantitatively with that of other cells discharging through the same resistance. This resistance consisted in the helices of the electro-magnet of a single stroke electric call bell. Upon the passage through this magnet of the current from the secondary battery cells its armature was strongly attracted. He found that the electrical storing capacity of the prepared plates was very much greater than that of the Planté plates of the same size. During the first few weeks, after the construction of the cell with the lead plates as described, he discharged and re-charged it frequently, and sometimes daily. After that he always kept it charged, and discharged it less frequently up to May 1880. * * * * About the same time he made two other cells alike in every particular, except that the coating was, in one instance of red oxide of lead and in the other of litharge. He subjected these cells to the same treatment as the ones first described with substantially the same result. He says of these cells that "they were all completed, finished and operative storage batteries from the time of their construction and first charging up to the time of the fire when they were destroyed. They all operated successfully and reliably during that time."

All of the results obtained by Mr. Brush were carefully noted down and preserved, some in the form of entries in a diary and some on loose sheets of paper. On the 6th of May, 1880, his laboratory with its contents were totally destroyed by fire. His diary and the loose memoranda concerning his experiments were all lost.

The Court here recites from Mr. Brush's testimony further statements describing storage batteries constructed by him after the fire of May, 1880, including grooved lead plates, some having the grooves filled with yellow oxide of lead, and some with sulphate of lead.

After the fire in 1880 a full memorandum was kept of the experiments and results obtained. After Faure's patent was issued in January 1882, interferences were demanded by Brush and resulted in decisions in his favor at all stages during the progress through the Patent Office.

In many important features of his testimony he is corroborated by the evidence of three witnesses who were present and saw many of the experiments referred to. After the fire Brush undertook to reproduce from memory the memoranda which had been destroyed, and criticism is made that he does not describe with particularity the batteries which he now says he invented, though he does describe with great detail other and inconsequential experiments. It is unfortunate that his reproduced notes should be so meagre on the points in controversy, that his original apparatus should have been destroyed and that his battery of July, 1880, should have been lost. Improbabilities and inconsistencies in his statements are pointed out, and it is asserted that none of the experiments detailed by him amount to a perfected invention. Although it is unquestionably true that this proof might have been more convincing and satisfactory it is also true that there is nothing opposed to it but presumption conjecture and guesswork based upon its inherent defects. There is no fatal improbability, as in the case of the other alleged prior inventor, and the Court would not be justified in rejecting, for the reasons suggested, the testimony of four intelligent, respectable and apparently fair and honest witnesses. The testimony of Mr. Edmunds and Mr. Hayes is not inconsistent with the statements of Mr. Brush. It is not surprising that he did not care to disclose his experiments to Mr. Edmunds, and when they met and conversed in Paris his application was on file in the Patent Office. Nor does it avail the complainant that the Brush structures were experimental as distinguished from commercial batteries. If the invention was made it cannot matter how it was made or for what purpose. It is only where experiments fail to reach the desired result, and are abandoned as failures, that they are rejected as proof of want of novelty. They are not rejected when they are carried to successful consummation.

Waterman *vs.* Thomson, 2 Fish., 461.
Aiken *vs.* Dolan, 3 Fish., 197,203.
Walker on Patents, Secs. 63, 86.

The evidence of Mr. Brush as to what he accomplished in 1879 and 1880 must be accepted as true, and although Faure was *de facto* the first inventor Brush was *de jure* the first inventor of the electrodes described by him. It is not, however, contended for Mr. Brush that he applied the active layer to any of his electrodes in the form of a paint, paste or cement.

It, therefore, becomes apparent that the combination of the first claim, construed as it must be construed under the loose and inaccurate language of the specification, is anticipated in every form in which the active layer can be applied, save one, namely, in the form of a paint, paste or cement. The question now to be considered is, can the patent be saved to this extent? The application in the form of a paint, paste or cement was the real invention which Faure made. It was in this form that he gave it practical embodiment, it was this that the scientific world under-

stood to be his improvement. An electrode for a secondary battery with the active layer applied in this form has many undoubted advantages over an electrode otherwise coated. It can be applied more evenly; it more readily adheres to the support; it does not shift its position, it "will also pack more closely and readily and make an adherent layer from which air can be thoroughly excluded so that uniform contact with the plate and throughout the mass of applied material is secured," and, finally, a greater and less expensive storage capacity can be obtained.

There can be little question, upon this proof, that Faure made his discovery as early as August, 1878. Scientific people at once recognized the progressive step taken, and to him was accorded the credit of an invention of extraordinary merit.

Sir William Thomson says: "I knew the Planté secondary battery prior to 1880. Faure's invention was a very great improvement on it, so great as to produce a valuable apparatus for a large practical work instead of merely an interesting and instructive scientific instrument, which Planté's secondary battery was."

It does not appear that Sir William Thomson had the Faure patent before him but he considered that "Faure's invention was the application to two plates—preferably lead plates—of a thin layer to oxide of lead mechanically applied prior to placing the plates in the battery fluid, the plates and their coatings being insoluble in the battery fluid, and the coatings becoming so altered by the charging current as to become capable of yielding a reverse current, and this over and over again an indefinite number of times. I consider the novelty of Faure's invention to be the application of the oxide of lead to the lead plates before passing an electric current through them and the rendering of these coatings active by immersing them in the battery liquid and passing the charging current through them."

The Court here quotes from the testimony of the experts of both the complainants and defendants to much the same purport as the above, and continues:—

The inventor himself says of his earliest experiments:—"I took two plates of lead about two and a half inches wide, covered each plate on one side with a paste of litharge, etc. * * * * I do not claim to have invented spongy lead, but I boast of being the first that produced it in large quantity on the electrode of a battery, and the first to recognize it as an efficient element of a secondary battery."

It is, then, established with reasonable certainty that the discovery of a mechanically applied layer of lead, or like substance, insoluble in the electrolyte and placed upon the supports in the form of a paste, paint, or cement prior to their immersion in the battery fluid, so as instantly to become porous and capable of receiving and discharging electricity, was one of great merit. There is no doubt either that Faure was the first to make this discovery. Can he hold the fruits of his genius, or must the Court decide that in attempting, through mistake or ignorance of what had previously been accomplished, to grasp more than he was fairly entitled to he has lost what actually belonged to him? Believing that Faure is an inventor of more than usual merit, it can readily be inferred that the Court enters upon this inquiry with every disposition to give him the benefit of his actual invention, if possible to do so under the law.

The proof establishes two propositions with equal clearness. First, Faure was the inventor of a secondary battery electrode coated in the manner stated; and, second, he was not the inventor of an electrode otherwise coated.

If, by means of a disclaimer, the patent can be restricted to the actual invention this course should, in fairness, be adopted.

Section 4,922 of the Revised Statutes provides that—

Whenever, through inadvertence, accident or mistake and without any willful default or intent to defraud or mislead the public, a patentee has, in his specification, claimed to be the original and first inventor or discoverer of any material or substantial part of the thing patented, of which he was not the original and first inventor or discoverer, every such patentee, his executors, * * * * and assigns * * * * may maintain a suit at law or in equity, for the infringement of any part thereof, which was *bona fide* his own, if it is a material and substantial part of the thing patented and definitely distinguished from the parts claimed without right, notwithstanding the specifications may embrace more than that of which the patentee was the first inventor or discoverer. But in every case in which a judgment or decree shall be rendered for the plaintiff no costs shall be recovered unless the proper disclaimer has been entered at the Patent Office before the commencement of the suit. But no patentee shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer.

Section 4,917 provides as follows:—

Whenever, through inadvertence, accident or mistake, and without any fraudulent or deceptive intention, a patentee has claimed more than that of which he was the original or first inventor or discoverer, his patent shall be valid for all that part which is truly and justly his own, provided the same is a material or substantial part of the thing patented, and any such patentee, his heirs or assigns, * * * * may on payment of the fee required by law make disclaimer of such parts of the thing patented as he shall not choose to claim or to hold by virtue of the patent or assignment, stating therein the extent of his interests in such patent. Such disclaimer shall be in writing, * * * * and it shall thereafter be considered as part of the original specification. * * * * But no such disclaimer shall affect any action pending at the time of its being filed, except so far as may relate to the question of unreasonable neglect or delay in filing it.

Mr. Walker, in his work on patents, at Sec. 193, has blended these two sections in one comprehensive and perspicuous explanation. He says (Sec. 194 *et seq.*): "The primary fact which brings the law into play is the claiming by a patentee of materially more than that of which he was the first inventor. Such errors may spring from inadvertence. That is to say, they may spring from failure on the part of the writer of the claims to exercise proper care in penning them. So, also, they may arise from accident, from chances against which even diligent care cannot always guard. But mistake is the most common source of such errors, and such errors may arise from mistake of fact or from mistake of law. * * * * If the patentee is willing to eliminate from his claims, everything which later information shows had been invented before him, he ought to be allowed to retain his exclusive right to the residue. * * * * There are cases where two or more inventions are covered by one claim, and in such cases a disclaimer may be made to expunge one of those inventions from that claim without disturbing the others."

Mr. Curtis says: "Specifications may also be amended by another process, that of filing a disclaimer, whenever, through inadvertency, accident or mistake the original claim was too broad, claiming more than that of which the patentee was the original or first inventor, provided some material and substantial part of the thing patented is justly and truly his own. * * * * In Seed *vs.* Higgins (8 Ell. & Blackf., 755, 771) the patentee * * * * entered a disclaimer, declaring 'For the reasons aforesaid, I do hereby disclaim all application of the law or principle of centrifugal force as being part of my invention or comprised in my claim, except only the application of centrifugal force by means of a weight acting upon a presser, so as to cause it to press against the bobbin, as described in said specification.' It was held by the Court of Queen's Bench, and affirmed by the Exchequer Chamber, that this disclaimer was valid, and that the general specification being read in connection with it, the result was a claim for only the machine particularly described." (Curtis on Patents, Secs. 286, 287.)

Judge Coxe cites the following cases:—

Aiken *vs.* Dolan, 3 Fish, 197.
Meyers *vs.* Frame, 8 Blatchf., 446.
Taylor *vs.* Archer, 8 Blatchf., 315.

(A disclaimer, filed *pendente lite* of part of the claim, was held to be valid.)

Tuck *vs.* Bramhill, 6 Blatchf., 95.
Schillinger *vs.* Gunther, 17 Blatchf., 66.
Roemer *vs.* Newman, 26 Fed. Rep., 102.

Dunbar *vs.* Meyers, 94 U. S., 187.
Union Met. Cat. Co. *vs.* U. S. Cat. Co., 112 U. S., 624.

The law, as established by the foregoing authorities, permits the complainant to save what was really Faure's invention. The defendants, in opposition to this view, rely upon Hailes *vs.* Albany Stove Co., 16 Fed. Rep., 242, affirmed 123 U. S., 582.

There seems to be a clear distinction between that case and the one at bar. In that case there was nothing in the specification to indicate to the public that the invention of the patentee was what he sought to make it by the disclaimer. He claimed "a perforated fire pot," etc., and when he found that this was old he sought by disclaimer to limit his invention to a particular kind of fire pot described for the first time in the disclaimer. At page 587 the Supreme Court say: "A disclaimer is usually and properly employed for the surrender of a separate claim in a patent, or some other distinct and separable matter, which can be excinded without mutilating or changing what is left standing. Perhaps it may be used to limit a claim to a particular class of objects, or even to change the form of a claim which is too broad in its terms, but certainly it cannot be used to change the character of the invention. And if it requires an amended specification or supplemental description to make an altered claim intelligible or relevant, while it may possibly present a case for a surrender and reissue, it is clearly not adapted to a disclaimer. A man cannot, by merely filing a paper drawn up by his solicitor, make to himself a new patent, or one for a different invention from that which he has described in his specification. That is what has been attempted in this case. There is no word or hint in the patent that the invention claimed was a firepot with sides grated only half way, or part of the way, from the bottom towards the

top, or that such partially grated sides have any advantage over those grated all the way to the top. The first claim as modified by the disclaimer has nothing in the specification to stand upon, nothing to explain it, nothing to furnish a reason for it."

The decision states no new law, it is entirely in line with the other authorities cited. Instead of forbidding it would seem to sanction a disclaimer in the case at bar. The facts here and in the Hailes case are wholly different. Hardly one of the criticisms upon that disclaimer would apply to a properly drawn disclaimer here.

The part of the invention which, *bona fide*, belongs to Faure is an electrode in a secondary battery consisting of a support coated with an insoluble layer of active material in the form of a paint, paste or cement so as to be or become instantly spongy, etc. It was this that the scientific world recognized as a great discovery of great merit and importance. It was this that the distinguished Scotch electrician regarded as "marvelous." And this was the result of Faure's genius. No one anticipated him. It is honestly his. What he did not invent was an electrode in a secondary battery coated with a soluble layer of active material, neither did he invent an electrode on which the active material is applied by "galvanic action or chemical precipitation, or otherwise." The claim is broad enough to cover all these forms probably, and some of them certainly. What he is not fairly entitled to he wishes to give up, and keep what is certainly his own. He does not seek to broaden his patent, but greatly to restrict it. No one will infringe unless he constructs his battery in the one way to which the patent will be confined. This is the patentee's way, and it has many distinguishing characteristics which differentiate it from the ways pointed out by others. The matter to be relinquished is distinct and separate and can be exscinded without mutilating what is left. No amendment is necessary. The claim read in the light of the description is too broad. It is sought to limit it. The disclaimer suggested will not make a new patent or a different invention. The invention is fully described in the specification, and the limited claim will stand on that description.

After giving the subject the most careful consideration it is thought that Faure was the originator of the invention just described, and that it would be unjust to him to declare the patent wholly void if he is willing to restrict it to what is lawfully his own.

The fourth claim of the Faure patent (which the Court deems to be for a combination containing the following elements: *First*—A secondary battery; *Second*—A series of cells; *Third*—In each cell a pair of electrodes with an active spongy layer thereon; *Fourth*—Non-porous partitions between adjacent cells) is held not to bear a construction broad enough to cover the batteries of the defendant. In its broad sense the claim is held to be invalid for want of novelty. The mere adaptation of a well-known method of cell division to a storage battery is not regarded as an invention. In closing this part of the case Judge Coxe says:—

His invention was for a new electrode in a secondary battery. This he is entitled to, but he is not entitled to claim as new a well-known construction of cells because he puts his new electrodes into them. It is clear that a construction of the claim which is broad enough to cover the defendants' battery renders the claim invalid.

Bush *vs.* Fox, 28 Law and Eq. Rep. 1.
Holmes *vs.* The Electric Company, 33 Fed. Rep. 254.
Hailes *vs.* Stove Co., 123 U. S. 586.
Heating Co. *vs.* Burtis, 121 U. S. 296.
Railroad *vs.* Truck Co., 110 U. S. 490.
Boudoir Car Co. *vs.* Monarch Car Co., 34 Fed. Rep. 130.

A limited construction can, however, be given the claim which will render it valid. The defendants' expert insists that the claim must be confined to a combination in which the electrodes are combined with non-porous partitions between adjacent cells by being applied thereto. The manner in which this is done is described in the specification. It says: "Figure 6 is cross-section of an electrode with non-porous partition, having the prepared plates secured on both sides, and adapted for use in a battery with series of adjacent cells. * * * * It shows the arrangement of parallel plates formed with an interposed wooden board, *x*. This arrangement permits of employing thin sheets of lead, while securing at the same time sufficient stiffness, and affording means of firmly securing the parts, *x*, without any leakage between the adjacent cells formed on each side of the leaden plate *a*." The specification further states that when the supporting plates are to be placed either parallel or in any other position permitting of their being distorted by mechanical strain, stiffness may be imparted by applying them on wood or hard rubber non-porous boards so as to prevent any liquid passing from one cell to another. The boards of these compound supports have edges fitted with India rubber in order to render the cells perfectly liquid tight.

It is argued with force and plausibility that it was the intention of the patentee, as shown by these extracts from the specification, to cover only his special construction, the novel feature of which is the non-porous partition with which the electrodes are combined and to which they are applied. It is asserted that this intention is rendered more certain by an examination of the file wrapper where it is still more clearly disclosed, and that nowhere in the specification is there a description of the apparatus as constructed by the defendants. In view of these facts and because the patentee, in effect, disclaimed the construction sought to be placed upon the claim by the complainant, it would seem that the defendants' construction has much in reason and authority to support it and is the more rational of the two.

So construed the defendants do not infringe the claim.

The patent granted to Joseph Wilson Swan, February 17, 1885, No. 312,599, is for an improvement in secondary batteries. The application was filed January 18, 1882. The object and aim of the patentee was the production of plates having surfaces more suitable for holding the active material. In carrying out this idea he prepares plates with perforations, cells or holes extending through the plates, in which the active material is packed. He says: "It should be understood that the form of the cells may be greatly varied without departing from the principle of my said invention, the object being to obtain an interstitial construction of plate capable of affording a very large amount of active surface in a small compass, and to prevent the coating of oxide or spongy lead from falling away from the plate, as it would from a plain vertical surface, unless held in position by some material external to the said coating."

The claim is:—

A perforated or cellular plate for secondary batteries having the perforations or cells extending through the plate and the active material, or material to become active, packed in the said perforations or cells, substantially as described.

The specification states that the patentee has obtained a patent in Great Britain for the same invention, dated May 24, 1881. It is argued that this allegation carried the invention back to the date of that patent although the patent itself has not been introduced in evidence. No authority is produced to sustain this contention. Being a mere declaration, unsupported by proof, it is thought that it cannot be accepted as the date of the invention, which, in the absence of other proof, must be taken as of the date of the application, January 18, 1882.

The court here quotes Sir Wm. Thomson and the experts on both sides, as to the value of perforated electrodes for storage batteries, and says:—

In view of these facts there is no difficulty in deciding that an electrode so constructed was patentable. The invention is a simple one, but something more than mechanical skill was required. * * * *

The question, therefore, is whether there is anything in the art prior to January 18th, 1882, which anticipates the claim or renders it invalid.

The English patent, granted to John S. Sellon, does not anticipate for the reason that though dated September 10th, 1881, it was not sealed until March 10th, 1882, after the filing of Swan's application. It was not made patent to the public, therefore, until March 10th, 1882.

Smith *vs.* Goodyear, 93 U. S., 486–498.
Bliss *vs.* Merrill, 33 Fed. Rep., 39, 40.
Siemens *vs.* Sellers, 123, U. S., 276–283.

But the evidence of Professor Asahel K. Eaton, if it does not amount to a complete anticipation, so narrows the field of invention that nothing remains of which to predicate patentable novelty. It is thought, however, that as to some of the electrodes made by him there can be no doubt that they fully anticipate Swan's claim. If made now for the first time they would infringe, being made before the application, they anticipate.

Cook *vs.* Sandusky Tool Co., 4 Sup. Ct. R., 4.
Peters *vs.* Active Mfg. Co., 21 Fed. Rep., 319; affirmed Sup. Ct., Mch. 5, 1889.

Professor Eaton testifies that in 1881, and certainly prior to August, 1881, he made experiments in secondary batteries using perforated lead plates for the electrodes. He finally adopted them, considering them preferable to others tried by him. These plates were perforated by means of a belt punch, which cut out small discs varying from a quarter to five-eighths of an inch, according to the size of the plates. Lead sponge previously prepared was then precipitated upon both sides of the plate so as to cover both surfaces and fill the perforations. He says: "I afterwards adopted one of the methods which I had tried where I used two perforated plates with the sponge deposited upon one or both of them and the two plates put together so as to retain the sponge between them, the sponge filling the perforations. This made one electrode. The other electrode was made with two similar perforated plates, the peroxide being made into a paste with sulphuric acid and water and pasted upon each side of a piece of asbestos. This was put between the two perforated plates and pressed down so that the paste covered the whole surface of each half plate and filled the perforations. Some of these plates were perforated so as to leave a burr projecting in one direction, which aided in the

retention of the paste, the two burred surfaces being outside. This provided an enlarged cellular cavity."

In July, 1881, he made another battery with the assistance of one George Farrington, who corroborates him in part as to its construction. This battery was made by spreading the described paste upon either cloth or asbestos and enclosing it between two perforated plates of lead. The perforations, in the absence of a proper tool, were made with a knife. This formed one element. The other element was made by precipitating lead sponge upon one surface of a similarly prepared plate and covering it with another plate, so as to make one, folded together at the edge. The paste was minium mixed with sulphuric acid and water. This paste filled the perforations in the plates.

Professor Eaton also made electrodes by coating with a similar paste a frame work of woven lead wire. The batteries thus constructed by him were charged and worked successfully. Besides Farrington he is corroborated by Mr. Sleeper, who assisted in the construction of the batteries of August 1881, by punching holes in regular order in the leaden plates. And Sleeper is, in turn, corroborated by entries made at the time in his diary, which also contains rough drawings of the perforated leaden plates. No evidence is offered by the complainant which at all conflicts with the verity of these statements. As before observed, the Court is not permitted to reject the evidence of unimpeached and respectable witnesses, when they are corroborated, and there is nothing to cast a doubt upon the truth of their statements. Upon this evidence, therefore, the first Swan patent must be declared invalid.

The second patent granted to Joseph Wilson Swan is dated May 26, 1885, No. 318,828. The application was filed May 3, 1883. The claim is as follows :—

"In a battery plate or electrode composed of a conducting support combined with active material, the support in the form of a plate with angular or equivalent holes, cells or perforations extending through the same, and separated from one another by webs, walls or partitions of uniform cross-section, the active material being placed in said holes, cells or perforations, substantially as set forth."

This would seem to be for the same subject-matter covered by the first patent of Swan. It is conceded that the alleged invention is described and shown in the first patent. The only difference suggested is that the second patent is for a more limited sub-division of the same general invention. The patent in the specification states :—

"It should be observed that I do not claim herein, broadly the use of plates provided with holes or perforations extending through the same, and having the active material, or material to become active, held in such holes or perforations, as this forms the subject-matter of patent granted to me on the 17th day of February, 1885, numbered 312,599."

One of the complainants' experts after stating his understanding of the first patent says of the patent in hand : "It has a specific claim, a claim rendered specific by its limitation to uniform webs, walls or partitions separating the perforations from each other." Another of the complainants' experts says that his understanding is that the second patent covers plates or electrodes such as are described in the first patent, "with the additional limitation that the webs, walls or partitions between the cells shall be of substantially uniform cross-section."

It will be observed that the drawing of the first patent shows a plate made in exact accordance with this limitation, and the specification states that the form of the cells may be greatly varied without departing from the principle of the invention. Even if the second patent can be distinguished from the first in the particular stated by the experts it is entirely clear that the difference pointed out is wholly insufficient to sustain invention. After the first patent there was absolutely no room for the second patent ; which, upon the most favorable construction for the complaint, simply claims an arrangement which any one who had sense enough to make the perforations at all would most certainly adopt. When a patent has been granted for a plate containing rows of holes another patent cannot be granted for the same plate containing *uniform* rows of holes. Neither can there be anything patentable in the mere shape of the holes. A patent for a device containing round holes will preclude a subsequent patent for the same device with square or triangular holes. Bung Mf'g Co. *vs*, Bung & B. Co., 31 Fed. Rep., 76, 79.

Especially is this so when the applicant is confronted with his own express declarations that the shape is wholly immaterial.

It is not necessary to consider whether a valid patent can be obtained for an invention described, but not claimed, by the applicant, in a prior patent issued to him ; the application for the second patent being filed before the first patent issues. That is not this case. Swan describes no invention in the first patent which is not covered by the claim of that patent. What is not claimed is not patentable.

It follows, therefore, that the complainant, upon filing a disclaimer, limiting the first claim of the Faure patent to an electrode of a secondary battery to which the active layer is applied in the form of a paint, paste or cement, insoluble in the electrolytic liquid, is entitled to a decree for an injunction and an accounting upon the claim as thus limited, but without costs.

ANNULMENT OF THE EDISON LAMP PATENT IN CANADA.

DECISION FILED FEBY. 26, 1889.

Before the Deputy Commissioner of Patents.

The Royal Electric Co., of Canada, petitioners, and Edison Electric Light Co., respondents.

Messieurs Lash, Q. C., of Toronto ; McGibbon, of Montreal ; Curtis, of New York ; and Kerr, of Pittsburgh, Pa., counsel for petitioners.

Messieurs Hector Cameron, Q. C., of Toronto ; MacMaster, Q. C., of Montreal ; and Dyer, of New York, counsel for respondents.

ABSTRACT.

This is a Petition to the Minister of Agriculture, bearing date May 1, 1888, to have declared null and void the patent No. 10,654, granted to Thomas Alva Edison, on Nov. 17, 1879, "for new and useful improvements on electric lamps, and in the method of manufacturing the same, the title whereof is *Edison Electric Lamp*," on the ground of violation of *The Patent Act*, Consolidated Statutes of Canada, Chapter 61, Sec. 37.* On Nov. 16, 1881, an extension of three months' time within which to manufacture was granted to the patentee, on his application to this effect, in which he alleged that, "having been engaged in introducing his invention in other countries, he had failed in manufacturing in Canada, within the two years prescribed by law, owing to the large capital which is necessary to establish such manufacture."

By assignment the respondents became the holders of the patent.

The petition alleged that the patentee and his assignees had not manufactured the invention within the two years prescribed by law, and that the alleged extension of three months within which to do so had been obtained by false and willful misrepresentation ; that the patentee and his assignees had imported the invention into Canada after the twelve months allowed by law, and prayed, for these reasons, that the patent be declared null and void, and the extension above mentioned set aside and canceled.

On the application of the petitioners, the Deputy Commissioner issued an order upon the respondents' counsel to produce at the trial all the invoices, accounts, letters and other documents, enumerated in a certain paper, or "Notice to produce," previously served upon them, at the instance of the petitioners, in order that the same might be used as evidence if required.

By mutual consent, the trial was fixed for Nov. 13, when the respective counsel, with the witnesses being present, the case was proceeded with.

The respondents' counsel, in addition to the general denial, by way of preliminary plea, took exception to the jurisdiction of this tribunal, on the ground, that on March 31 last, and prior to the date of this petition, the respondents had taken action against the petitioners, in the Superior Court for Lower Canada, at Montreal, praying for damages, and the issue of an injunction, for infringement of the patent now in question ; that the petitioners did not answer the action, but on May 18, applied for a stay of proceedings in the action, until the decision on this petition could be obtained, and which application the court had granted.

The Commissioner here recounts the arguments presented on the question of jurisdiction, including citations and references, to sections 33 and 37 of the Patent Act, and a number of precedents, viz., The Bell Telephone Cases ; Smith *vs.* Goldie, Supreme Court Reports, vol. 9, p. 46 ; Mitchell *vs.* The Hancock Inspirator Co., and others.

The Deputy Commissioner stated, that in view of the large number of witnesses present from the United States, and other

*SEC. 37. Every patent granted, under this Act, shall be subject and be expressed to be subject to the condition that such patent and all the rights and privileges thereby granted shall cease and determine, and that the patent shall be null and void at the end of two years from the date thereof, unless the patentee or his legal representatives, within that period, commence, and, after such commencement, continuously carry on in Canada the construction or manufacture of the invention patented, in such manner that any person desiring to use it may obtain it, or cause it to be made for him, at a reasonable price, at some manufactory or establishment for making or constructing it in Canada,—and that such patent shall be void if, after the expiration of twelve months from the granting thereof, the patentee or his legal representatives or his assignee for the whole or a part of his interest in the patent, imports or causes to be imported into Canada, the invention for which the patent is granted ; and if any dispute arises as to whether a patent has or has not become null and void under the provisions of this section, such dispute shall be decided by the Minister or the deputy of the Minister of Agriculture, whose decision in the matter shall be final.

2. Whenever a patentee has been unable to carry on the construction or manufacture of his invention within the two years hereinbefore mentioned, the commissioner may, at any time not more than three months before the expiration of that term, grant to the patentee an extension of the term of two years on his proving to the satisfaction of the commissioner that he was, for reasons beyond his control, prevented from complying with the above condition.

3. The commissioner may grant to the patentee, or to his legal representatives or assignee for the whole or any part of the patent, an extension for a further term not exceeding one year, beyond the twelve months limited by this section, during which he may import or cause to be imported into Canada the invention for which the patent is granted, if the patentee or his legal representatives, or assignee for the whole or any part of the patent, show cause satisfactory to the commissioner, to warrant the granting of such extension ; but no extension shall be granted unless application is made to the commissioner at some time within three months before the expiring of the twelve months aforesaid, or of any extension thereof.

places distant from Ottawa, who were naturally anxious to return to their homes as soon as possible, he would not delay the proceedings at this stage, but would render his decision on this point, when judgment should be rendered on the merits of the case.

The evidence was then proceeded with, lasting over three days, including an admission of facts by the parties, when the case, by agreement, was postponed to the 17th December, for argument of counsel, when the case was ably argued, at great length, by counsel on both sides.

The evidence adduced by the petitioners established in substance: That the patent was granted to Thomas A. Edison on the 17th November, 1879; that on the 16th November, 1881, an extension of three months' time within which to manufacture was granted; that on the 12th February, 1880, Edison assigned the patent to "The Edison Electric Light Co.," and on the 30th December, 1886, the latter assigned to "The Edison Electric Light Co."—the respondents. The lamp consists of a glass globe or bulb, glass tubing, inside pieces of glass, platinum and copper wires, carbon filament and brass bottoms; all these articles were imported from the United States, from the time the patentee and his assignees began to make the lamps in Canada, and still continue to be imported; that the process of making the lamp from these imported articles consisted of several operations, such as attaching the carbon filaments to the leading-in wires—the leading-in wires having been previously let into the glass and sealed in; the glass bulb and tube attached to it, the air exhausted from the bulb, and connection made with the brass cap or base to attach it to the socket, to connect with the circuit, supplying the electric current. On the 14th November, 1881, The *Edison Electric Light Co.* started a small factory in Montreal, worked by two men, and the outfit consisted of a small dynamo, several pumps for producing the vacuum in the globes, several small glass blowers' fires, gas fires, altogether of the value of about $2,000, and commenced the manufacture of the lamps from the materials imported from the United States as above stated: and on the 17th had completed two lamps; the carbon filaments were put into the lamps in the condition they were brought in from the United States, and were not subjected to any further treatment or process of carbonization after their arrival in the factory in Montreal. The carbon filaments are made of bamboo, imported into the United States from Japan, in the crude or natural state, in strips, and on arrival at the factory in the United States, they are further split into smaller strips, the pith removed, and then by knives or dies, further reduced to the proper size of the filament; these filaments were then put on a block or mould packed with carbon, then put into a furnace and baked or carbonized; this process requires great skill and labor, and is very difficult, and can only be done by skilled workmen; they tried to carbonize the filaments in Montreal, but could not succeed, as the men were not skilled in the work. The glass bulbs were made in the United States from pot glass, the glass blowers there blowing them by several processes into the size and shape required. These bulbs were made expressly for use on the incandescent lamps, and must have the same expansion as the platinum, and are not ordinary articles of commerce; the glass tubing also must be made from the same quality of pot glass as the bulbs, so as to have the same expansion; the platinum wire also was specially prepared in the United States for use in the lamps. The employés were instructed not to sell the lamps to any who did not use the Edison dynamos or plant, and they accordingly did not so sell them, and refused to sell to any not using the Edison plant; that it was the policy of the company to do this, as the sale of the plant was more profitable than the sale of the lamps, the proportion being that where 800 lights were installed the total price was $12,000, while the cost of the lamps at $1 each was only $800, and this had practically the effect of creating a monopoly for the Edison plant. The first sale of lamps in Canada was made to the *Canada Cotton Co.*, at Montreal, in December, 1882. The capital stock of "*The Edison Electric Light Co.*," in November, 1881, was $720.000 or $780,000, the par value of the shares being $100, but they were then quoted and selling at from $1,000 to $1,200 per share, or a premium of $1,000 to $1,100 above par. In January, 1883, the factory in Montreal was closed, and the business transferred to Hamilton, and there increased and more men employed, but there was no change in the manner of getting out the lamps; the same articles were imported, but in larger quantities, the same steps of assembling all the parts and putting them together to complete the lamp were gone through at Hamilton, as in Montreal; at this time there were 3,800 lamps in use in Canada, and the annual output was from 8,000 to 10,000 lamps, and was gradually increasing; the proportionate cost of labor bestowed in the United States on the articles sent into Canada, to be used in the making of the lamps, is $32.50 on every 100 lamps made; while the proportion of the cost of labor bestowed on the lamps in Canada, after the importation of the articles composing it, is $21.80 per $100 worth of lamps made.

The respondents admitted the importation of the glass bulbs, the glass tubing, the platinum and copper wires, and the carbon filament, and that the importation continues still, and the evidence they adduced went to show that these were all raw material; that they were all ordinary articles of commerce, and could be used for any other purpose besides incandescent lamps; that the carbon filaments, as imported, were only partly manufactured in the United States, and the carbonization was completed in the Canadian factory, by the passing of an electric current through them while a high vacuum was maintained in the lamp bulbs, thereby reducing them to a pure carbon, and that this process of final carbonization was necessary to make a serviceable commercial lamp; that the glass bulbs and tubes, after they were imported, passed through several processes in the factory in Canada, to render them fit for use in the lamp; that the platinum was obtained in the United States, and before being sent into Canada for use in the lamps, was re-melted from the crude material, and then drawn out into wire, and slightly alloyed with iridium, so as to make it a little harder; and the wire was attached to the carbon and fitted into the glass bulbs in Canada; that if the company had been compelled to manufacture the carbons in Canada, it would have ruined the business in Canada; that the platinum wire would have cost two hundred fold more in Canada, as it requires a special furnace to prepare it; that the cost of material in the United States, as imported into Canada, would be in the proportion of one-third, and the labor in Canada, two-thirds.

Counsel for the petitioners argued that the evidence clearly showed that the patentee and his assignees had not complied with the provisions of *The Patent Act;* that they did not commence or carry on in Canada the manufacture of the invention within the time prescribed by law, and that they had imported it after the time allowed by law, and in addition thereto had refused to sell the invention as they were bound by law to do; that they showed bad faith and no intention to comply with the law from the beginning, as they only started their factory and began making the lamps on the 14th November, 1881, a few days only before the limit prescribed by *The Patent Act;* then again it is proved that at this period, when they applied for and obtained an extension of time, within which to manufacture, on the ground or pretension of the large capital necessary to carry on the manufacture, the capital stock of the Edison Electric Light Co, the then holders of the patent, amounted to over $700,000, the par value of the shares being $100, and their market or selling price was quoted in the newspapers at $1,000 or $1,200, or a premium of from $1,000 to $1,100 above par, while it is proved that the whole capital or plant they had in Canada at this time was only $2,000; this showed their utter want of good faith, and the misrepresentation amounting to fraud, practiced upon the Minister of Agriculture, to obtain an extension of time; that they refused to sell their lamps unless in connection with their plant, thus creating a monopoly for their dynamos or plant, which they had no right to do by law, which does not authorize or justify the imposing of conditions or restrictions upon the purchaser, as to the use of the invention when purchased by him; that the subsequent process of carbonizing the filament, after it was put into the globe and subjected to the passage of an electric current while a high vacuum was maintained, was no part of the patent, and could not be claimed for it; that the labor expended in the United States upon the articles before they were imported into Canada amounted, on the 66,500 lamps proved to have been made up to the present time, according to the proportions of cost proved, would amount to $30,000, which was so much loss to the Canadian laborer; and the manufacture of those lamps was increasing from year to year.

For the respondents it was contended that the patentee and his assignees had in every respect complied with the terms of *The Patent Act;* that they had commenced the manufacture within the time prescribed by the act, and had only imported the component parts of the lamp in the raw state or as raw material and ordinary articles of commerce; that there was no absolute proof that they had refused to sell except in connection with the Edison plant, and even if this were proved, it was no violation of the act, as the law did not, and could not, reasonably be construed to compel them to sell their lamps to opposition companies, who would run them on the arc or other plant not suited to the Edison incandescent lamp, and thereby injure or destroy the reputation of the lamp; they were always willing and ready to sell to those who would do justice to the lamp, and act fairly and honestly in giving it a fair trial; with regard to importation, it is proved that the glass globes and carbon filaments could not be made in Canada, and even if they could be made it would be at such a ruinous cost and expense that the business of manufacturing the lamps in Canada would have to be abandoned; that the law did not contemplate any such unreasonable and unjust condition as this; that in any case the importation of these articles was a small matter in comparison with the cost of labor expended on the manufacture of the lamps in Canada; that, moreover, they were merely ordinary articles of commerce, and not the invention or subject of the patent; that in two cases recently decided in the Supreme Court, and not yet reported, the *Ayer* case and the *Grinnell* case, in which the defendants were sued under the *Customs Act,* on the ground that they imported certain ingredients or articles, and afterwards assembled or put them together and manufactured an article upon which a higher duty was payable, the Custom authorities claiming that they were liable for the higher duty, the Supreme Court decided that the articles or ingredients were what they were when they crossed the boundary

line, and were not liable for the higher duty on the article into which they were manufactured after their entry into Canada; that the imported articles in the present case, could not be held to be the invention patented, and the patent could not, therefore, be declared void for contravention of *The Patent Act*.

The preliminary plea of the respondents again raises the question of the jurisdiction of this tribunal, on the ground that, by the 33d and 37th sections of *The Patent Act*, above quoted, the ordinary courts of justice have concurrent jurisdiction with the Minister of Agriculture, and the Superior Court for Lower Canada, at Montreal, having been first seized of the matter in dispute between the parties here, the petition should not and could not be entertained, the Superior Court, in which the proceedings originated, being the proper tribunal to adjudicate therein. Upon reading these two sections of the act concurrently, the meaning and intention of the law seem plain, consistent and comprehensible, and admit of the sole interpretation and conclusion, that in an action at law for infringement of a patent, the defendant may plead in defense, any fact or default which may render the patent void, and if the defense invoke the invalidity of a patent on the ground of illegal importation or non-manufacture, this must be done by pleading the only fact which, by the 37th section, establishes it—the decision of the arbiter therein specified, the Minister of Agriculture or his deputy, whose decision being final, no other tribunal can establish such fact or default. This view was held by Dr. Taché in the decisions rendered by him, and referred to at the argument, and in which he declared the jurisdiction of the Minister of Agriculture in this matter to be exclusive, and this view or finding has been sustained by all the judicial tribunals that have had occasion to refer to it. In the case of Smith *vs.* Goldie in the *Supreme Court*, the summary at the head of the report, if not to be considered as of the substance and part of the report, must assuredly be accepted as a correct and accurate interpretation thereof, contains the following words in paragraph 3: "The Minister of Agriculture or his deputy, has exclusive jurisdiction over questions of forfeiture under the 28th (now 37th) section of *The Patent Act*;" and Henry, J., in rendering judgment in the case, upon referring to Dr. Taché's decision in Barter *vs.* Smith, says: "Having well considered the case as presented before him, I would have come to the same conclusion as he did. I think the law as laid down and explained by him, in his exhaustive, and, I will add, able judgment, cannot properly by questioned. I fully concur in his conclusions, as I do also in his reasons." Again, by the Superior Court at Montreal, as reported in the *Mitchell* and *Hancock Inspirator Company* case, p. 2, where proceedings had been instituted for infringement of the patent in that court, and the special pleading was met by the demurrer to the effect that the nullity caused by violation of the 28th (now 37th) section of *The Patent Act*, cannot be tried by any other court than that of the Minister of Agriculture, upon which a stay of proceedings was asked for and granted, in order to obtain the decision of this tribunal. Again, in this present case, the Superior Court, at Montreal, has granted a stay of proceedings until the decision of this tribunal shall have been obtained on the question at issue.

I, therefore, hold that the Minister of Agriculture, or his deputy, has exclusive jurisdiction as to the question of the validity of the patent under the 37th section of *The Patent Act*, and cannot divest himself of it by relegating it to any other tribunal whatever.

Having thus disposed of the preliminary plea, I will now consider the case on its merits.

The first consideration which presents itself is, to ascertain the nature of the invention claimed by the patent, the claims of which are:—

First. "An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance made as described, and secured to metallic wires as set forth."

Second. "The combination of carbon filaments within a receiver made entirely of glass through which the leading wires pass, and from which receiver the air is exhausted for the purposes set forth."

Third. "A coiled carbon filament or strip arranged in such a manner that only a portion of the surface of such carbon conductor shall radiate light as set forth."

Fourth. "The method herein described of securing the platina contact wires to the carbon filament and carbonizing of the whole in a closed chamber, substantially as set forth."

It is manifestly clear that the essential feature or element of the invention, as particularly described in the first and second claims is—*a carbon filament of high resistance;* this is the novelty which the inventor has contributed to the art of incandescent lighting, and it cannot be disputed by any one having the slightest acquaintance with patent law, that the carbon filament as imported by the patentee and his representatives, the respondents, and which they still continue to import, is claimed in and covered by the patent, or that any one who should use it, without the permission or consent of the respondents, would render himself liable to them in action for infringement of the patent.

The process of further carbonizing the filament after it is introduced into the bulb, by passing an electric current through it, while a high vacuum is maintained, as described by some of the witnesses for the respondents, as well as by Mr. Edison himself, is not anywhere described or claimed in the patent, and forms no part of it; on the contrary, it is the subject of another patent, obtained subsequently, by the same inventor, Mr. Edison, on the 5th of July, 1881, under the number 13,057, the fourth and fifth claims of which are as follows:—

Fourth. "The method of treating carbon conductors for electric lamps, consisting in enclosing the conductor in a glass case or globe, exhausting the air therefrom, heating the conductor by an electric current, and then hermetically sealing the glass case or globe."

Fifth. "The method of treating carbon conductors for electric lamps, consisting in enclosing the conductor in a glass globe, exhausting the air therefrom, heating the conductor by an electric current to a higher degree than that at which it is intended to ordinarily raise the conductor in use, and then hermetically sealing the glass case or globe."

Here, then, the process is fully and explicitly described and claimed, and the use or employment of it cannot be invoked or relied on by the respondents to sustain the patent now in controversy.

The next feature of importance, after the method of securing the platina contact wires to the carbon filament, as set forth in the *fourth* claim of the patent in contestation, is the glass globe or bulb referred to in the *third* claim, and it is abundantly proved and admitted by the respondents that they have always, and still continue to import these, and have never manufactured them in Canada.

Some of the witnesses for the respondents state that the carbon filaments and the glass bulbs are exceedingly difficult to manufacture, requiring great skill and judgment, and that they cannot be made in Canada, and that there is only one factory in the United States where they can be made to the satisfaction of the respondents, but this seems irreconcilable with the statement of these same witnesses in calling these articles raw material. Mr. Edison himself, in his affidavit, referring to the glass bulbs, says: "They are strictly of the character of raw material," and in view of the fact also that the records of the Patent Office show that on November 23, 1882, Mr. Edison obtained a patent for the process of manufacturing glass bulbs for incandescent lamps from pot glass. The allegation of inability to manufacture in Canada is no plea in defense of a Canadian patent, and it would be a singular misconception of the spirit of the law if a patentee, probably holding a patent for his invention in the United States, or other foreign country, should suppose he could hold to his Canadian patent, declare his inability to manufacture it in Canada, ignore the fact he was thereby preventing any one else from engaging in the industry, and defeating the very object and intention of *The Patent Act*, enacted to encourage and protect home labor and manufacture.

The bamboo cane was, and continues to be, imported from Japan into the United States, by the respondents, in its natural state, and was there by a series of manipulations or processes, reduced to a filament of required size and proportion, and was then further subjected to the very difficult and delicate process of carbonization, and in this state was imported into Canada expressly for use in the lamps.

The platinum, another component part of the invention, was, and still is, imported into the United States from Russia, by the respondents, and was there melted and alloyed with iridium, drawn into wire, and otherwise specially prepared, and then imported into Canada for use in the lamps.

I find that every essential feature, element and component part of the invention was, and still continues to be, imported into Canada by the respondents, in a manufactured state, for the especial purpose of assembling or putting them together, so as to make them an incandescent electric lamp, such as that described and claimed in the patent held by them, and now in dispute.

The two cases of *Ayer* and *Grinnell* in the *Supreme Court*, referred to at the argument, but not yet reported, do not apply to the present case, as those two suits were brought under the *Customs Act*, in virtue of which the defendants had a perfect right to import the articles separately, and if afterwards, by compounding or combining these together, they manufactured an article or commodity, of greater commercial value, subject to a higher tariff duty, they contravened no section of the *Customs Act* giving them the exclusive right to manufacture, on condition that they should not import, such as that in *The Patent Act*, which gives the inventor the exclusive right to manufacture his invention, on condition that he shall not import it; there is, therefore, no analogy between those two cases and the one now under consideration.

I, therefore, hold that the patentee and his representatives have imported into Canada since November 17, 1880, and still continue to import, the various elements and parts comprising the invention claimed in the patent No. 10,654, in a manufactured state, and that they have not at any time since the date thereof manufactured the invention in Canada.

In view of the above, I do not consider it necessary to do more than refer to the other point raised in the case—that of

refusal to sell, and even if I had to pronounce upon this point, it is more than probable I would entertain a view adverse to that ably contended for by the respondents.

Considering that the Commissioner of Patents is presumably the parent and natural protector of patents, and should extend a liberal interpretation to matters urged in their defense, consistently with a just appreciation of public interests, and in view of the importance of this case, and the large interests involved, I have bestowed upon it all the care, study and consideration which my time and ability permitted, in the endeavor to arrive at a sound, just and equitable conclusion.

I accordingly decide that the patent granted to Thomas Alva Edison, on the 17th November, 1879, under the number 10,654, for the *Edison Electric Lamp* has become null and void, under the provisions of the 37th section of *The Patent Act*.

R. POPE,
Deputy Commissioner of Patents.

Department of Agriculture,
Patent Office,
Ottawa, 26th February, 1889.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From February 19, to March 12, 1889 (inclusive).

Alarms and Signals:—*Door Spring Connection for Electric Burglar Alarms*, J. Geary, 398,144, February 19. *Electric Burglar Alarm*, L. A. McCarthy, 398,420, February 26. *Electric Signal for Engine Shafts*. J. C. Ricketson, 399, 163, March 5. *Transmitting Instrument for Electric Signaling Apparatus*, W. J. Dudley, 399,505. *Semaphore Signal*, F. Stitzel and C. Weinedel, 399,579, March 12.

Clocks:—*Electric Alarm Clock*, S. Kahan and A. W. Craven, 398,896. *Self-Winding Electric Clock*, F. W. Brainerd, 399,128, March 5.

Conductors, Insulators, Supports and Systems:—*Insulator*, W. C. Brown, 398,025, February 19. *Telegraph-Cable*, W. R. Patterson, 398,441 and 398,442. *Insulating Support, for Electric Conductors*, S. H. Short, 398,661, February 26. *Hydraulic Press for Covering Electrical Conductors with Soft Metal*, W. Siemens, 399,291. *Underground Electric Wire Conduit*, W. L. Penney and T. Little, 399,343. *Telephone Line Cable*, G. F. Shaver, 399,635, March 12.

Distribution:—*Electric Converter*, L. Gutmann, 397,910. *Equalizer for Electric Currents*, S. Bergmann, 398,121, February 19. *Regulator for Systems of Electrical Distribution*, L. B. Stillwell, 399,218. *Method of Regulation for Systems of Electrical Distribution*, same, 399,219, March 5. *System of Electrical Distribution and Conversion*, T. H. Hicks, 399,534. *System of Electrical Distribution*, G. Westinghouse, Jr., 399,639, March 12.

Dynamos and Motors:—*Alternate-Current Electric Motor*, O. B. Shallenberger, 398,457 and 398,458. *Regulator for Dynamo-Electric Machines*, E. A. Sperry, 398,668. *System of Synchronizing Electric Motors*, F. J. Patten, 398,794, February 26. *Electric Motor*, O. Lugo, 399,059. *Dynamo-Electric Machine*, W. L. Silvey, 399,068. *Regulator for Dynamo-Electric Machines*, J. F. Kester, 399,147. *Dynamo Electric-Machine*, J. H. Robertson, 399,213, March 5. *Dynamo Machine*, G. L. DuLaney, 399,320. *Dynamo Armature*, J. A. Hayes, 399,328. *Commutator for Dynamo-Electric Machines, and Electric Motors*, B. Heywood, 399,329. *Prevention of Sparking in Dynamo-Electric Machines and Electric Motors*, G. Higham, 399,401 *Prevention of Sparking in Electric Generators and Motors*, same, 399,402. *Dynamo-Electric Machine*, same, 399,403 and 399,404. *Switch for Electric Motors*, A. H. Eddy, 399,507, March 12.

Galvanic Batteries:—*Electric Battery*, E. A. Sperry, 397,945. *Electrical Battery*, W. Burnley, 397,965. *Galvanic Battery*, E. D. Cross, 397,969 and 397,132, February 19. *Mercury Holder for Battery Zincs*, W. P. Kookogey, 398,737, February 26.

Ignition:—*Electric Gas Lighter*, E. Kronenberg, 399,416, March 12.

Lamps and Appurtenances:—*Electric Lighting System*, J. A. Galvin, 397,906. *Electric-Lamp Hanger*, M. M. Wood, 397,953, February 19. *Incandescent Electric Lamp*, T. A. Edison, 398,774, February 26. *Hanger-Board for Arc Lamps*, J. J. Wood, 396,870. *Arc Lamp*, W. L. Silvey, 398,906. *Electric Arc Lamp*, same, 398,907; G. M. Lane, 399,054. *Electric Lamp Fixture and Switch*, L. W. Dillon, 399,134, March 5. *Combined Gas and Electric Light Fixture*, J. C. Cassidy, 399,497, March 12.

Measurement:—*Electric Meter*, E. F. H. H. Lauckert, 399,836, March 12.

Medical and Surgical:—*Electric Belt*, S. DeBaun, 398,133, February 19. *Couch for Applying Electrical Treatment*, J. B. Schmalz and J. B. Faulkner, 399,064, March 5.

Metal Working:—*Method of Manufacturing Screws and Bolts by Electricity*, E. Thomson, 398,912. *Electrical Welding Machine*, same, 398,913. *Electric Metal-Working and Welding Machine*, same, 398,914. *Process of Electric Welding*, C. L. Coffin, 399,019, March 5.

Miscellaneous:—*Electric Current Indicator*, W. A. Carey, 397,966. *Apparatus for Bleaching by Electrolysis*, E. Hermite, E. J. Patterson and C. F. Cooper, 398,045. *Safety Gauge*, A. F. Nutting, 398,744. *Electric Circuit Coupler*, S. C. C. Currie, 398,769. *Gas Extinguisher*, A Steinhilber, 398,805, February 26. *Electric Current Regulator*, J. W. Balet, 398,926 and 398,927. *Interrupter for Electric Circuits*, I. E. Lecoultre, 399,057. *Electric Switch*, L. W. Dillon, 399,135. *Electrical Store Service Apparatus*, R. N. Dyer, 399,137. *Electric Cigar Lighting Device*, W. Tag and S. C. Smith, 399,168. *Electric Amalgamator*, J. H. Rae, 399,209. *Electric Regulator*, F. C. Wagner, 399,224, March 5. *Process of Duplicating Phonograms*, G. H. Herrington, 399,264 and 399,265. *Switch-Board*, J. W. Kelly, 399,269. *Electrical Measuring and Controlling Apparatus*, W. Siemens, 399,292. *Lightning Arrester*, C. H. Wilson, 399,305. *Coupling for Electric Circuits*, A. C. Griggs, 399,326. *Electrical Appliance for Stopping and Starting Elevators*, R. F. McFeely and H. V. Potter, 399,341. *Magnetic Separator*, J. A. Burden, 399,375. *Electric Circuit*, J. J. Carty, 399,377. *Electric Circuit Protector*, W. B. Harvey, 399,400. *Electric Switch*, H. T. Paiste, 399,550. *Coin-Operated Induction-Coil*, P. G. Williams and A. W. Roovers, 399,591. *Regulator for Electrical Machinery*, G. H. Condict, 399,599, March 12.

Railways and Appliances:—*Driving Mechanism for Cars*, F. J. Weis, 398,207, and 398,208 and 398,209. *Railway Car*, J. A Brill, 398,222. *Cable Railway System*, C. J. Van Depoele, 398,294, February 19. *Current-Collecting Device for Electric Railways*, R. M. Hunter, 398,402. *Support for Electric Railway Wires*, T. H. Brady, 398,489. *Conductor for Electric Railways*, O. Dahl, 398,498. *Electric Brake for Railway Trains*, A. H. Bowman and W. P. Widdifield, 398,577. *Electrical Railway Signal*, H. Hayden, Jr. and W. F. Z. Desant, 398,613. *Electric Railway*. S. H. Short, 398,662. *Switch Mechanism for Electric Railways*, same, 398,663, February 26. *Electrical Tramway*, H. T. Blake, 398,814. *Crossing-Conduit for Electric Railways*, I. W. Heysinger, 398,963. *Electric Railway*, H. W. Smith, 399,091. *Electric Car*, same, 399,092. *Electrical Railway Signaling Apparatus*, H. J. Palmer, 399,155. *Circuit-Closer for Railway Car Telegraphs*, G. I. Hopkins, 399,228, March 5. *Electric Railway*, J. B. Blair, 399,236. *Electric Railway Switch and Alarm*, W. S. Hull and J. C. Anderson, 399,331. *Electric Railway System*, C. S. Bradley, 399,372. *Conductor for Electric Railways*, R. M. Hunter, 399,409. *Railroad Signaling Device*, F. P. Benjamin, 399,474. *Electric Railway Signal*, T. A. B. Putnam, 399,556, March 12.

Storage Batteries:—*Secondary Battery*, J. T. Pedersen, 398,075; I. A. Timmis, 398,194, February 19. *Electrode for Secondary Batteries*, E. M. Lang, 398,409, February 26. *Secondary Battery*, E. R. Knowles, 399,052 March 5. *Secondary Battery Electrode*, A. V. Meserole, 399,274. *Secondary Battery*, J. L. Huber, 399,535, March 12.

Telegraphs:—*Telegraphy*, C. E. Dressler, 397,977. *Floating Telegraph Station*, U. Dieuleveult, 398,035, February 19. *Quadruplex Telegraphy*, C. L. Healy, 398,614. *Stock Indicator*, J. A. Enos, 398,713, February 26. *Printing Telegraph*, F. H. W. Higgins, 398,833. *Automatic Telegraphy*, J. O'Neil, 399,154, March 5. *Telegraph System*, W. Burnley, 399,314, March 12.

Telephones and Apparatus:—*Stretcher for Mechanical Telephone Line Wires*, A. W. Butterworth, 399,016. *Telephone Exchange*, W. B. Vansize; reissue 10,969, March 5.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in March 1889.

Reported for the ELECTRICAL ENGINEER, *by* F. B. Brock, *Patent Attorney* 639 *F street, Washington, D. C.*

Electro Magnet, I. P. Tice, 125,151, April 2, 1872. *Distributing Electricity for Gas Lighting*, S. Gardiner, Jr., 125,387, April 9, 1872. *Electro-Magnetic Engine*, W. G. Thornton, 125,504. *Electro-Magnetic Watchman's Register*, W. D. Sheppard, 125,624. *Telegraph Apparatus*, G. Little, 125,582, 125,583, 125,584, 125,585, 125,586 and 125,587, *Electrical Safe Protector*, Rowell and Duncan, 125,693, April 16, 1872. *Telegraph Sounder*, M. N. Goodyear, 125,806. *Printing Telegraph*, R. H. Gallagher, 126,048, April 23, 1872. *Insulator*, J. I. Conklin, Jr., 126,027. *Insulator Fastening*, D. Doren, 126,038. *Unison Stop for Printing Telegraph*, M. F. Wessman, 125,920. *Electrical Alarm for Bank Safes*, Butler & Parmelee, 126,263. *Electrical Lining for Safes, etc.*, N. B. Guernsey, 126,289. *Electrical Torch for Lighting Gas*, W. W. Batchelder, 126,251. *Electro-Magnetic Alarm*, N. B. Guernsey, 126,287 and 126,288. *Telegraph*, N. B. Guernsey, 126,290. *Printing Telegraph*, G. B. Scott, 126,336. *Printing Telegraph*, G. M. Phelps, 126,329. *Printing Telegraph*, H. VanHoevenbergh, 126,353. *Collecting Electricity for Telegraphing, etc.*, W. H. Ward, 126,356, April 30, 1872.

[Drawings and specifications of any patent will be furnished by Mr. Brock at cost, 15 cents each.]

THE

ELECTRICAL ENGINEER.

Conducted by F. L. POPE AND G. M. PHELPS.

PUBLISHED MONTHLY AT

11 Wall Street, New York City.

Single Copies,	.30

[*Entered as second class matter at the New York, N. Y., Post Office, April 9, 1888.*]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VIII. NEW YORK, MAY, 1889. No. 89.

A CENTENNIAL REFLECTION.

THE electrical engineer has much more than half a hundred years to wait before he can commemorate the centennial of his art. Indeed, it would be somewhat difficult to fix upon a precise period of time when the applications of electricity to the useful arts acquired a range and magnitude sufficient to justify the use of the term "engineering" to describe their practice. Telegraphy, prior to submarine work on a large scale, scarcely called for the resources of the engineer, properly so-called; ocean telegraphy for over thirty years has demanded engineering talent of a high order; but not till the advent of electric lighting, following the successful generation of electricity in large quantities by mechanical means, did the electrician have to become in a large way an engineer. Mechanical engineering now fills quite as large a place as the proper skill of the electrician in the great electrical industries of lighting and the transmission of power.

But it is not our purpose to seek a date whose hundredth anniversary our successors of the twentieth century may celebrate as the birthday of electrical engineering; but rather to direct attention to a particular reason for a hearty participation by electricians in the centennial festivities just closing.

In orations and in the daily press the transcendent merits of the Constitution, which was finally started on its course by the inauguration of Washington as president of the United States, have been generally and adequately set forth, both on this and preceding anniversaries, and it would not be fitting in a technical journal to enlarge upon the general theme. But the Constitution contains one provision to which we may well direct notice at this time, namely, the provision for a system of patents for inventions in the useful arts.

"The Congress shall have power * * * to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries."

The wisdom and justice of this clause, from the section of the Constitution prescribing the powers of Congress, as disclosed in their effect upon the industrial development of the United States, signally illustrate the far seeing prudence of the framers of our organic law. It would seem that only eyes dimmed by enviousness or stinginess can fail to see that the patent system founded upon this constitutional power has been a chief factor in the marvelous growth and diversification of our industrial arts.

We would not be counted among those who extol our material prosperity and national wealth as the chief benefits to be reaped from the wise sowing of the fathers; these things are good—they are not the best fruits; but our attention is now upon a limited part of the field, and that part has borne fruit for no class of workers in "science and useful arts" in greater abundance than for electricians. Our art, scarcely dreamed of when the Constitution was written, and still so new that many men are living who saw its beginnings, has entered field after field of usefulness, and now seems likely at no distant day to enter every workshop through its latest application—the transmission of power.

Does any electrical inventor or engineer believe that all or nearly all this could have been achieved without the protection of property in invention or discovery secured through the patent system? We think not. Let us add to our participation in the general felicitation attending the Centennial of Washington's inauguration and the establishment of the government of the United States, a special recognition of the value of that provision of the Constitution upon which was based the liberal patent system which has done so much to stimulate advancement in our own and other arts.

THE WESTON SECTIONAL ARMATURE PATENT.

IT looks as if the Westinghouse Electric Co. in acquiring control, through the United States Electric Lighting Co., of the recently issued patents of Mr. Weston for sectional armatures for dynamo-electric machines—an abstract of which we print in another column—has scored a point of some importance in the general electrical situation. The history of this patent is briefly as follows: In 1882 applications were filed in the Patent Office by Thomas A. Edison and Edward Weston, the former on August 14th and the latter on September 22d, in which both parties claimed an armature made of iron plates separated by interposed insulating material and mounted on an insulated shaft. Weston, in addition to this, also claimed broadly the armature when constructed of iron plates with interposed insulating material, without reference to the shaft or the type of armature. By some oversight Edison's patent was allowed to issue prematurely on October 10th, 1882, but an interference nevertheless proceeded and was

finally terminated in regular course by a decision awarding priority of invention to Weston. The Patent Office refused meantime to issue Weston's broad claim until the interference on the specific claim was decided, and hence it has remained pending for several years. The scope of the patent, as now issued, is apparently broad enough to cover not only dynamo and motor armatures but converters as well.

The Westinghouse company, with its characteristic energy, lost no time in commencing a suit to test the validity of the patent, selecting as a defendant the Manhattan Electric Light Co., of New York city, which operates what is known as the Fort Wayne or Slattery system. The Edison Electric Light Co., it appears, were wise enough to protect themselves in season by arranging for a license under the Weston patent, so that their manufacture and sale of apparatus containing the invention will not be interfered with. Nevertheless, there must be many thousand of dynamos and motors in the United States, in which the combination claimed forms an essential feature, and which have been put on the market by other parties. The issue of this patent, by the way, indicates pretty conclusively one of the objects which the recent arrangement between the Westinghouse and United States companies was designed to accomplish. The legal situation in the immediate future is likely to become exceedingly interesting.

"HOW IT STRIKES A CONTEMPORARY."

Journalism in America, like everything else in that go-ahead part of the globe, is much afflicted with a tendency to boastfulness. True, there is, in many cases, something to boast about, but the way in which many of our otherwise estimable contemporaries in the electrical field talk about themselves, their energy, progress, and enterprise, makes us smile, sadly smile, to see such excellent, well-conducted journals depart so far from the paths of modesty. The copies latest to hand of two well-known American electrical journals, one from New York the other from Chicago, run each other very close in a bragging competition. We rather fancy Chicago scores in this particular competition, if not in the journalistic one.—*Electrical Review*, London, March 15.

The particular horn-blowing referred to in the above paragraph was merely somewhat more vociferous than the habitual tooting of some of our esteemed brethren. Their unmelodious and discordant notes seem to vary in pitch and blatancy only with the supply of wind. The persistence of the habit on the part of some highly valued exchanges is the more surprising because its indulgence is worse than unnecessary, and must, we should imagine, be offensive to such of their readers—the majority, we are sure—as are quite capable of discovering for themselves the enterprise of the editors and publishers in producing a valuable journal, and can, by the aid of simple arithmetic, or a pair of scales, even determine how much bigger than usual a particular issue may be.

One of the very best electrical journals in the country is a notorious offender, accompanying its serial tooting by a sort of drone bass, like a bagpipe, from an automatic horn (electrotyped apparently), which never stops its strident proclamation of the antiquity of the journal and its precedence of all others in entering the electrical field. The burden of this particular toot sounds oddly in the ears of those who are familiar with the course of electrical journalism in America, and particularly to such of them as occasionally look over old files and may have come across some remarks of the present principal proprietor, and recent editor-in-chief, of the journal we have in mind—who once conducted a paper of a different class—in disparagement of electrical journalism and of the prospects of two periodicals which had already entered that field ahead of his present publication. We congratulate him upon the promptness with which he discovered his mistake, and no less upon the excellence of the electrical journal which he soon afterwards began to publish and still maintains.

The timely comment of our valued London contemporary has suggested these remarks; which we make in more sorrow than anger, and solely in the interest of a more dignified tone in the electrical press. Why not try the experiment of hanging up the fish-horns for a while, brothers, and of trusting to the acumen and good sense of readers to discover your enterprise and your excellence?

AS TO THE BATE CASE.

A valued correspondent, whose letter we printed in the April number of the Electrical Engineer, criticizes the opinion editorially expressed in our issue of the preceding month, to the effect that under the doctrine announced in the Bate decision the premature termination of foreign patents through failure of the patentee to pay taxes will hereafter be likely to affect adversely a previously issued United States patent for the same invention.

Of course, our opinion must be taken for what it is worth; but to prevent misapprehension, we take occasion to state most emphatically that we regard the enactment by which the duration of a prior foreign patent is permitted to affect in any way the value or duration of the domestic patent as a relic of mediæval barbarism and a disgrace to our statute book, which ought to be summarily swept away. The Canadian statute which declares a patent void by reason of importation or non-manufacture is not a whit better; they are both of them the outcome of the absurd notion, which has survived from the dark ages, of trying to "protect" industry by interfering with it in every possible way. It is not our province as journalists to defend the statutes or the decisions, but to say what we think their effect will be likely to be under certain contingencies. It is quite true, as our correspondent contends, that the point referred to was not actually decided in the Bate case, and we are forced to admit that it would not be an unprecedented circumstance if the next time the question comes up the Supreme Court should decide it exactly contrary to the logical deduction which necessarily follows from the text of its opinion in the Bate case. The assumption of our correspondent that the action of the Supreme Court would be in the line of aiding the patentee seems to us, however, to be quite destitute of adequate foundation. A collation of the opinions rendered by it since the celebrated case of the Bridgeport Brass Co. would, on the contrary, indicate that the settled policy of the court has apparently been to decide every case adversely to the patentee, if at all possible to do so, either by declaring the patent void, or else by holding that the defendant had not infringed. We do not know that the point in question is likely to come before the Supreme

Court in the near future, and we are well aware that the situation may undergo much change before it does, but in the meantime we must say that we do not see reason for revising our original opinion.

The American Institute of Electrical Engineers will hold its annual meeting May 21st and 22d. The business meeting, for the election of officers, reception of reports and consideration of the affairs of the Institute, will be held at the house of the Society of Civil Engineers Tuesday evening, 21st. The general meeting for the hearing and discussion of professional papers will take place on Wednesday, 22d; the morning session at the house of the Society of Civil Engineers, and the afternoon session at the College of the City of New York, where electrical apparatus will be provided for experiments required in illustration of some of the papers. Before leaving the house of the Civil Engineers to attend the afternoon session the members of the Institute and their guests will partake of luncheon and enjoy an hour of social pleasure.

The papers announced for the general meeting are the following:—

"Modern Views as to the Nature of the Electric Current," with experiments, by Professor H. A. Rowland; "The Inherent Defects of Lead Storage Batteries," by Dr. Louis Duncan; "Magnetism and its Relation to Induced Electromotive Force and Current," by Professor Elihu Thomson; "The Regulation of Dynamos and Motors," by Dr. Schuyler S. Wheeler; "The Measurement of Telephonic Currents," by Professor Chas. R. Cross; "A Series of Tests on the Life and Efficiency of Incandescent Lamps," by W. H. Peirce, of the Chicago Burlington & Quincy R. R.; "Some Results with Storage Batteries in Train Lighting," by Alexander S. Brown, of the Pennsylvania R. R. These titles constitute a judicious combination of theoretical and practical topics, all closely related to contemporaneous investigation and practice. A more timely and admirable programme could not be desired.

It is hardly necessary to remind our readers that the Institute of Electrical Engineers invites and desires the presence at its meetings of all persons interested in electrical progress.

Judge Wallace's decision against the Western Union Telegraph Co. (of which we print the essential parts in other columns) seems to have had the effect of breaking the deadlock between the Board of Electrical Control and the electric companies generally. A vigorous campaign of pole chopping was immediately afterwards begun under orders of the Mayor, and it still goes on. Commissioner Gibbens appropriately headed the first attacking party, directing the movements of the axemen from the top of a lumber pile in Union square. Poles have fallen thick and fast for some weeks, and a large stock of second-hand wire and line material has fallen into the hands of the Department of Public Works. The wires removed cover a variety of electric service, but were mainly the property of the telegraph and electric lighting companies. Both these services suffered interruption or suspension. This was less serious for the telegraph company than for the electric light companies. The considerable number of people who have lost their electric light service, and the wayfarers through darkened streets, will be consoled by the reflection that they are martyrs in a great cause. No doubt the telegraph and electric lighting companies will find their inconvenience and losses alleviated by a similar reflection.

OBSERVATIONS.

Not many days ago, there was a committee hearing in the Canadian House of Commons, at Ottawa, at which one of the Honorable Members who advocated compulsory underground wire legislation turned out the following piece of logic:—"I am informed that some years since, the English courts declared that in the eye of the law, the telephone is a telegraph; therefore it is plain that the electric light also is a telegraph; and it follows, Mr. Chairman, that all electric wires are telegraph wires."

There would, however, seem to be something of a hiatus between the law and the logic of the above proposition.

. . .

Time was, when newspaper science, especially electrical science, was a thing to be scoffed at, by the initiated. But the newspaper is the mirror of the world, and electricity being now a popular fad is now constantly reflected in the said mirror. True it is, that the reflection is sometimes distorted, but that counts for nothing with the people; and it is very bad form to disagree with or to know more about one's own vocation than do the daily newspapers.

Since this is so, what happiness to realize that the electrical utterances of the daily press can now be relied upon as furnishing the latest and newest information! It is quite certain that many electricians will be both pleased and profited by ascertaining from the columns of the Boston *Globe*, that:—"The power of resistance or the unit of an ohm is equivalent to one ohm passed through one yard of mercury." It is gratifying to find that the true value of the ohm is finally determined.

The Boston *Advertiser*, not to be outdone as a science expounder then tackles the art of electrical welding, and after giving a really creditable account of the way the thing is done, says:— "The principle of this process is so simple and so direct that the wonder is nobody thought of it before. It is based on the incandescence of the carbons in the arc light."

. . .

In recent legislative hearings the allegation was made that the Western Union Telegraph Co. has for years used a potential difference of 400 volts on its lines without hurting or inconveniencing anybody; and the inference drawn or intended, was, that, therefore, an E. M. F. of 400 volts was under all circumstances innocuous when employed on electric railways and elsewhere.

Whether or no the electric railways always restrict themselves to a voltage of 400, it seems scarcely logical to arrive at a conclusion based upon incomplete premises.

From such reports as are available in this case, nothing was said of the resistance of the circuits upon which the Western Union uses such an E. M. F. and it is evident that there may be such a resistance as will reduce the current to a very low point indeed. The experience of most of us leads to the opinion, that even comparatively low electromotive forces *may* under certain conditions, and where the currents are of great volume, be dangerous; equally with currents of less volume and higher E. M. F. That is, both E. M. F. and C. must be of considerable strength before the danger element appears.

Who ever heard of the current developed in a speaking telephone hurting anybody? Yet it is incontestable that the currents generated in a telephone circuit are developed under an enormous E. M. F., because they can manifest themselves, and perform their legitimate work, in circuits in which a dozen persons taking hold of hands are included, or otherwise including great resistances.

It may be feared that the 400 volt statement, while well adapted to work upon the non-electric mind of the legislative committee-man, was a trifle dis-ingenuous.

ARTICLES.

THE THOMSON-HOUSTON ELECTRIC RAILWAY SYSTEM.

When the Thomson-Houston Electric Co. entered the field of electric railways one of their first steps was to purchase the patents owned by the Van Depoele Electric Manufacturing Co., and to secure the services of Mr. Van Depoele, the inventor of the system which bears his name, whose valuable services are still retained by them. At that time the Van Depoele company had equipped 12 railways with its system, and had taken a leading part in demonstrating the practicability and commercial success of electric traction. Mr. Van Depoele was one of the earliest workers in the application of electricity to car traction in this country; and it is not too much to say that the rapid development of electric street car service has been very largely along the lines pursued in his work. This is particularly true in respect to systems of conductors, Mr. Van Depoele having persistently adhered to the use of overhead wires, a method now employed on nearly all the roads that are in successful operation. The Thomson-Houston company did not adopt the Van Depoele system entire, but after careful study selected the best features, which, supplemented by the work of the electricians and engineers of the company, resulted in the making of a number of changes conducive to the general perfection of its railway apparatus and appliances. It was therefore determined :—

(1) To place the motors underneath the car bodies, instead of on the front platform, and to arrange them so that they would not project above the car floor, or necessitate the changing of the car body in any way.

(2) That direct gearing be used.

(3) That ordinarily each car be equipped with two motors driving the axles independently of each other, except in cases where the grades are very slight indeed, when one motor may be used.

(4) That it is not expedient to apply the motors to ordinary running gear, but that specially designed trucks should be used.

(5) That the motors be mounted on the trucks so as to be entirely independent of the car body.

Many new and valuable features of importance were added to the apparatus from time to time, resulting in continuous improvement of the system through combining the experience of the electricians of the Thomson-Houston company with that of Mr. Van Depoele. Some of these additional features will be mentioned in the description which follows. They include, in addition to the specially constructed motors, special switches for car work, fuses, lightning arresters and controlling devices.

The Thomson-Houston company has confined itself to the overhead system of conductors in its railway construction, being convinced from the results of experiment and practical experience that this was the most desirable and economical method that could be employed in present practice.

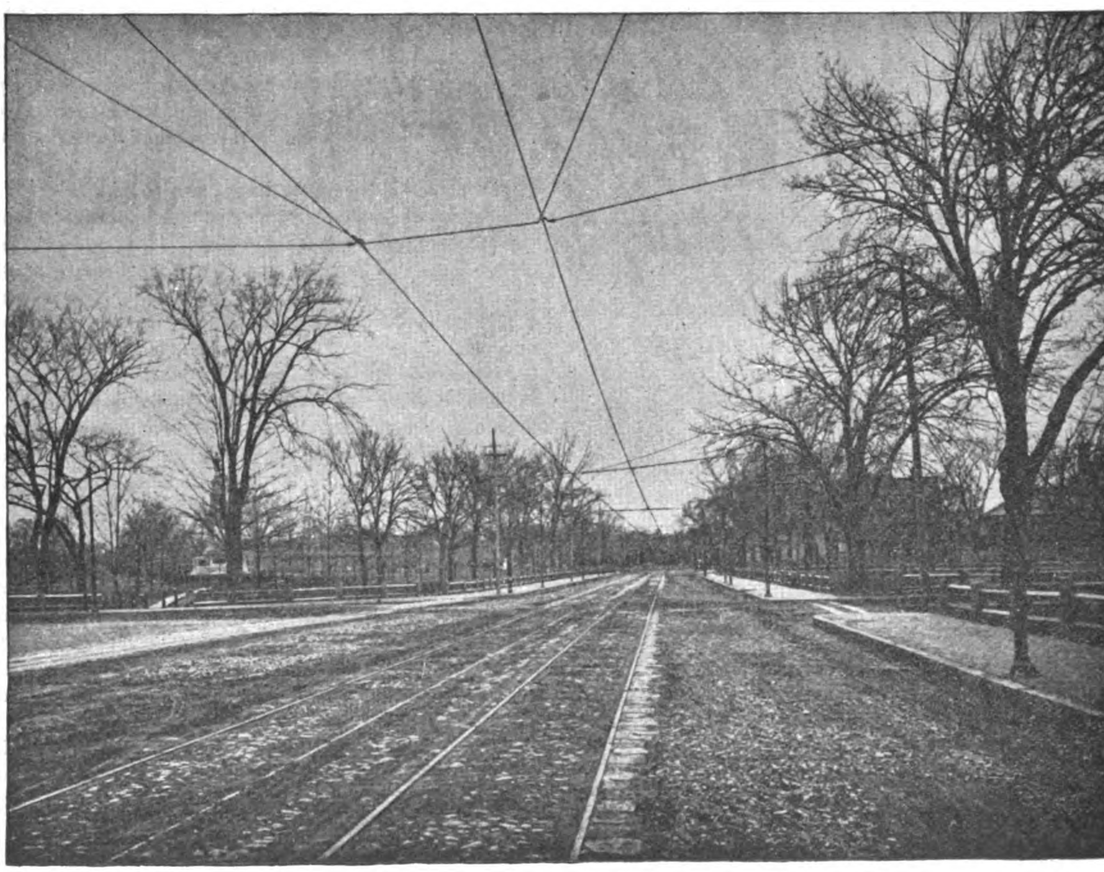

Fig. 1.—West End Street Railway, Boston, Cambridge Division.

The main conductor in most cases, therefore, consists of a stout, bare copper wire, fed with the current at any convenient point or points, and is stretched above the roadway on suitable supports, the contact to such line being made with a trolley underrunning the line.

The line construction has been of three kinds, termed cross suspension, single bracket suspension, and double bracket suspension.

In the cross suspension the main conductor is upheld by transverse cross wires, which are supported at intervals on poles on the two sides of the street. The poles are placed in pairs oppositely, and are joined by a light supporting

wire upon which the main conductor is carried through the medium of suitable suspending insulators. This construction is well illustrated by the Cambridge division of the West End Street Railway, Boston, Mass. (figure 1).

The second method, or single bracket suspension, is employed where the track is laid at the side of the street. In this case single brackets, attached at right angles to the poles and over the street, support the conductor. The line of the Omaha and Council Bluffs Railway and Bridge Company, Omaha, Neb., is a good example of this form of construction (figure 2).

The third mode of construction is used where there are double tracks near the middle of the street, and is particularly adapted to the case of a wide street. The two conductors are then suspended from double brackets placed at right angles to the tracks, projecting from poles set between them. One mile of the Eckington and Soldiers' Home Railway, Washington, D. C., is equipped in this way (figure 3).

When the line is long and the traffic very heavy, feeder wires are run out from the central station and connected to the circuits at the proper points. In all its work, especially on curves, the Thomson-Houston company has evidently planned to use as few auxiliary wires as possible. As can be seen from the roads already equipped, the overhead line is neat and unobtrusive, and much less unsightly or noticeable than such work is generally supposed to be by those who have not made an examination of the best constructed electric railways in the country.

THE TRUCK AND MOTOR FRAME.

The general plan of the Thomson-Houston company's motor truck will be readily understood by reference to the accompanying illustrations, figures 4 and 5. The motors are flexibly supported on the truck, are entirely independent of the car body, and, therefore, permit the ordinary car body, either of the open car type or the closed type, such as is used in winter, to be applied to the motor truck without the slightest alteration. The trucks themselves, therefore, as well as the different parts of the machinery are relatively interchangeable, the design being, as far as possible, to make all parts according to standard, whereby, they may be assembled without fitting. The gearing is planned for the simplest possible construction. It will readily be understood that the serviceability of motors under the harsh conditions of use in car service, running as they do at all speeds, and at all loads, will depend in a large measure upon the freedom from wear of the essential parts. The bearings, therefore, as well as the gearing require to be specially constructed to meet the extraordinarily severe conditions, and this remark applies particularly to the electrical details of the motors, such as the commutator and brushes and the field and armature winding. There is no question that in railway work the ability of the electrical engineer to overcome extraordinary difficulties has been severely taxed; but it is a characteristic of our time that the most difficult problems are quickly solved, and the electric motor as applied to traction is a case in point. When we realize the conditions under which this class of machinery must work in order to succeed, the results thus far obtained are truly surprising. There are the slush and mud of the street, the dry sand and grit blown about, the moisture of damp and rainy seasons and the splashing of water to attack the motor, in addition to the strains of starting and stopping, the running at varying speeds under the extreme variations of load, all of which necessarily combine to break down or deteriorate the apparatus, so that it may truly be said that the difficulties presented as compared with those in electric lighting or stationary motor transmission are very much greater. The electric motor itself, is of course, the vital element of the whole structure, and what would naturally be regarded as its weakest point would be its armature with its commutator and brushes. Each motor in the Thomson-Houston system

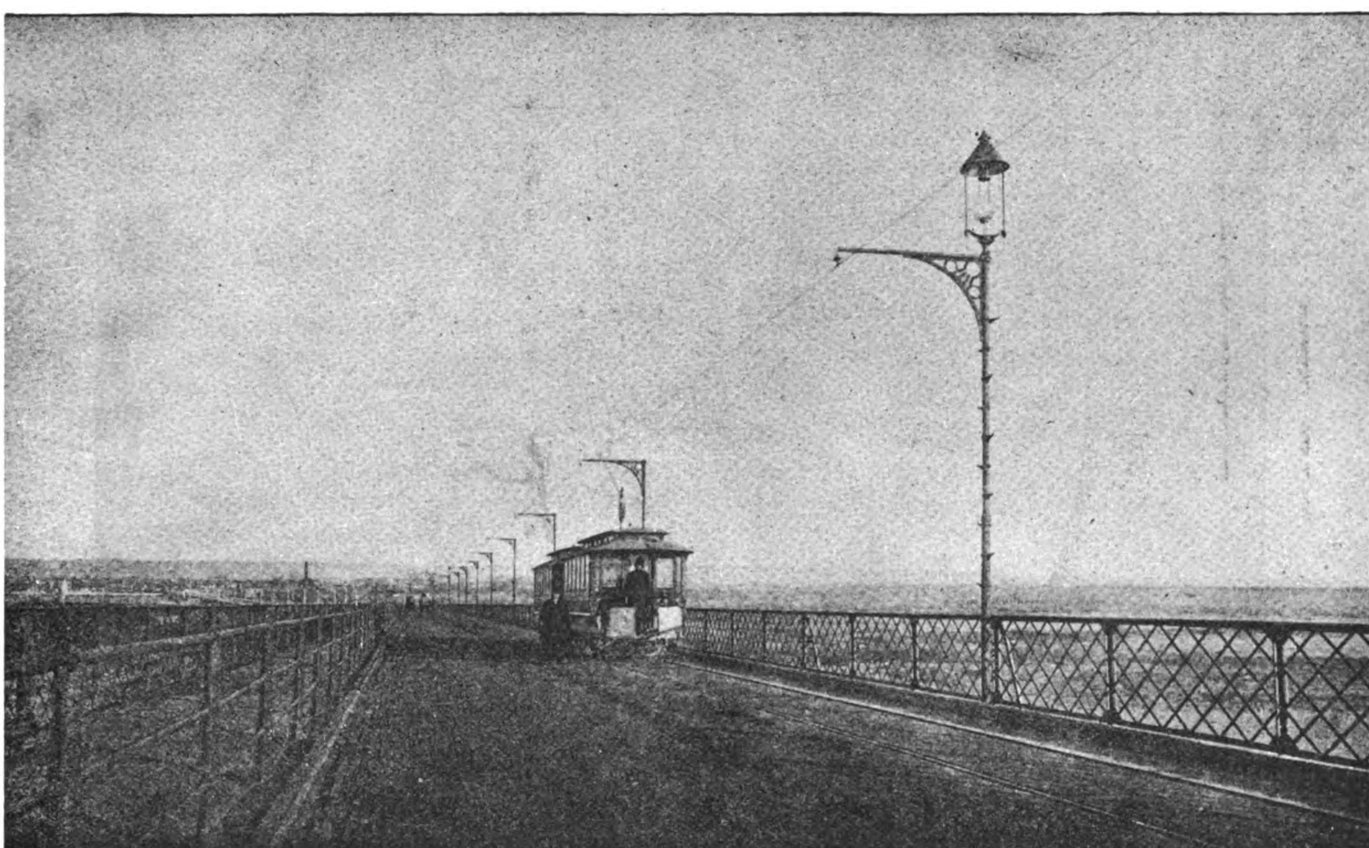

FIG. 2.—Omaha and Council Bluffs Railway and Bridge Co., Omaha, Neb.

has a single good-sized commutator with but one pair of brushes.

The brushes of the motor (see figure 8) should be specially mentioned here. The copper brush used by the Thomson-Houston company is essentially different in form and mode of application from any other. It is made of strips of copper, bound together, set at an angle to the armature shaft. It is held in place by tension springs and is always maintained at an even pressure, thus insuring evenness of wear of both brush and commutator. Its form is such that the direction of rotation of the armature can be reversed without damage or necessity for manipulation. A pair of these brushes has been in use 65 days, during which time the car covered a distance of more than 4,000 miles. Notwithstanding the excellent service of the copper brush it has been superseded by carbon, mounted in a special manner so as to secure the greatest conductivity and the several advantages which it has shown itself to possess. This improvement is due to Mr. Van Depoele who has patented it, and great credit must be given to him for his persistence in finding the conditions and construction for its best use and in overcoming the disadvantages attending the use of carbon contacts. Practice with it for a considerable time has shown it to have considerable superiority for railway work when constructed and used in accordance with Mr. Van Depoele's invention. By its use the troubles of sparking and the scoring and wear of the commutator have been greatly reduced. Favorable reports of the operation of this form of brush have been made wherever it has been tried. A pair used on the Eckington and Soldiers' Home Railway, Washington, D. C., gave a record of 41 days, during which time the car traveled 2,965 miles.

One end of the motor is hung upon the axle of the car by two large bearings, and the other end is supported by a knee fastened to the field magnet and bearing on a channel iron beam fastened at its ends to the side irons connecting the pedestals or boxes. The arrangement of the supports is such that the motor is comparatively free to swing into different positions with respect to the framing of the truck, and this enables the starting of the car, increasing the speed, or the reversal of the motor, to be made without causing undue strains on the truck frame, or the motor supports, and is particularly useful in the movement of the motor truck around curves. The bearings of the motor shaft and of the gears are all self-oiling, and are capped to protect them from the entrance of grit and dirt. The armature shaft, for example, is constructed so as to rotate while immersed in oil, so that the shaft lubricates itself continually, and by this arrangement the attention required to oil the bearings and heating of the bearings are avoided. The devices for this purpose have been found by continued use to be thoroughly well suited to the purpose for which they were designed.

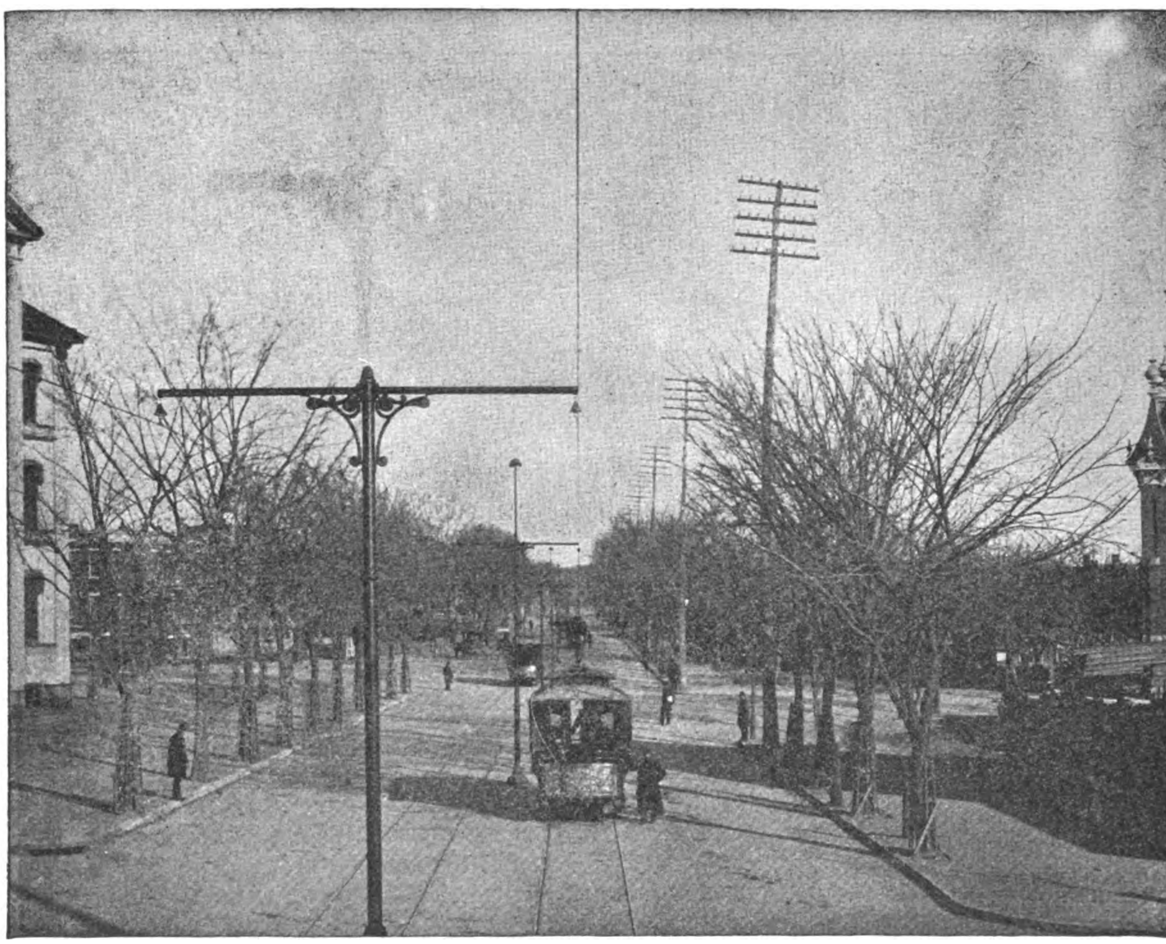

FIG. 3.—Eckington and Soldiers' Home Railway, Washington, D. C.

THE GEARS.

Only cut gears are used. The armature shaft pinion is built up of alternate discs of metal and fibrous material firmly fastened together. The intermediate gear is made of cast-iron, and is secured to a shaft having a bearing on each side of the motor frame. This preserves the parallelism of all the running shafts and prevents the possibility of the gear wearing out of line. The second pinion engages with a split gear fastened to the car axle. By this arrangement and construction of gearing much of the noise of running has been overcome, while solidity and strength are retained.

OVERHEAD CONSTRUCTION.

A single overhead conductor is the standard system, the rails being used for the return current. The structure is light and unobtrusive, and, particularly when iron poles are employed, can hardly be regarded as an obstruction or disfigurement of a city street. It is the telegraph and telephone companies with their enormous poles heavily laden with a multiplicity of wires that have evoked what public sentiment exists against overhead electric wires in general.

easy adjustment to bring the conductor directly over the track. These supports are of such shape as to hold the conductor in the plane of the cross wires, so that the transverse strain of the latter has no tendency to tip the conductor supports out of horizontal. (See detail below.) The whole arrangement at curves is light and simple, requiring but few extra cross wires, and as seen on recently constructed roads of the Thomson-Houston company, well illustrates the progress made in reliability of action as well as in simplicity and lightness.

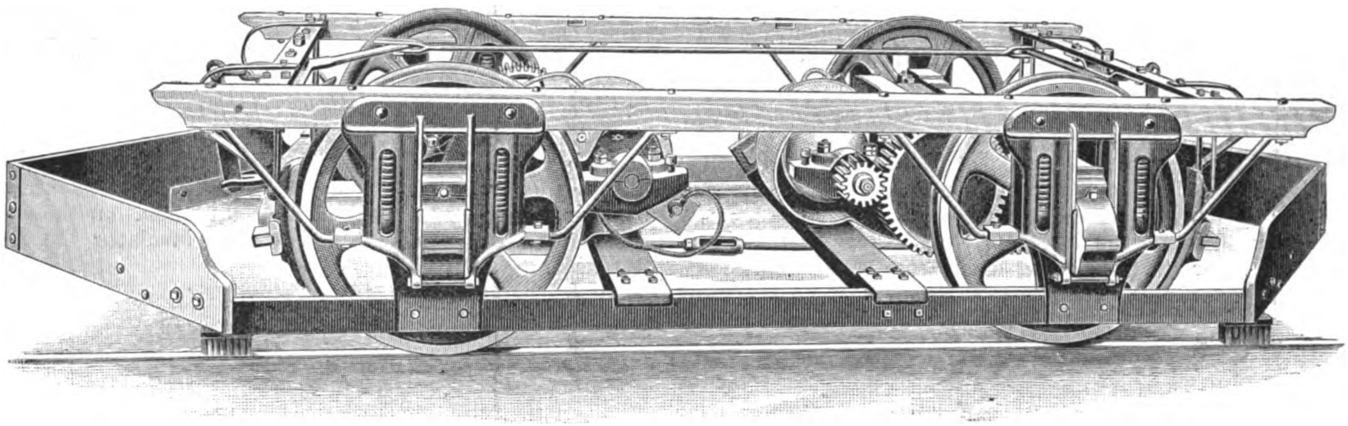

FIG. 4.—Thomson-Houston Motor Truck.

The Thomson-Houston company has done nearly all of its work with a single overhead conductor, using the rails for a return circuit, but in some cases a two-conductor system may be used.

The main conductor is supported from bracket poles on narrow streets, where the tracks are near the side of the street; or on wide avenues where poles can be placed between the tracks. In other cases the conductor is supported by cross wires reaching from pole to pole on opposite sides of the street, or from building to building where the sidewalks are narrow and permission can be obtained from the property owners to place neat and strong fastenings on the face of the buildings. Any style of pole can be used, from that ordinarily employed in telephone construction to the most ornamental form of iron pole. Poles are placed at intervals of 100 to 125 feet.

The arrangement of the overhead line at curves and turn-outs is one of the best features of this system. Light but strong metal supports are provided for the conductor, insulated from the poles, and so arranged as to permit of

On long lines the trolley wire or main conductor is reinforced by feeder wires at proper places along the line, as stated above. The feeder wires, which are run out from the power station and attached to the main conductor at suitable intervals not only serve to maintain a constant potential at all points of the line, but also to prevent a break at one point interfering with the operation of cars on other portions of the road.

Details of overhead construction are shown in the accompanying plate, figure 8. Numbers 1, 2, 3, 4 and 5 are frogs or switching boxes, used on branches, turn-outs and crossings. They are clamped fast to the underside of the wire, so that the trolley on leaving the wire enters the box on one side to come out the other, following the direction of the tracks below. At the extremity of each arm of the frog is a metal plate or tongue (see 35) soldered to the wire above and extending into the box or frog. The object of this tongue is to bring the contact wheel down below the wire sufficiently to prevent it from striking the edge of the frog as it enters the box. At the edge

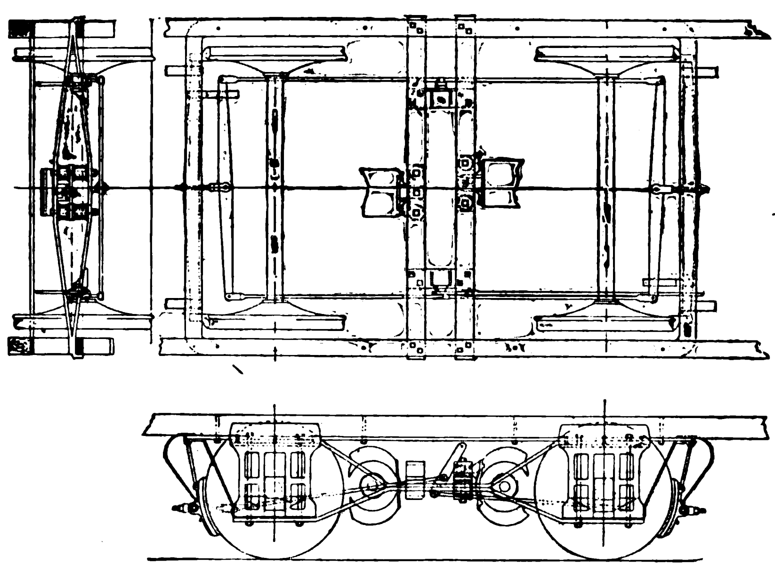

FIG. 5.—Thomson-Houston Motor Truck.

of the box the tongue is equal in depth to the depth of the groove in the contact wheel.

Number 6, is an underrunning ear, made of brass, grooved to fit the overhead conductor. The groove is turned to facilitate soldering to conductor; the upper part of the ear is provided with a projection, drilled so as to admit of suspending the ear from the insulator or bolting it to a bracket in case of a deflection in the line overhead following the track below.

Number 7, is a suspension insulator.

Number 8, is a porcelain insulator, used to improve insulation between the main conductor and the cross wire, and also to offer a large bearing surface where suspended from the cross wire. In practice, an iron wire ring of, say, number 6 galvanized iron wire is made, placed in the grooves of the insulator and closed upon it, leaving a loop at bottom to hook the suspension insulator in. This, in combination with the cone insulator (number 9), makes a very perfect insulation. The porcelain insulators are slipped on the cross wire before the latter is fastened to the poles.

Number 9, is a cone insulator, used for suspending main conductor and insulating same from cross wire. As

Number 12, insulator rod, is made of hickory turned and provided with enlarged ends bound in by a brass ferrule. Holes are drilled through this ferrule and the wood on each end; the cross wire is fastened through these holes. The insulator rod is fastened each side of the curve ear either close to the ear or close to the pole, as preferred. This insulates the main conductor from the cross wire and the poles.

Number 14, strain insulator, is made of two steel sides and two porcelain insulators two inches in diameter, $\frac{3}{8}$ steel pins holding the sides together. It is used at the terminals of lines to insulate the main conductor from poles, and is strong enough to stand the strain of the main conductor. This insulator and a large turn-buckle (19) are generally placed close together at the anchorage. It is also used whenever a strain on the line is taken up before reaching curves.

Number 15 is an insulator sometimes used in connection with the pole bracket and arm (see 26 and 27) for deflections in the line. It can be used on straight track, but the suspension ring for arm (21) and a cone insulator (9) are preferable.

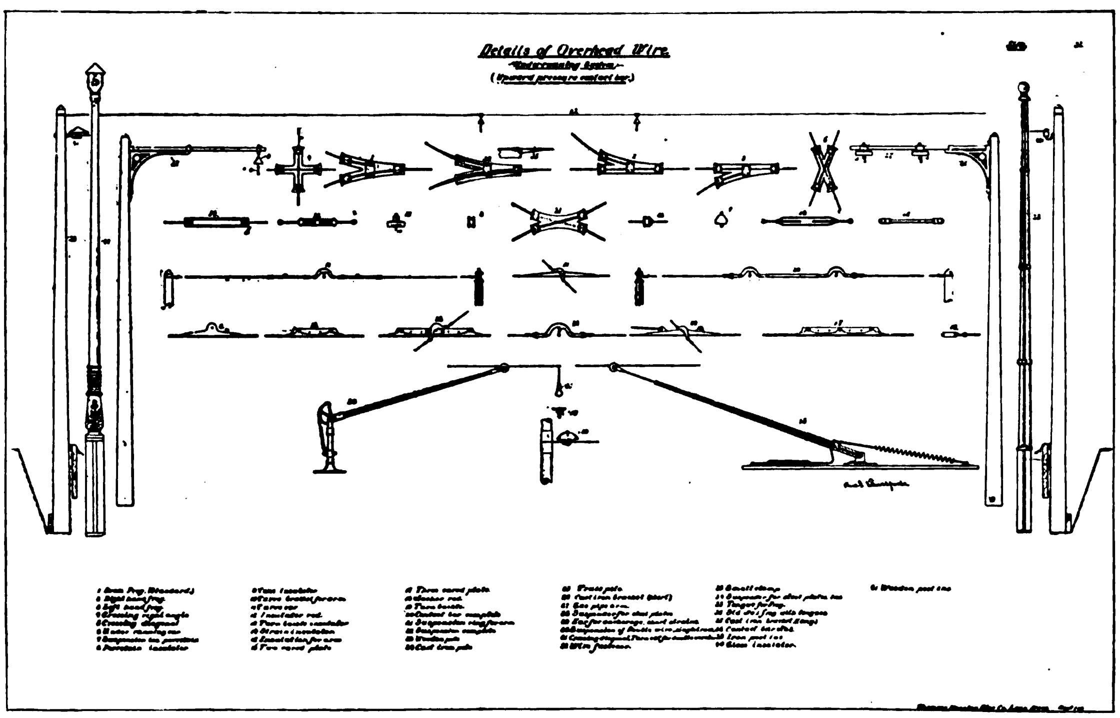

FIG. 6.—Details of Thomson-Houston Overhead Construction.

at present made, it is constructed of paper and wood, is substantial and not easily broken in transportation. This insulator can only be used on straight lines, where the wire has no tendency to pull sideways.

Number 10 is a curve bracket; this bracket is made of cast iron or brass, fastened to the insulator, and is used with the cast-iron bracket and arm (numbers 26 and 27). This method of fastening and insulating overhead conductors can be used on either straight lines or curves and deflections, although on straight lines the common cone insulator is generally used, suspended from an insulated ring, as shown in number 21.

Number 11, curve ear, mentioned above, is made of brass (gun metal). It is given a curved shape—bending above the line—in order to bring the strain of the conductor and the strain of the cross wire in the same plane, so that the curve ear will not be acted upon by a couple tending to deflect it from its proper position. The main conductor is thus held by the curve ear in line with the pull of cross wire, so that there is no tipping over caused by side strain. In order to insulate the curve ear from cross wire and poles, insulator number 12 can be used.

Number 16, two-eared plate, consists of a steel plate about two inches wide provided with two brass ears; the steel plate has drilled holes for suspension from a cone insulator, or it can be bolted to an arm or insulator (15). It is intended for fastening a conductor to an anchorage. In this case the anchor rod (18) is bolted to the steel plate and fastened by means of a wire cable to an anchor pole or other object, capable of standing the strain of the line.

Number 17, three-eared plate, is similar to the two-eared plate, but has three brass ears, and is used for taking up heavy strains and also for joining two conductors end to end.

Number 18 is the anchor rod referred to above, and number 19 is a turn-buckle.

Number 20, contact bar complete, consists of an upright shaft, carried in a cast-iron bottom plate; upon the shaft is slipped a tube to which is jointed, at its upper end, a cam; a stout spiral spring attached to the edge of the cam is secured to the collar near its junction with the bottom plate; to the cam is permanently fastened an arm carrying at its extreme end a contact wheel or trolley, grooved to run on the under side of the suspended main

conductor. The action of the cam will be well understood by reference to the figure; as the arm is depressed when the conductor is low the tension of the spring will be increased but the cam will reduces the leverage at the same time; while on the raising of the arm where the conductor is suspended higher the spring will get weaker when the cam increases the leverage; so that practically an equal pressure is exerted by the contact wheel against the conductor for all heights. The springs on the cam are adjustable. There are several other devices of somewhat different construction for making contact of uniform pressure with the conductors.

Number 21, suspension ring for arm, is a cast iron ring provided with a set screw on its upper part and an eye on its lower part. The lower eye receives the cone insulator.

Number 22 shows a suspension complete, with poles and their breast and heel plates, the cross wire, the porcelain insulator (8), the cone insulator (9), the under-running ear and conductor seen endwise.

Number 23 is a wooden pole. When wooden poles are used they are required to be at least six inches in diameter at top, twenty-one feet out of ground and six feet in the ground for ordinary work.

Number 24 is an ornamental cast iron pole, surmounted by an electric light fixture, so that at night the road can be lighted up either by the main current or by a special circuit as desired. The objection that people have to the placing of poles in front of or near their property is perfectly justifiable, in view of the kind of poles usually selected for telegraph or electric lighting purposes. In an iron pole, however, architectural taste can be displayed; and the poles instead of being an eyesore, become ornamental and in keeping with surroundings. No one objects to an ornamental or even plain gas lamp post, when properly put up; and if electric railways can be run successfully by means of an overhead wire, there can be no reasonable objection to a properly designed structure on the score of appearance.

Number 25, is a truss pole of wrought iron; seldom used. There are many varieties of iron poles. The purpose and cost usually govern their selection.

Number 26, cast iron bracket, is used with a gas pipe arm, number 27, projecting horizontally for the suspension of the overhead conductor.

Number 28 is a suspender for two or three eared plates (numbers 16 and 17).

Number 29, ear for anchorage (short strains), is used where the line has a deflection and anchorage is necessary to take the strain off the conductor.

Number 30 shows the fibre insulation between two conductors when used over a single track.

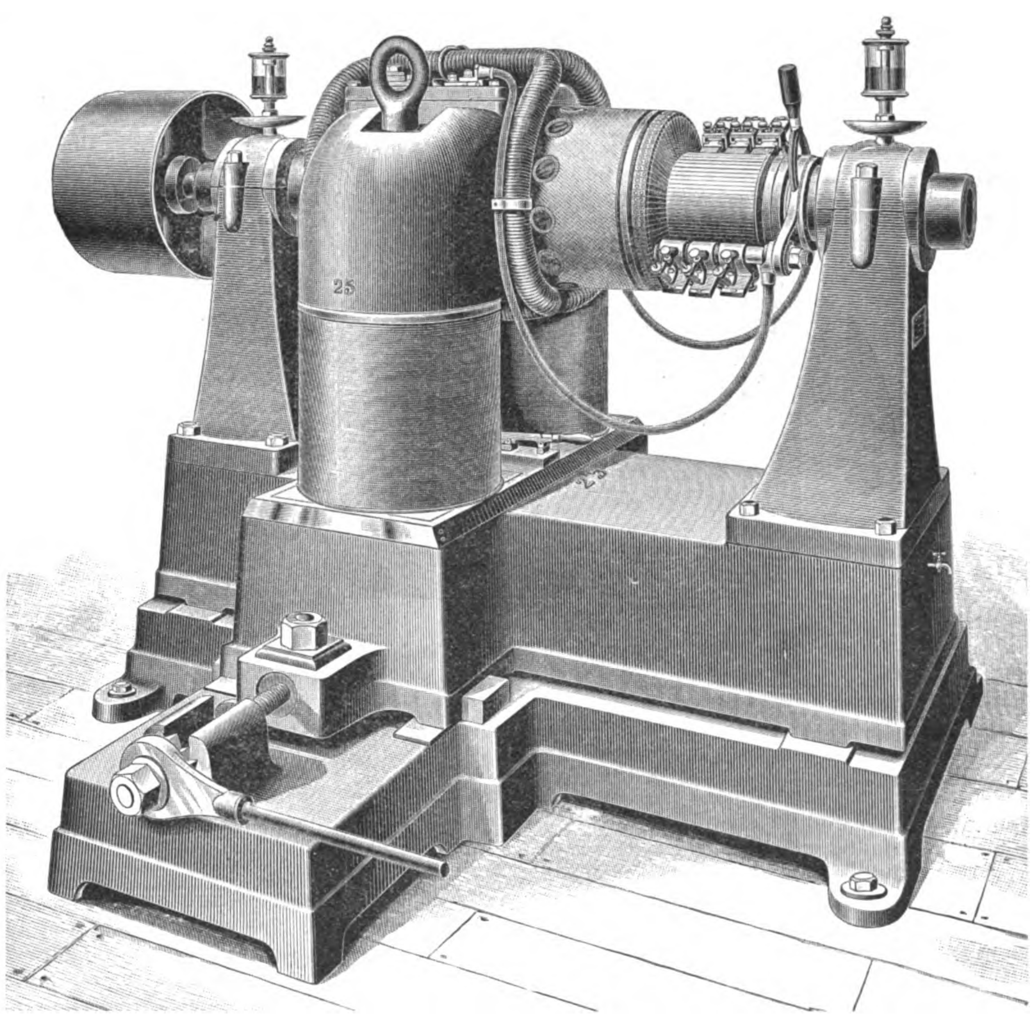

FIG. 7.—Thomson-Houston Dynamo for Railway Service.

Number 31, crossing for two wires, insulating one from the other, is used wherever it is necessary for one wire to cross another, and at the same time be insulated from it.

Number 32, wire fastener. This is used to secure a wire in a neater manner than the ordinary method of twisting it upon itself.

Number 33, small clamp to prevent the slipping of the porcelain insulator along the cross wire on deflections in the line.

Number 34 insulates, by means of a porcelain insulator and two steel straps at each end of number 28, the conductor from the cross wire. This can be used in place of number 12.

Number 35, tongue for frog, prevents the contact wheel from striking the frog box.

Number 36 represents the standard frog complete.

Number 37 represents a cast iron *tong* bracket. Number 38, contact bar number 2, is used where the track passes under a low bridge, the wire being very near the top of the car. This form of contact arm lies nearly flat upon the car when passing under a low portion of the line. Number 39, iron post insulator; number 40, glass insulator, and number 41, wooden pole insulator, are new forms not yet in use.

THE GENERATOR.

The dynamo of the Thomson-Houston railway system is shunt-series wound to give a constant potential. The shunt winding covers the cores of the field magnets in the usual manner. The series winding is peculiar, consisting of separate coils embracing the ends of the pole-pieces and encircling the armature. The circuit connections are on a switch-board, which is bolted fast to the pole-pieces at the top of the machine. (See figure 7.)

This dynamo is of the Thomson-Houston motor type, now familiar to electricians and the public. Its design and construction render all parts easily accessible. The armature bearings are supported in ball boxes, by means of which they automatically allign themselves. The machine most frequently used for railway work is of a potential of 500 volts and is capable of giving 62,500 watts output at a speed of 900 revolutions per minute. The machine is built very substantially. Its weight is 10,000 pounds.

The safety appliances provided with the machine, which are in the nature of automatic cut-offs, are generally arranged to limit the current to about 140 amperes, which is the full load; though oftentimes in railway work, the limit is set a little higher than this because sometimes it is not desirable to have the cut-off operate until a load has been thrown on and maintained which is considerably beyond the ordinary capacity of the machine.

The station equipment, which generally accompanies one or more of these generators, consists of a voltmeter, one or more current indicators, rheostats and lightning arresters for each machine, an equalizing bar to connect the series coils of the machines, and three-point station switches for cutting the current from the line. These are all mounted on a neat board and are generally placed in the dynamo room at a distance of one or two feet from the wall, so that all the connections on the back of the board may be conveniently examined at any time.

MOTORS AND CAR APPARATUS.

In most cases two motors are employed on each car, although for certain conditions one motor is quite sufficient. The motors are generally series wound, and are run in multiple when high speeds are to be obtained. The independence of the driving action of the two motors, when two are used, is obtained by gearing each one to a separate axle. The switches for throwing on and off the current and for suddenly opening the circuit, are special to the Thomson-Houston system, as are also the lightning arresters and fusible plugs. The lightning arresters protect the motors from induced discharges brought about by lightning flashes, or from direct discharges to the main line from the clouds. The fuse wires, of course, have the ordinary function of cutting off the current when it is excessive. They are made to open the circuit at about 50 amperes in ordinary cases. All of these protective devices are provided with means for rupturing any arc which may form between the terminals, either of the switches, lightning arresters or fuse connections. This is rendered desirable, if not necessary, when working with potentials so high as 500 volts, a pressure which is capable of maintaining an arc across a space of considerable length. Thus in opening a switch an arc may still play after the switch has been opened and would damage the switch and its supports. While a number of arc-rupturing devices have been applied to these switches, lightning arresters and fuses, by the Thomson-Houston company, the one which has been adopted as the standard is the magnetic field produced by a current passed through the coils of a powerful electro-magnet, in which field the switch contacts, lightning arrester plates and the fuse connections are mounted. It is understood that the Thomson-Houston company has broad patents on arc-rupturing devices applied in this manner, and which are found so useful in connection with railway work. Great care and attention has evidently been given to the construction of these accessory devices in order to have them of an efficient, practical nature. In addition each car is equipped with a reversing switch and starting rheostat. The rheostat is of special form, put in series with the motors, and enables the starting and stopping of the car to be accomplished without any jerk or sudden strains. The manipulation of the rheostat and reversing switch is accomplished from either end of the car, by what is known as the controlling stand. The field magnets are also operated upon by the controlling stand, so as to change the ampere-turns around the field magnets; and this, together with the rheostat, gives an efficient and thoroughly practical means for operating and controlling the action of the motors. The regulating apparatus is simple in construction and operation and not easily put out of order to give trouble in use. The greatest tractive effort is obtained when the rheostat has been cut out of circuit altogether, thus giving the field magnets their full strength. The increase of effect so obtained reacts upon the armature and causes it to turn with a greater torque and enables the car to do very heavy work; in some cases

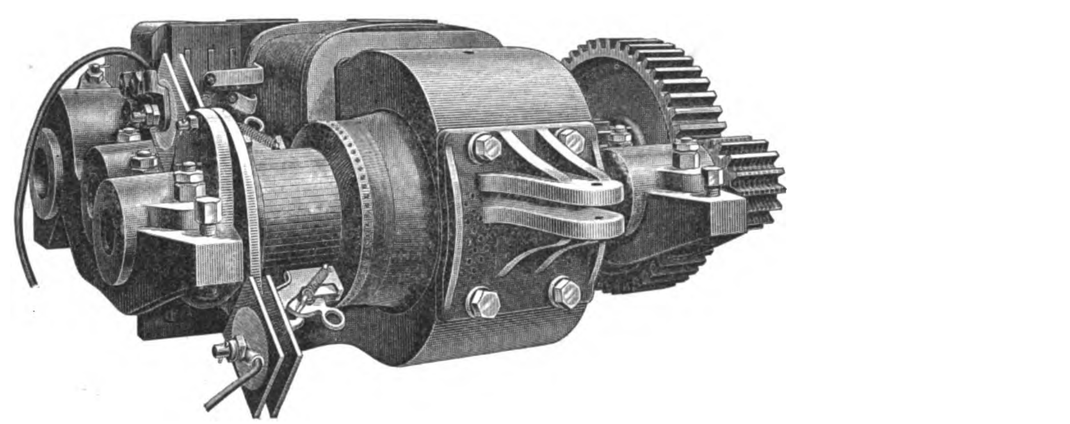

FIG. 8.—Thomson-Houston Railway Motor.

the motor car being used as a towing car for one or more other cars unprovided with electric motor appliances. There are two cut-off switches placed on each car, one at each end, whereby the entire current may be shut off instantly from the motor mechanism in case of accident.

Of the twelve Van Depoele roads in operation when the Thomson-Houston company took over the Van Depoele patents and business, several have been converted to the present Thomson-Houston system. The demand for electric railway outfit has developed so rapidly during the last year that the Thomson-Houston company, notwithstanding its extensive manufacturing capacity, has found it difficult to supply apparatus fast enough, and has found it necessary to increase its facilities by building new factories and shops, and it is utilizing to the utmost such increased facilities.

THE STRENGTH OF THE INDUCED CURRENT WITH A MAGNETO-TELEPHONE TRANSMITTER AS INFLUENCED BY THE STRENGTH OF THE MAGNET.[1]

BY CHARLES R. CROSS AND ARTHUR S. WILLIAMS.

It is a well-known fact in practice, as well as an evident consequence of theoretical considerations, that the effectiveness of a magneto telephone when used either as a transmitter or as a receiver varies with the strength of the magnetism of the core. But the relation of the one to the other has never been studied, so far as we are aware.

Our investigations include a study of the changes in strength of the current produced by a magneto transmitter under varying conditions of magnetization, and of the magnitude of the momentary changes in the magnetic condition of the core of the receiving telephone when subjected to the action of undulatory or other brief currents, as influenced by the strength of the primitive permanent magnetization of the core. The present paper contains only the results of a series of experiments relating to the first of these, that is, to the effect of varying strength in the magnet of the transmitter, the study of the allied problem of the receiver being still in progress.

The apparatus employed consisted of a cylindrical bar of soft iron about 4½ inches in length and one-quarter of an inch in diameter, around one end of which was placed a coil of fine wire similar to that used in ordinary telephonic practice. The resistance of this coil was 100 ohms. It was placed in circuit with a ballistic mirror galvanometer, from whose deflection the momentary current produced in the coil by any variation in the strength of the core could be determined. The diaphragm, which was in all cases 2 5/16 inches in diameter, was in its usual place opposite the end of the magnet about which the wire coil was wound, and about 8/100th of an inch from that end. By means of a rod carrying a cam moved by a weight, a rapid inward push of definite amount was given to the diaphragm, thereby inducing a current in the coil already referred to, and so deflecting the needle of the ballistic galvanometer. The soft iron bar was also surrounded by a second helix, through which was passed a current from a storage battery, serving to magnetize the core. A tangent galvanometer inserted in this circuit gave the strength of the magnetizing current. A magnetometer placed in the prolongation of the axis of the core, which last occupied an east and west position, made known the relative strengths of the field produced by the core under different conditions of magnetization.

Corresponding observations of the magnetometer reading, and of the current induced when the diaphragm was moved by the cam, were made throughout a widely varying range of strength of field, and the results were represented graphically by constructing a series of curves in which ordinates represent the relative strength of field, and abscissas the current due to a given predetermined throw of the diaphragm (about 1/100th of an inch), as ascertained from the readings of the ballistic galvanometer.

One of these curves is shown at 1, figure 1, the core in this case being a cylindrical bar of Norway iron 4½ inches long and one-quarter of an inch in diameter, and the diaphragm an ordinary disc of ferrotype iron 2 5/16 inches in diameter and 1/100 of an inch thick (No. 31 B. W. G.).

Table i. gives the data from which figure 1 was constructed. The strength of field is given in terms of the tangents of the angles of deflection of the magnetometer needle. The induced current is given in arbitrary units, as only relative values are needed. A determination of the value of the deflections was made by observing the excursion due to the discharge of a condenser through the ballistic galvanometer, and it was found that the abscissa 100 on the curves corresponds to a sudden discharge of approximately 0.00000097 of a coulomb through the coils of the galvanometer.

An examination of figure 1, as well as of the various curves following it, will show that the effect of increasing the strength of the magnet of the transmitter is in all cases to cause at first a rather rapid increase of the strength of the induced current, which later increases less rapidly, rising soon to a maximum value, from which it falls off, at first rapidly, and afterwards more and more slowly as the strength of the field is further increased. We proceed to consider the explanation of these results.

1. From the Proceedings of the American Academy of Arts and Sciences. Presented November 14, 1888.

It is evident that three distinct sources of variation exist to affect the current furnished by a magneto transmitter as the strength of the magnet is increased. First, the direct effect of the increased strength of field in which the diaphragm moves is to increase proportionally the strength of the induced current, since it increases correspondingly the rate of change in the number of lines of force enclosed by the coil of the instrument; second, an approach toward saturation of the magnet, so far as it alone is concerned, will tend to diminish the induced current, on account of the smaller variation in the strength of the pole due to a given motion of the diaphragm; and, third, the nearer approach toward saturation of the diaphragm will have the same tendency.

The rapid rise in the induced current at the beginning is of course due to the predominating influence of the increasing strength of the field in which the diaphragm moves, as both core and diaphragm are then but slightly magnetized. The subsequent changes in the current must be explained by a consideration of the increasing magnetization of either the core or the diaphragm, or both.

It will be seen by comparing tables i., ii., and iii., that the value of the maximum induced current for a given excursion of the diaphragm is approximately the same with all the three cores used, and that the same is true as to the strength of field corresponding to this maximum current. Moreover, saturation curves constructed for the several cores showed that in all cases the magnet was still very far removed even from half-saturation when the maximum induced current was obtained. From these facts it appears that the degree of saturation of the magnet is practically unimportant, so far as the general results shown in figure 1, are concerned.

It remains to observe the part played by the increasing magnetization of the diaphragm. Other things remaining the same, as this approaches more and more closely towards saturation the increase in the number of lines of force passing between it and the magnet on the approach of the diaphragm to the magnet must become smaller and smaller, and this change will tend to oppose the effect of the increased absolute strength of the magnetizing force. The small mass of diaphragm will evidently cause it to show the effect of an approach to saturation, while the core is far below that condition. And such an action will clearly explain the observed changes in the current strength.

In order to test this matter still further, the experiment was tried of varying the mass and material of the diaphragm.

The results are shown by the curves in figures 1, 2, and 3, which are constructed from the data given in tables i. to x.; further results of the same character are given in tables xi. and xii.

Curve 2, figure 1, represents the results when two of the ordinary ferrotype diaphragms were superposed, forming a diaphragm of double thickness, and curve 3 of the same figure shows the results when three such diaphragms were superposed. Each diaphragm was 0.01 of an inch thick. The curves of figure 2, marked 21, 22, 23, respectively, show the results of similar experiments with diaphragms of sheet iron whose thickness was 0.030, 0.027, 0.024 of an inch, respectively (Nos. 21, 22, 23, B. W. G.). Figure 3 shows the results when a steel diaphragm 0.017 of an inch thick (No. 26) was used, the curve U being that for untempered steel, and T that for tempered steel. Steel diaphragms respectively 0.026 and 0.012 of an inch thick (Nos. 22 and 30) gave similar results, as will be seen from tables xi., xii., and xiii.

An inspection of these curves shows immediately that the greater the strength of the field required to saturate the diaphragm, the greater is the strength of the field at which the maximum current occurs. Thus in figure 1 the maximum current with curve 1 corresponds to a strength of field of about 12 units of the scale used, while with curves 2 and 3 the corresponding strengths of field are 20 and 43 units respectively. Also in figure 2 the maximum currents will be seen to correspond to greater strengths of field in proportion to the thickness of the diaphragm, and in figure 3 similar though less marked results hold for tempered as compared with untempered steel of the same thickness.

It would also be expected that the value of the maximum current would be greater with a thick than with a thin diaphragm. This was usually the case in our experiments. Thus the curves 1, 2, 3, of figure 1 give maximum currents of 27.5, 50.2, and 62.6 units respectively. Results of a similar nature are shown by figure 3, the maximum current with the untempered diaphragm being far greater than with the tempered one. Curve No. 23 of figure 2 is apparently an exception. It is probable, however, that this is in appearance only, and that the three curves of that figure are not strictly comparable with one another. The rigidity of the diaphragms here used, especially of the thicker ones, is considerable, and any slight yielding of the supports of the rod which carried the cam would prevent the actual throw of the diaphragm from being as great when this had considerable thickness, and would greatly diminish the strength of the current produced.

The peculiarity of curve 2, as compared with 1 and 3, is probably caused by the want of both magnetic and mechanical continuity in the material of the multiple plate formed by the several diaphragms used.

In those cases where steel diaphragms were employed, there was always a notable induced current, even when the reading of the magnetometer was zero. This was probably due to a slight residual magnetization of the diaphragms.

The results stated in this paper may serve to explain a phenomenon which has seemed somewhat obscure. Frequent attempts have been made to increase the efficiency of a magneto transmitter by polarizing the diaphragm as well as the magnet, a common way of doing this being to employ a horseshoe magnet one leg of which is in contact with the edge of the diaphragm, while the other, about which the coil is wound, is placed in its usual position opposite the centre. But as a general rule little or no gain has seemed to result therefrom, so far as can be judged by the performance of such instruments in actual practice. It is quite probable in this case that the increased approach to saturation of the diaphragm may have so great an effect as entirely to prevent the expected improvement.

It will also be seen from our results, that an increase in the thickness of the diaphragm of a magneto transmitter tends to allow of the use of a stronger magnet, and for a given amplitude of vibration to produce a stronger current. But it must be remembered, on the other hand, that the greater rigidity of the thick diaphragm will diminish this range of vibration under the action of the voice, a difficulty which may to a certain extent be remedied by using a diaphragm of large diameter.

Rogers' Laboratory of Physics,
October, 1888.

ARC LAMPS AND THEIR MECHANISM.[1]

BY PROFESSOR SILVANUS THOMPSON, D. SC., M. I. E. E.

An arc lamp being an apparatus for transforming the electric energy supplied to it through the conducting wires into heat and light, it obviously cannot be expected to give a steady illumination unless it can be so arranged and operated that, in the first place, the rate at which it appropriates and transforms the electric energy is constant, and that, in the second place, the circumstances attending this transformation (in respect of the triple relation between the quantity of heat evolved, the degree of temperature, and the emissivity of the incandescent surface), also remain constant. The first of these two provisos relates to the operation of the system of lamps and dynamos (or other means of electric supply) acting conjointly; the second of them relates solely to the quality of the carbon pencils used as electrodes.

As the latter is a simple matter, it may be disposed of first. Suppose the pencils to be composed of a homogeneous carbon, the physical properties of which, such as hardness, specific thermal capacity, conductivity for electricity, conductivity for heat, emissivity, etc., are constant; also that they are cylindrical and of given diameter. Then it follows that if energy is being expended at a uniform rate in heating the tips of a pencil it will be maintained at a uniform temperature, and the amount of light emitted per square millimeter of the surface will be constant, and, as the section is constant, the rate of consumption constant, and the pencil homogeneous, the form once acquired by the incandescent tip (whether positive crater or negative peak) will remain constant. It may be remarked, in passing, that the researches of Captain Abney have shown that the white light of the incandescent carbon surface of the crater at the positive pole of the arc is always of precisely the same composition in respect to the relative proportions of waves of different colors. This most important observation indicates beyond doubt that the temperature of the actual light-emitting surface is always the same. Indeed, this ought to be the case if the latent heat of vaporization of carbon be a positive quantity. When the surface attains this temperature, volatilization begins; and when so begun the temperature cannot rise further, any more than ice can be raised above its temperature of fusion. The limiting temperature of the voltaic arc is the temperature of volatilization of the material of the electrodes. This is, in itself, a reason why the introduction of all known foreign substances whatsoever into the carbon pencils of the arc is found to lower its intrinsic brilliancy; for all known elements have a lower temperature of volatilization, and all compounds are dissociated at arc temperatures.

If, then, we may assume homogeneity of the carbons to be used, the steadiness of the arc light will depend solely upon the maintenance of a steady rate of appropriating and transforming electric energy. How a want of homogeneity may be compensated for in the actual working of the lamp is a point reserved for consideration later.

The rate at which electric energy is appropriated from the wires, and transformed in the lamp into heat and light, always depends both upon the construction of the lamp and upon the conditions imposed upon the system of electric supply. This is a mere consequence of the fact, well known to every electric engineer, that the amount of electric energy per second appropriated by any electric device, motor, or accumulator, is itself the product of two quantities—the current and the pressure (or potential) at which

1. Paper read before The Society of Arts, London, March 6, 1889.

the current is supplied. To put the matter in electricians' language, the number of *watts* of electric energy per second appropriated by the lamp[2] is equal to the number of *amperes* that flow through it multiplied by the number of *volts* that may be applied as a difference of potentials between its two terminals. To keep constant the *product* of the amperes and the volts is the practical problem which the mechanism of the arc lamp must be designed to solve.

A point of much theoretical interest, and in reality of great practical importance, is the fact, long disputed, now established beyond question, that the arc itself does not act simply as an added resistance in the path of the current, but exercises also a counter electromotive force, and tends to set up an opposing current. The apparent resistance of the arc resembles that of an electrolytic cell, or that of an electric motor when running, or, that of a thermopile when a current from an external source is passed through it. The current which flows through the arc arouses, by a species of polarization, an opposing electromotive force. The simplest fact in proof of this is that, unlike any ordinary conductor, the apparent resistance of the arc is not proportional to its length. The apparent resistance of an arc two millimeters in length between the carbon tips is not double that of an arc one millimeter in length, nor anything near double. The fairest way to investigate the matter is to make a series of experiments with arcs of different lengths, the current being independently so regulated as to be maintained of the same strength in each case. There appears to be a true resistance proportional to the length, and a back electromotive force which in steady arcs, and with currents of from seven to fifteen amperes, appears to be about thirty-eight to thirty-nine volts. When the arc hisses, as often happens if the length of it be very short, the back electromotive force fluctuates very much, but always drops to something under twenty volts. Except in the case of constant current circuits, this causes a sudden increase of current when the lamp begins to hiss, and it may be noticed that the light, though unsteady during hissing, is brighter at the negative pole of the arc.

Hitherto, all guesses as to the cause of this counter-electromotive force have been very vague, not to say wild. To account for thirty-nine volts of polarization on any hypothesis that it is due to electrolytic or thermo-electric action, is to suggest causes which are, to say the least, wholly inadequate. The explanation which for the past two years I have been in the habit of suggesting to my students, and which has not been otherwise published hitherto, is as follows:—Every reversible phenomenon which the current can itself produce, and which requires an expenditure of energy for its production, necessarily implies the exhibition of a counter electromotive force. One has only to look at the cases of the reversible chemical action in a cell, of the reversible magneto-mechanical action of a motor, the reversible heating effects of a thermo-electric junction, to comprehend this. Now the phenomenon of volatilization is a reversible one: give to the solid carbon at its volatilization-temperature the necessary latent heat, it is changed to vapor; take from the vapor its latent heat, it condenses back to solid carbon. The arc under normal circumstances is the seat of an actual evaporation of carbon at the positive pole, as well as of a combustion at both poles. So far as any data exist, it appears that the excess of carbon consumed at the positive pole by an ordinary continuous current, is about 0.5 grammes per ampere-hour. if we knew the latent heat of volatilization of carbon per gramme we could calculate *a priori* the necessary minimum electromotive force at the positive pole, which would obviously represent the counter electromotive force so far as it is situated at that point. With long arcs the excess of consumption of the positive pencil over that of the negative is both less and more regular than that which occurs with short arcs. With short arcs three other phenomena occur, which are important in this connection. Firstly, the short arc is liable to whistle or hiss, giving evidence of instability; secondly, it frequently gives rise to "mushrooms," or irregular growths of carbon upon the apex of the negative pencil; thirdly, when it hisses the counter-electromotive force becomes very unsteady, but appears to have an average value about half that of the steady long arc. It is worth while to throw out the suggestion, that the condensation of carbon at the negative pole, in the short arc, is accountable for the change in electromotive force, and for the instability which manifests itself by the hissing sound.

Passing from these conjectures to the construction of lamps for the production of light by the arc, we are now prepared to lay down the points which must be provided for in every arc lamp. It must be emphatically pointed out at the outset that, as a performance of a lamp depends upon the conditions under which it is supplied with electric energy by the circuit, the design of the lamp necessarily also depends on those conditions. In the present state of the art of electric distribution we may classify the conditions of electric supply under the following heads:—

I.—CONTINUOUS SUPPLY AT CONSTANT POTENTIAL.

In this case the arc lamps are arranged either simply all in parallel or in parallels containing two in series; the currents being divided by mains and branches to the lamps. At least 55 volts should be allowed between the mains for single arcs. Practice shows that arc lamps in parallel burn more steadily if a resistance wire of .25 to 1.0 ohm be included in the lamp circuit. Taking the back electromotive force of a steady arc at 39 volts, it is obvious that the excess of the volts at the mains over this represents the volts used in driving the current through the actual resistance in the main circuit of the lamp. This resistance consists of four parts—the true resistance of the arc itself, which may vary from $\frac{1}{10}$ to $\frac{1}{2}$ ohm; the resistance of the carbon pencils, which averages about 0.15 ohm per foot per plain carbons; the resistance of the main circuit coils, which varies in different lamps from 0.05 to 0.2 ohm; and the resistance of the wire introduced for steadying the lamp. In a 10-ampere lamp, working at 55 volts at the mains, 16 volts remain after deducting 39 for the back electromotive force, and these 16 are approximately distributed as follows:—2 volts in the arc itself, 3 volts in the carbons (say 2 feet long in the total), 1 volt in the main coil, and 10 volts in the steadying resistance.

2. Strictly speaking, the actual number of *watts* utilized in the arc is somewhat less than the whole number received from the supply, as a portion of the energy is expended in passing the current through the regulating coils, and another portion is lost in consequence of the resistance offered by the pencils of carbon themselves, and is merely expended in warming them. We may calculate the former loss as follows:—Let E represent the whole number of volts from terminal to terminal, and let i represent the whole current supplied, then the whole number of watts supplied is Ei. Let the *ohms* of resistance of the regulating coils in the main circuit be called a, and that of the shunt coils be called b, that of the carbon pencils themselves c, and that of the resistance coils sometimes used in the main circuit to steady the arc, r. Also, in the case where the lamp has a shunt circuit, let the portion of i which passes through the carbons be called i_1, and that which goes through the shunt, i^2; so that $i_1 + i_2 = i$. The losses are then as follows:—

$$ai_1^2 = \text{watts lost in main circuit coil;}$$
$$bi^2 = E^2 + b = \text{watts lost in shunt coil;}$$
$$ci_2^1 = \text{watts lost in warming carbon pencil;}$$
$$ri^2 = \text{watts lost in the resistance coil.}$$

The resistance of carbon pencils is usually small, and may be materially reduced by a thin coating of copper. The carbons used in commerce (11 to 15 millimeters in diameter) vary from about 0.15 to 0.2 ohms per foot, if plain, and from 0.001 to 0.09 if coppered. Cored carbons have a higher resistance than uncored. Carbons cut from solid gas coke have from five to twenty times as much resistance as those made by the usual modern processes. When lamps are run in series, the resistance offered by the pencils is of more importance; for example, a set of 50 lamps newly trimmed with long carbons may offer 25 ohms more resistance than when all the carbons have burned down short. The resistance, a, of the regulating coils that are in the main circuit differs in different lamps, but may be taken at from 0.05 to 0.2 ohms. The resistance, b, of the shunt coils, is seldom less than 200 ohms, and may be as much as from 400 to 500 ohms. Of the volts, E, applied to the lamp, only a part is utilized, the lost volts being accounted for by the resistances in the path of the current. If these are deducted from the applied electromotive force, there will remain a certain number of volts, which we may call e, which are available as a useful difference of potential at the arc itself. To measure e directly, one has only to apply a voltmeter, making the contacts of its two leading wires to the two carbons at points respectively just above and just below the incandescent tips. The watts actually utilized in the arc are then calculated as the product ei_1. As shown above, e is less than E, and, indeed, may be considerably less, the lost volts depending upon the resistances introduced, and on the current flowing through them. If E is constant, e will not necessarily be so, but will be very nearly if i is also constant. Also i_1 is less than i in all lamps that have a shunt regulating coil, but is not usually more than from 3 to 5 per cent less than i, so that in the cases where i is kept constant, i_1 will be nearly so also.

II.—CONTINUOUS SUPPLY WITH CONSTANT CURRENT.

In this case the arc lamps are arranged in series, the whole of the current going from one lamp to the next, and returning to the dynamo after having traversed successively all the lamps. This is, *par excellence*, the arc light system of distribution, the parallel system at constant potential requiring heavier mains. As the lamps arranged in series tend to steady one another, it is not necessary to allow more than 45 to 50 volts per lamp, including the ordinary lengths of cable from lamp to lamp. From 5 to 10 amperes is the usual current for arc lamps in series.

III.—ALTERNATING SUPPLY AT CONSTANT POTENTIAL.

In this case, also, the lamps are usually arranged as in the first case, the only difference being in certain structural details, such as lamination of iron cores.

IV.—ALTERNATING SUPPLY WITH CONSTANT CURRENT.

This case can hardly be said to be practical, though alternate current dynamos, capable of supplying 6 or 8 lamps in series, have been constructed in past years.

The supply systems, whether continuous or alternating, must be assumed, for the purpose of this paper, to perform efficiently what they profess, namely, to maintain constant one of the two factors of the electric power which they supply to the distributing system. In each case it remains for the mechanism of the lamp to effect such adjustment as will maintain constant the other factor of the product. If the condition of supply is "at constant potential," then it is for the lamp itself so to adjust its carbons as to keep the current through the arc constant. If the condition of supply is "with constant current," then the lamp must adjust its carbons to maintain between them the requisite potential. Hence the differences which are necessary in construction between those lamps which are to work "at constant potential" (in parallel) and those which are to work with constant current (in series). These differences, as will now be shown, chiefly affect the "feeding" mechanisms of the lamp.

In discussing the necessary mechanisms of arc lamps, no further reference will be made to lamps of the Jablochkoff candle type, nor to those with abutment blocks of marble ("Sun" lamp, etc.), nor to the so-called incandescence arc ("Semi-incandescent") lamps, nor to those with curved carbons (Heinrichs's type), nor yet to those horizontal carbons (De Mersanne's, Solignac's, etc.).

NECESSARY MECHANISM OF ARC LAMPS.

[A.] *Driving power.*—In every lamp some means or mechanism is required to propel the carbons toward one another as they burn away, gravity being by far the most common agency for doing this.

[B.] *Striking mechanism.*—In every arc lamp it is requisite to provide a mechanism for bringing the tips of the carbon pencils into contact, and then parting them asunder to the requisite distance across which the arc or flame plays. If, as in most lamps, the carbons are in contact when the lamp is out of action, then a mechanism is required simply to part them as soon as the current is turned on. The operation of producing the arc by parting the carbons is known as "striking" the arc. The mechanism must be automatic, so as to come into action not only when the current is first turned on, but at any subsequent time if from any cause the arc fails. An adjustment, *b*, of the striking mechanism is also usually added to permit of regulation in the length of the stroke or initial distance between the poles.

[C.] *Feeding mechanism.*—As the carbons burn away, one or both of them must be propelled forward to maintain the arc at its proper size. This action is called "feeding" the arc. This action ought to take place by small and imperceptible amounts, and as the rate of consumption of the carbons is continually varying, even with carbons of the best modern manufacture, the lamp must itself regulate the rate at which the pencils are propelled forward in automatic correspondence with the consumption for the time being. Further, since the presence of soft and more readily volatilized portions in the pencils seems to be unavoidable, provision ought to be made so that, whenever the pencil burns down to such a portion, causing a sudden increase in the volume of the flame or arc—technically called a "blower"—the mechanism of the lamp ought at once automatically to draw apart the pencils to a slightly greater distance. A lamp which has a *retractile* motion in either its feeding or its striking mechanism is superior to one that has not, as it can be used with cheaper and less pure brands of carbons. An adjustment, *c*, for regulating the frequency or range of the feeding movements is usual.

[D.] *Replacement mechanism.*—When the pair of carbon pencils has burned away, the lamp trimmer has to replace the stumps by a new pair of long carbons. In order to admit these, the carbon holders must be pushed apart to their widest extent. Special mechanical devices for allowing this motion to occur have to be provided in some forms of lamp, whilst other forms need no special device.

[E.] *Moderating mechanism.*—To prevent the carbon from making too sudden motions, it is usual to add a moderating device, such as a dash-pot, or, in the case of those lamps in which there is a train of wheels, a fan or a governor.

So far, the devices enumerated have been such as are common to all classes of lamps. Those which follow are only required in particular types of lamp.

[F.] *Focusing mechanism.*—In all those cases where it is desired that the luminous points should occupy a fixed position in space, some additional mechanism is necessary to make the arc lamp keep its focus. In lamps designed for the mere lighting of area, this is not important, and in the vast majority of these the upper carbon descends whilst the lower carbon (the negative) is fixed; the luminous point slowly shifting downwards as the carbons consume. All devices for causing the carbons to move forward at such relative rates as to keep an approximately fixed position for the arc will be discussed, together with their methods of adjustment, *f*, under the heading of focusing mechanism.

[G.] *Change-over mechanism.*—Lamps that must run for many hours continuously must be supplied with two pairs of pencils, because it is neither practicable nor advisable to use pencils of extreme length. In the double lamps it is appropriate to provide such arrangements as shall cause one pair of pencils to come into operation first, and when these are consumed away, shall change over the action, either by electrical or by mechanical devices, so that the second pair of pencils shall come into operation.

[H.] *Cut-out mechanism.*—Lamps intended for series working must be provided with some contrivance to prevent the extinction of the whole series when from any cause there is a failure of the light in any one lamp. The usual device is a sort of automatic relay arranged in connection with each lamp, to come into operation in the event of its failure, the operation of the device being (1) to cut the faulty lamp out of circuit by simply short-circuiting it, or (2) to substitute for it a wire of suitable resistance, or (3) to replace it by an auxiliary lamp. The device for performing either of the two former operations is technically known as a "cut-out."

SUPPLEMENTARY CONTRIVANCES.

In addition to the eight distinct species of contrivances above enumerated, there are numerous details which might be further classified; such, for example, as devices for *clamping* the carbon pencils to their respective holders in true allignment; devices for raising and lowering the lamps. For these, however, there is no space. Neither is it possible to enumerate the devices which have been sug-

gested [Staite, Siemens, Brockie, Andrews, Crompton, Swinburne, and others] for *compensating*, in lamps whose action depends on the weight of the descending carbon pencil and its holder, for the diminution of pull as the pencil is consumed.

SCHEDULE OF MECHANISMS.

A schedule embracing the eight heads above enumerated, if supplemented by statements of the gauges and resistance of the wires used in the winding of the coils, affords a systematic and very convenient method of tabulating the facts concerning the construction of any arc lamp. An example of such schedule, filled up with the data of one arc lamp of recent pattern, is given at the end of this paper.

ELECTRO-MAGNETS FOR ARC LAMPS.

As the electro-magnet plays so essential a part in the striking, feeding, and cut-out mechanisms of lamps, a short digression upon the particular forms of electro-magnets appropriate to arc lamps is not out of place. The ordinary treatises on electricity have little to tell about the special properties of different forms of electro-magnet; indeed, this all-important organ in modern electrical engineering has received very inadequate attention from writers on electricity. It is a familiar fact that the attraction of a horseshoe-shaped magnet, whether of steel or iron, varies very greatly with the position of the iron armature, being great at small distances, but very rapidly falling away as the intervening space is increased. To devise a form of electro-magnet whose attractive power shall be exerted over a fairly long range was at one time one of the practical problems of electricians, and it has been solved in various ways. The attraction which a solenoid, or tubular coil, exerts, when traversed by a current, upon an iron core introduced within its aperture, is not, in any position of the core, nearly as great as that exercised by an electro-magnet of horseshoe type, constructed of equal amounts of metal, and energized by an equal current. On the other hand, the feebler pull of the solenoid upon its core is exerted through a very extended range. And by making the core of conical form, or by winding the coils of the solenoid in a conical fashion, it is possible still more completely to equalize the pull over a long range. Solenoids with cores are used in several well-known types of lamps in which a long travel is required. On the other hand, since the operation of striking the arc requires a short motion not exceeding one-twelfth of an inch, or two millimeters, in all those types of lamp in which a special electro-magnet is used simply to strike the arc, a form of electro-magnet is required which will exert a powerful pull over a short range. Further, for working certain clutch mechanisms and the like, it is desirable that a form of electro-magnet should be found which, whilst having a travel of, say one inch, should exert throughout the whole of that range a fairly strong pull, increasing of course toward the end. Experiments show that the special forms of electro-magnets may be tabulated as follows :—

(*a*) *Short-range magnets.*—1. Horseshoe form, if constructed with short thick cores, thick yoke and thick armature, giving compact magnetic circuit.

2. "Pot-magnet," straight core with external tubular envelope, connected by iron at bottom. Armature, a stout iron disc or lid.

(*b*) *Moderate-range magnets.*—1. Horseshoe form with long thin cores and armature, giving a non-compact circuit.

2. Solenoid having a short fixed core extending part of the way down, and a second movable core to be attracted in as plunger. The name "stopped solenoid" is suggested as appropriate for this form.

3. Two such as last, having a yoke connecting the two fixed cores, and a second yoke connecting movable cores.

4. Stopped solenoid with plunger attached to an outer mantle [Kennedy's lamp, figure 10].

5. Electro-magnet with conical poles protruding through hollow in armature [Thomson-Houston lamps, figures 14 and 25].

6. Electro-magnets with oblique approach of armature. [Serrin's, figure 5; De Puydt's, figure 23; and many other lamps.]

(*c*) *Long-range magnets* —1. Solenoid, cylindrical, with longer cylindrical core. Attraction greatest when entrant end of core just reaches the further side.

2. Solenoid, cylindrical, with long coned core entering with the point foremost.

3. Solenoid, conical, with long cylindrical core entering the thicker end of solenoid.

4. Special device for travel of unlimited length. A solenoid constructed in sections, which are switched into circuit progressively ahead of the core as the core travels down[3] [Thomas, 578[82]; Lindemann, 16,376[87]].

It must be borne in mind that the range of an electro-magnet depends on the relative dispositions of the iron parts of the magnetic circuit and of the magnetizing copper parts, and in no way upon the question whether the coil consists of a few turns of thick wire, or of many turns of thin wire.

(*To be continued.*)

HERTZ'S RESEARCHES ON ELECTRICAL OSCILLATIONS.[1]

BY G. W. DE TUNZELMANN, B. SC.

(Continued from page 172.)

Dr. Hertz was at first inclined to suppose that as the micrometer circuit was only broken by the extremely short air space limited by the maximum sparking distance under the conditions of the experiment, it might therefore be treated as a closed circuit, and only the total induction considered. The ordinary methods of electro-dynamics give the means of completely determining the total inductive effect of a current element on a closed circuit, and would, therefore, in this case have sufficed for the investigation of the phenomena observed. He found, however, that the treatment of the micrometer circuit as a closed circuit led to incorrect results, so that it, as well as the primary, had to be treated as an open circuit, and, therefore, a knowledge of the total induction was insufficient, and it became necessary to consider the value both of the E. M. F. induction and of the electrostatic E. M. F. due to the charged extremities of the exciting circuit at each point of the micrometer circuit.

The investigations to which these considerations led are described by Dr. Hertz in a paper "On the Action of a Rectilinear Electrical Oscillation upon a Circuit in its Vicinity," published in Wiedemann's *Annalen*, vol. xxxiv., p. 155, 1888.

In what follows, the exciting circuit will be spoken of as the primary, and the micrometer circuit as the secondary. Hertz points out that the reason that the electrostatic effect cannot be neglected is to be found in the extreme rapidity with which the electrostatic forces change their sign. If the electrostatic alternations in the primary were comparatively slow they might attain a very high intensity without giving rise to a spark in the secondary, since the electrostatic distribution on the secondary would vary so as to remain in equilibrium with the external E. M. F. This, however, is impossible, because the variations in direction follow each other too rapidly for the distribution to follow them.

In the present investigations the primary circuit consisted of a straight copper wire five millimeters in diameter, carrying at its extremities hollow zinc spheres 30

3. Figures in square brackets relate to patent specification or date.

1. From the *Electrician* (London).

centimeters in diameter. The centres of the spheres were one meter apart, and at the middle of the wire was an air space $\frac{3}{4}$ centimeter in length. The wire was placed in a horizontal position, and the observations were all made at points near to the horizontal plane through it, which, however, did not, of course, affect their generality, as the same effects would necessarily be produced in any plane through the horizontal wire. The secondary circuit consisted of a circle of 35 centimeters radius of copper wire two millimeters in diameter, the circle being broken by an air space capable of variation by means of a micrometer screw.

The circular form was selected for the secondary circuit because the former investigations had shown that the sparking distance was not the same at all points of the secondary, even when the conductor as a whole remained unchanged in position, and with a circular circuit it was easier to bring the air space to any part than if any other form had been used. To attain this object the circle was made movable about an axis passing through its centre perpendicular to its plane.

The circuits of the dimensions stated were very nearly in unison, and they were further adjusted by means of little strips of metal soldered to the extremities, and varied in length until the maximum sparking distance was obtained.

We shall follow Dr. Hertz in first considering the subject theoretically, and then examining how far the experimental results are in accordance with the theoretical conclusions. It will be assumed that the E. M. F. at every point is a simple harmonic function of the time, but that it does not undergo reversal in direction, and it will further be assumed that the oscillations are at any given moment everywhere in the same phase. This will certainly be the case in the immediate neigborhood of the primary, and for the present we shall confine our attention to such points. Let s be the distance of a point, measured along the circuit from the air space of the secondary, and F the component E. M. F. at that point along the circular arc $d\,s$. Then F is a function of s, which assumes its original value after passing once round the circle of circumference S. It may, therefore, be expanded in the form

$$F = A + B \cos\frac{2\,\pi\,s}{S} \ldots\ldots + B' \sin\frac{2\,\pi\,s}{S} + \ldots\ldots$$

The higher terms of the series may be neglected, as the only result of so doing will be that the approximate theory will give an absolute disappearance of sparks where really the disappearance is not quite complete, and indeed the experiments are not delicate enough to enable us to compare their results with theory beyond a first approximation.

The force A acts in the same direction, and is of constant amount at all points of the circle, and therefore it must be independent of the electrostatic E. M. F., as the integral of the latter round the circle is zero. A then, represents the total E. M. F. of induction, which is measured by the rate of variation of the number of magnetic lines of force which pass through the circle. If the electromagnetic field containing the circle is assumed to be uniform, A will therefore be proportional to the component of the magnetic induction perpendicular to the plane of the secondary. It will therefore vanish when the direction of the magnetic induction lies in the plane of the secondary. A will consist of an oscillation, the intensity of which is independent of the position of the air space in the circle, and the corresponding sparking distance will be called a.

The term $B' \sin\frac{2\,\pi\,s}{S}$ can have no effect in exciting the fundamental vibration of the secondary, since it is symmetrical on opposite sides of the air space.

The term $B \cos\frac{2\,\pi\,s}{S}$ will give a force acting in the same direction in the two quadrants opposed to the air space, and will excite the fundamental vibration. In the two quadrants adjacent to the air space it will give a force in the opposite direction, but its effect will be less than that of the former one. For the current is zero at the extremities of the circuit, and therefore the electricity cannot move so freely as near the centre. This corresponds to the fact that if a string fastened at each end has its central portion and ends acted on respectively by oppositely directed forces, its motion will be that due to the force at the central portion, which will excite the fundamental vibration if its oscillations are in unison with the latter. The intensity of the vibration will be proportional to B. Let E be the total E. M. F. in the uniform field of the secondary, φ the angle between its direction and the plane of the latter, θ the angle which its projection on this plane makes with the radius drawn to the air space. Then we shall have approximately

$$F = E \cos \varphi \sin\left(\frac{2\,\pi\,s}{S} - \theta\right),$$

and, therefore, $B = -E \cos \varphi \sin \theta$.

B, therefore, is a function simply of the total E. M. F. due both to the electrostatic and electro-dynamic actions. It will vanish when $\varphi = 90°$—that is to say, when the total E. M. F. is perpendicular to the plane of the circle, whatever be the position of the air space on the circle. B will also vanish when $\theta = 0$—that is to say, when the projection of the E. M. F. on the plane of the circle coincides with the radius through the air space. If the position of the air space on the circle is varied, the angle θ will vary, and, therefore, also the intensity of the vibration and the sparking distance. The sparking distance corresponding to the second term of the expansion for F can, therefore, be represented approximately by a formula of the form $\beta \sin \theta$.

Now the oscillations giving rise to sparks of lengths a and $\beta \sin \theta$ respectively are in the same phase. The resulting oscillations will therefore be in the same phase, and their amplitudes must be added together. The sparking distance being approximately proportional to the maximum total amplitude may therefore also be obtained by adding the sparking distances due to the two oscillations respectively. The sparking distance will therefore be given as a function of the position of the air space on the secondary circuit by the expression $a + \beta \sin \theta$. Since the direction of the oscillation in the air space does not come into consideration we are concerned only with the absolute value of this expression, and not with its sign. The determination of the absolute values of the quantities a and β would involve elaborate theoretical investigations, and is, moreover, unnecessary for the explanation of the experimental results.

Experiments with the secondary circuit in a vertical plane.—When the circle forming the secondary circuit was placed with its plane vertical, anywhere in the neighborhood of the primary, the following results were obtained:—

The sparks disappeared for two positions of the air space, separated by 1·0°, namely, those in which it lay in the horizontal plane through the primary; but in every other position sparks of greater or less length were observed.

From this it followed that the value of a must have been constantly zero, and that θ was zero when the air space was in the horizontal plane through the primary.

The electro-magnetic lines of force must therefore have been perpendicular to this horizontal plane, and therefore consisted of circles with their centres on the primary, while the electrostatic lines of force must have been entirely in the horizontal plane, and therefore this system of lines of force consisted of curves lying in planes passing through the primary. Both of these results are in agreement with theory.

When the air space was at its greatest distance from the plane the sparking distance attained a maximum value of

from two to three millimeters. The sparks were shown to be due to the fundamental vibration, by slightly varying the secondary, so as to throw it out of unison with the primary, when the sparking distance was diminished, which would not have been the case if the sparks had been due to overtones. Moreover, the sparks disappeared when the secondary was cut at its points of intersection with the horizontal plane through the primary, though these would be nodal points for the first overtone.

When the air space was kept at its greatest possible distance from the horizontal plane through the primary, and turned about a vertical axis, the sparking distance attained two maxima at the points for which $\varphi = 0$, and almost disappeared at the points for which $\varphi = 90°$.

The lower half of figure 8 shows the different positions of minimum sparking. A A′ is the primary conductor, and the lines $m\ n$ represent the projections of the secondary circuit on the horizontal plane. The arrows perpendicular to these give the direction of the resultant lines of force. As this did not anywhere vanish in passing from the sphere A to the sphere A′, it could not change its sign.

The diagram brings out the two following points:—

(1) The distribution of the resultant E. M. F. in the vicinity of the rectilinear vibration is very similar to that of the electrostatic E. M. F. due to the action of its two extremities. It should be specially noted that near the centre of the primary the direction is that of the electrostatic E. M. F., showing that it is more powerful than the electro-dynamic, as required by theory.

(2) The lines of force deviate more rapidly from the line A A′ than the electrostatic lines, though this is not so evident on the reduced scale of the diagram as in the author's original drawings on a much larger scale.

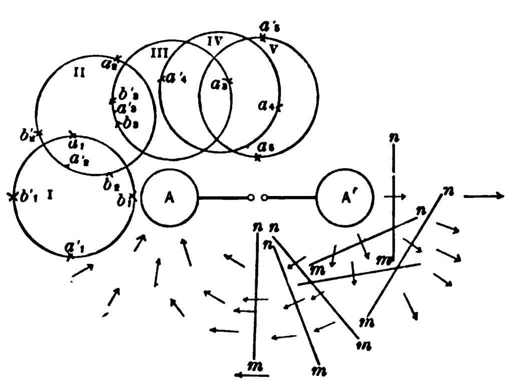

Fig. 8.

It is due to the components of the electrostatic E. M. F. parallel to A A′ being weakened by the E. M. F. of induction, while the perpendicular components remain unaffected.

Experiments with the secondary circuit in a horizontal plane.—The results obtained when the plane of the secondary was horizontal can best be explained by reference to the upper half of the diagram in figure 8.

In the position I, with the centre of the circle in the line A A′ produced, the sparks disappeared when the air space occupied either of the positions b_1 or b'_1, while two equal maxima of the sparking distance were obtained at a_1 and a'_1, the length of the spark in these positions being 2.5 millimeters. Both these results are in accordance with theory.

In the position II, the circle is cut by the electro-magnetic lines of force, and, therefore, a does not vanish. It will, however, be small, and we should expect that the expression $a + \beta \sin \theta$ would have two unequal maxima $\beta + a$ and $\beta - a$, both for $\theta = 90°$, and having the line joining them perpendicular to the resultant E. M. F., and between these two maxima we should expect two points of no sparking near to the smaller maximum. This was confirmed by the observations.

The maximum sparking distances were 3.5 millimeters at a_2 and two millimeters at a'_2. Now with the air space at a_2, the sphere A being positive, the resultant E. M. F. in the opposite portion of the circle will repel positive electricity from A, and therefore tend to make it flow round the circle clockwise. Between the two spheres the electrostatic E. M. F. acts from A towards A′, and the opposite E. M. F. of induction in the neighborhood of the primary acts from A′ to A, parallel to the former, and acting more strongly on the nearer than on the further portion of the secondary, tends to cause a current in the same direction as that due to the former, namely, in a clockwise direction. Thus the resultant E. M. F. is the sum of the two as required by theory, and in the same way it is easily seen that when the air space is at a'_2, the resultant E. M. F. is equal to their difference.

As the position III is gradually approached, the maximum disappears, and the single maximum sparking distance a_3 was found to be four millimeters in length, having opposite to it a point of disappearance a'_3. In this case clearly $a = \beta$, and the sparking distance is given by the expression $a\ (1 + \sin \theta)$. The line $a_3\ a'_3$ is again perpendicular to the resultant E. M. F.

As the circle approaches further towards the centre of A A′ a will become greater than β, and the expression $a + \beta \sin \theta$ will not vanish for any value of θ, but will have a maximum $a + \beta$ and a minimum of $a - \beta$, and in the experiments it was found that the sparks never entirely disappeared, but varied between a maximum and a minimum, as indicated by theory.

In the position IV, a maximum sparking distance of 5.5 millimeters was observed at a_4 and a minimum of 1.5 millimeters at a'_4.

In the position V there was a maximum sparking distance of six millimeters at a_5 and a minimum of 2.5 millimeters at a'_5. In these experiments the air space should be screened off from the primary in the latter positions as well as in the earlier ones, in which it is unavoidable, as otherwise the results would not be comparable.

In passing from the position III to the position V the line $a\ a'$ rapidly turned from its position of parallelism to the primary circuit into a position perpendicular to it. In the latter positions the sparking was essentially due to the inductive action, and therefore the author was justified, in the experiments described in my previous papers, in assuming the effect in these positions to be due to induction.

Even in these positions, however, the sparking is not totally independent of electrostatic action, except when the air space is half way between the maximum and minimum positions, and therefore, $\beta \sin \theta = 0$.

Other positions of the secondary circuit.—Dr. Hertz made numerous observations with the secondary circuit in other positions, but in no case were any phenomena observed which were not completely in accordance with theory. As an example of these consider the following experiment :—

The secondary was first placed in the horizontal plane in the position V (figure 8*), and the air space was in the position a_5 relatively to the primary. The circle was then turned about a horizontal axis through its centre and parallel to the primary, so as to raise the air space above the horizontal plane. During this rotation θ remained equal to 90°, and the value of β remained nearly constant, but a varied approximately in the same ratio as $\cos \Psi$, Ψ being the angle between the plane of the circle and the horizontal, for a is proportional to the number of magnetic lines of force passing through the circle. Let a_0 be the value of a in the initial position, then in the other positions its value would be $a_0 \cos \Psi$, and therefore the sparking distance should be given by the expression $a_0 \cos \Psi$, $+ \beta$, in which a_0 was known to be greater than β. This was confirmed by observation, for it was found that as the

*See *The Electrician*, October 5th, 1888, page 697.

air space increased its height above the horizontal plane the sparking distance diminished from 6 millimeters down to 2 millimeters, its value when the air space was at its greatest distance above the horizontal plane. During the rotation through the next quadrant the sparking distance diminished almost to zero, and then increased to the smaller maximum of 2.5 millimeters, which it attained when the circle had turned through 180°, and was therefore again horizontal. Similar results were obtained in the opposite order, as the circle was rotated from 180° to 360°. When the circle was kept with the air space at its maximum height above the horizontal plane, and then raised or lowered bodily without rotation, the sparking distance was found to diminish in the former case and to increase in the latter, results completely in accordance with theory.

Forces at greater distances.—Experiments with the secondary at greater distances from the primary are of great importance, as the distribution of E. M. F. in the field of an open circuit is very different according to different theories of electro-dynamic action, and the results may, therefore, serve to eliminate some of them as untenable. In making these experiments, however, an unexpected difficulty was encountered, as it was found that at distances of from 1 to 1.5 meters from the primary the maximum and minimum, except in certain positions, became indistinctly defined; but when the distance was increased to upwards of two meters, though the sparks were then very small, the maximum and minimum were found to be very sharply marked when the sparks were observed in the dark. The positions of maximum and minimum were found to occur with the circle in planes at right angles to each other. At considerable distances the sparking diminished very slowly as the distance was increased. Dr. Hertz was not able to determine an upper limit to the distance at which sensible effects took place, but in a room 14 meters by 12, sparks were distinctly observed when the primary was placed in one corner of the room, wherever the secondary was placed. When, however, the primary was slightly displaced, no effects could be observed, even when the secondary was brought considerably nearer. The interposition of solid screens between the two circuits greatly diminished the effect.

Dr. Hertz mapped out the distribution of force throughout the room by means of chalk lines on the floor, putting stars at the points where the direction of the E. M. F. became indeterminate. A portion of the diagram obtained in this manner is shown on a reduced scale in figure 9, with respect to which the following points are noteworthy:—

1. At distances beyond three meters the E. M. F. is everywhere parallel to the primary oscillation. Within this region, therefore, the electrostatic E. M. F. is negligible in comparison with the E. M. F. of induction. Now, all the theories of the mutual action of current elements agree in giving an E. M. F. of induction inversely proportional to the distance, while the electrostatic E. M. F. being due to the differential action of the two extremities of the primary, is approximately inversely proportional to the cube of the distance. Some of these theories, however, are not in accordance with the experimental result that the effect diminishes much more rapidly in the direction of the primary oscillation than in a direction at right angles to it, induced sparks being observed at a distance exceeding 12 meters in the latter direction, while they disappeared at a distance of about four meters in the former direction.

2. That, as already proved, for distances less than one meter the distribution of E. M. F. is practically that of the electrostatic E. M. F.

3. There are two straight lines, at all points of which the direction of the E. M. F. is determinate, namely, the line in which the primary oscillation takes place, and the perpendicular to the primary through its middle point. Along the latter the E. M. F. does not vanish at any point, the sparking diminishes gradually as the distance is increased. This, again, is inconsistent with some of the theories of mutual action of current elements, according to which it should vanish at a certain definite distance. A very important result of the investigation is the demonstration of the existence of regions within which the direction of the E. M. F. becomes indeterminate. These regions form two rings encircling the primary circuit. Since the E. M. F. within them acts very nearly equally in every direction, it must assume different directions in succession, for of course, it cannot act in different directions simultaneously.

The observations, therefore, lead to the conclusion that within these regions the magnitude of the E. M. F. remains very nearly constant, while its direction varies through all the points of the compass at each oscillation. Dr. Hertz states that he has been unable to explain this result, as also the existence of overtones, by means of the simplified theory in which the higher terms of the expansion of F are neglected, and he considers that no theory of simple action at a distance is capable of explaining it. If, however, the electrostatic E. M. F. and the E. M. F. of induction are propagated through space with unequal velocities, it admits of very simple explanation. For within these annular regions the two E. M. F.'s are at right angles and of the same order of magnitude; they will, therefore, in consequence of the distance traversed, differ in phase, and the direction of the resultant will turn through all the points of the compass at each oscillation.

This phenomenon appears to him to be the first indication which has been observed of a finite rate of propagation through space of electrical actions, for if there is a difference in the rate of propagation of the electrostatic and electro-dynamic E. M. F., one at least of them must be finite.

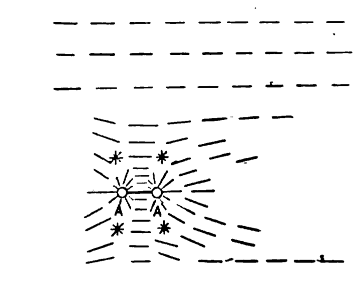

Fig. 9.

At the end of the paper in which the preceding experiments are described Dr. Hertz describes some observations which he has made on the conditions at the primary sparking point which affect the production of sparks in the secondary circuit. He finds that illuminating the primary spark diminishes its power of exciting rapid oscillations, the sparks in the secondary being observed to cease when a piece of magnesium wire was burnt, or an arc lamp lighted, near the primary sparking point. The observed effect on the primary sparks is that they are no longer accompanied by a sharp crackling sound as before. The effect of a second discharge is especially noteworthy, and it was found that the secondary sparks could be made to disappear by bringing an insulated conductor close to the opposed surfaces of the spheres forming the terminals at the primary air space, even when no visible sparking took place between the latter and the insulated conductor. The secondary sparking could also be stopped by placing a fine point close to the primary air space, or by touching one of the opposed surfaces of the terminals with a piece of sealing-wax, glass, or mica. Dr. Hertz states that further experiments have led him to conclude that, even in these cases, the effect is due to light too feeble to be perceived by the eye, arising from a side discharge. He points out that these effects afford another example of the effects of light on electric discharges, which have been observed by E. Wiedemann, H. Ebert, and W. Hallwachs.

Dr. Hertz's next paper in order of publication in Wiedemann's *Annalen*, "On Some Induction Phenomena arising from Electrical Actions in Dielectrics" (Wiedemann's *Annalen*, vol. xxxiv., p. 273), contains an account of some researches undertaken with a view of obtaining direct experimental confirmation of the assumption involved in the most suggestive theory of electrical actions, viz., that of Faraday and Maxwell, that the well-known electrostatic phenomena observed in dielectrics are accompanied by corresponding electro-dynamic actions. The method of observation consisted in placing a secondary conductor adjusted to unison, as regards electrical oscillations, with the primary, as near as possible to the former, and in such a relative position that the sparks in the primary produced no sparking in the secondary. As the equilibrium could be disturbed and sparking induced in the secondary by the approach of conductors, it formed a kind of induction balance; but the point of special interest in connection with it was that a similar effect was produced when the conductors were replaced by insulators, provided the latter were of comparatively large size. The observed rapidity of the oscillations induced in the dielectrics showed that the quantities of electricity in motion under the influence of dielectric polarization were of the same order of magnitude as in the case of metallic conductors.

The apparatus employed is shown diagrammatically in figure 10, and was supported on a light wooden framework,

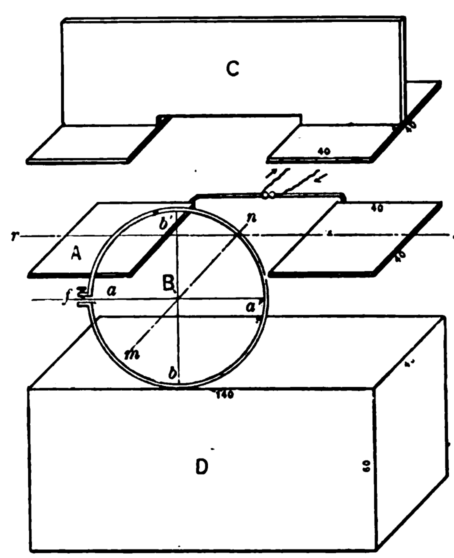

Fig. 10.

not shown in the illustration. The primary conductor consisted of two brass plates, A A', with sides 40 centimeters in length, joined by a copper wire 70 centimeters long and half a centimeter in diameter, containing an air space of three-quarters of a centimeter, with terminals formed of polished brass spheres. When placed in connection with a powerful induction coil, oscillations are set up, the period of which, determined by the dimensions of the primary, can be determined to within a hundredth-millionth of a second. The secondary conductor consisted of a circle, 35 centimeters in radius, of copper wire two millimeters in diameter, containing an air space, the length of which could be varied by means of a screw from a few hundredths of a millimeter, up to several millimeters. The dimensions stated were such as to bring the two conductors into unison, and secondary sparks up to six or seven millimeters in length could be obtained.

The circle was movable about an axis through its centre perpendicular to its plane, to enable the position of the air space to be varied. The axis was fixed in the position *m n* in the plane of A and A', and half-way between them. The centre of the circle was at a distance of 12 centimeters from the nearest points of A and A'.

When *f* was in either of the positions *a* or *a'* lying in the plane of A A' no sparking occurred in the secondary, while maximum sparking took place at *b* and *b'* 90° from the former positions. The E. M. F. giving rise to the secondary sparks is, as in previous experiments, partly electrostatic and partly electro-magnetic, and the former being the greater will determine the sign of the resultant E. M. F. The oscillations must, for the reason previously explained, be considered as produced in the part of the secondary most remote from the air space. Assuming the E. M. F. and the amplitude of the resulting oscillation to be positive when *f* is in position *b'*, they will both be negative when *f* is at *b*.

When the circle was slightly lowered in its own plane the sparking distance was increased at *b'* and diminished at *b*, and the null points lay at a certain distance below *a* and *a'*. The electrostatic E. M. F. is scarcely affected by such a displacement, but the integral of the E. M. F. of induction taken round the circle is no longer zero, and therefore gives rise to an oscillation which will be of positive sign whatever be the position of *f*, for the direction of the resultant E. M. F. of induction is opposite to that of the electrostatic E. M. F. in the upper part of the circle, and coincides with it in the lower half where the electrostatic E. M. F. has been assumed to be positive. Since the new oscillation so produced is in the same phase as the previously existing one their amplitudes must be added to give the resultant amplitude, which explains the phenomena.

Effects of the approach of conductors.—In making these observations it was found necessary to remove all conductors to a considerable distance from the apparatus, in order to obtain a complete disappearance of sparking at the points *a* and *a'*. Even the neighborhood of the observer was sufficient to set up sparking when the air space *f* was in either of these positions, and the sparks had therefore to be observed from a distance. The conductors used for the experiments was of the form shown at C (figure 10), and consisted of thin metal foil. The objects kept in view in selecting the material and dimensions were to obtain a conductor which would give a moderately large effect, and having an oscillation period less than that of the primary.

When the conductor C was brought near to A A', it was found that the sparking distance decreased at *b* and increased at *b'*, and the null points were displaced upwards—that is, in the direction of C.

From the results of experiments already described it is evident that the effect of displacing A A' upwards would be the same, qualitatively, as that of a current in the same direction as that in A A' directly above it. The effect produced by the approach of C was the reverse of this, and could be explained by an inductive action, supposing there were a current in C in the opposite direction to that in A A', which is exactly what must occur; for the electrostatic E. M. F. would give rise to such a current, and since the oscillations in C are more rapid than those of this E. M. F., the current must be in the same phase as the inducing E. M. F. The truth of this explanation was confirmed by the following experiments. The horizontal plates of the conductor C being left in the same position as before, the vertical plate was removed, and successively replaced by wires of increasing length and fineness, in order to lengthen the oscillation period of C. The effect of this was to displace the null points more and more in an upward direction, while at the same time they became less sharply defined, a minimum sparking taking the place of the previous absolute disappearance. The sparking distance at the highest point had previously been much less than at the lowest point, but after the disappearance of the null points it began to increase. At a certain stage the sparking distance at the two positions became equal, and then no definite minimum points could be found, but sparking took place freely at all positions of *f*. Beyond this stage the sparking distance at the lowest point diminished, and very

soon two minimum points made their appearance close to it, not clearly defined at first, but gradually becoming more distinct, and at the same time approaching the points a a', with which they ultimately coincided, when the minimum points again became absolute null points. As the oscillation period of C approaches that of A A′, the intensity of the current in the former increases, but a difference of phase arises between it and the exciting E. M. F. When the two are in unison the current in C attains its maximum, and, as in other cases of resonance, the difference of phase gives rise to a slightly damped oscillation, having a period of about a quarter that of the original one, which makes any interference between the oscillations excited in the circle B by A A′ and C respectively impossible. These conditions clearly correspond to the stage at which the sparking distances at b and b' were equal. When the oscillation period of C becomes decidedly greater than that of A A′, the amplitude of the oscillation in the former will again diminish, so that the difference in phase between it and the exciting E. M. F. will approach half of the original period. The current in C will therefore always be in the same direction as that in A A′, so that interference between the two oscillations excited in B will again become possible, and the effect of C will then be opposite to its original effect. When the conductor C was made to approach A A′ the sparks in B became much smaller, which is explained by the fact that its effect will be to increase the oscillation period of A A′, and therefore to throw it out of unison with B.

(*To be continued.*)

THE WESTERN ELECTRIC INCANDESCENT LIGHTING SYSTEM.

The Western Electric Company, of Chicago, New York, London and Antwerp, whose venture into the field of electric lighting with its arc system a few years ago has proved so successful, have introduced recently an incandescent lighting system of their own design and manufacture, which possesses several new and interesting features.

The type of field magnet frame used in their now familiar arc lighting dynamo is not used in the construction of their incandescent lighting machine, a simpler form, and one better adapted to this class of work, having been adopted.

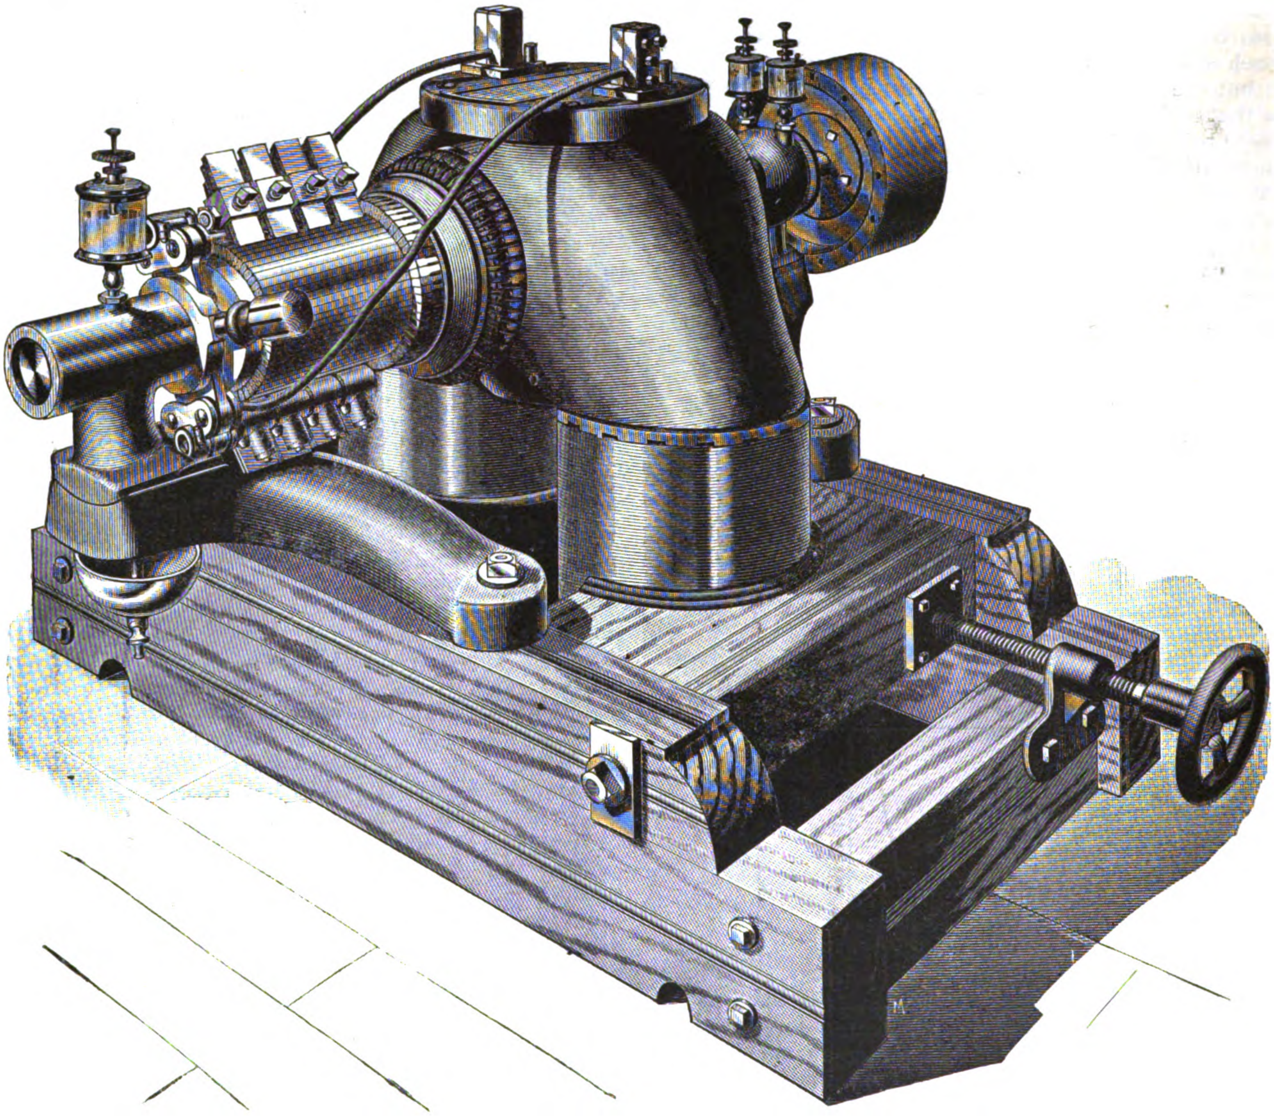

Fig. 1.—Western Electric Incandescent Dynamo.

Figure 1 illustrates a complete dynamo, while figure 2 shows a field magnet, pole-pieces and frame only. The whole iron base is cast in one piece. The cores of the field magnets are made of soft iron and the pole-pieces are cast upon the upper ends of the cores. The lower ends of the cores are bolted to the cast-iron base. There are, therefore, only two magnetic joints in the whole field system. The field magnet coils are connected in shunt with the armature. The automatic regulation thus secured is found to be practically perfect. Any number of lamps may be cut in or out without visibly affecting the candle-power or brilliancy of the remaining lamps throughout a circuit. The armature is of the drum type, and is wound in a simple and peculiar way, avoiding all joints in the wires but two. The electrical and commercial efficiency of the dynamo is said

to be very high, while in its mechanical construction and workmanship it is quite up to or above the average practice of the day. The machine is provided with a self-adjusting bearing on the pulley side.

The peculiar form of the cast-iron base and the manner in which it is inserted and secured in the wooden carriage, result in bringing the armature shaft at a convenient height from the floor—but not so high as is usually the

FIG. 2.—Western Electric Incandescent Dynamo. Frame, Field Magnets and Pole-Pieces.

case in dynamos having this type of field magnet—while at the same time it permits the use of the sliding carriage for adjusting belt tension without raising the dynamo so high as to render it unstable. On the top of the pole-

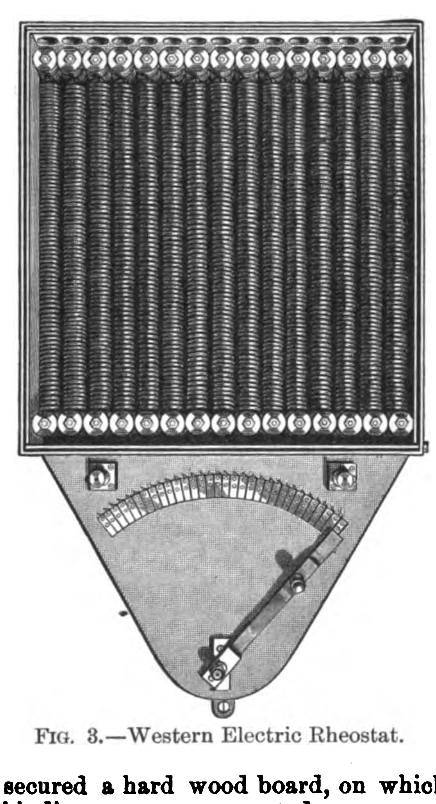

FIG. 3.—Western Electric Rheostat.

pieces is secured a hard wood board, on which the field and main binding posts are mounted.

The rheostat, figure 3, is non-combustible. It consists of a cast-iron frame provided with porcelain insulators, to which the german-silver wire coils are attached. The front of the rheostat box is covered with glass, preventing dirt and dust from getting into the box and at the same time allowing ready inspection.

Figures 4 and 5 represent the voltmeter and ammeter. These instruments are dead beat, and may be left in the circuit permanently without overheating.

The lightning arrester is very simple in its operation and requires no automatic cut-outs or safety strips for the prevention of short circuits. The jaws of

FIG. 4.—Western Electric Voltmeter.

this lightning arrester are made of carbon plates. In case the dynamo current should follow a discharge of atmospheric electricity an arc may be set up, but this will burn away the carbon points and thus free the dynamo of the short circuit. Such a carbon lightning arrester can, of course, only be used for low tension dynamos.

A multiple safety cut-out board is used where wires are run to central distributing points, which are located in closets. All the safety devices are provided with glass covers to keep out dust and at the same time allow of easy inspection.

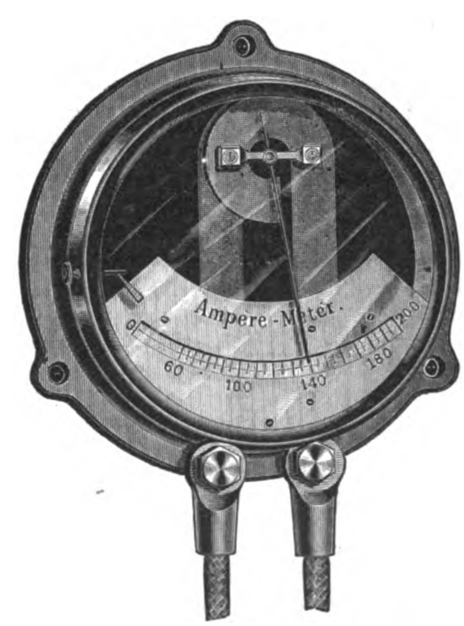

FIG. 5.—Western Electric Ammeter.

Every feature of an isolated incandescent lighting outfit has been fully provided for and the whole system is carefully worked out to the smallest details. Particular attention has been given to securing simplicity of design and excellence of workmanship.

The ample resources of the Western Electric Co. and its extended experience in general electrical manufacturing, together with its acquired practice in arc lighting machinery supplemented by the services of electricians skilled in incandescent lighting, who have recently been added to its staff, have been brought to bear for the purpose of producing apparatus of the best design and construction and of high efficiency.

ABSTRACTS AND EXTRACTS.

THE INSTITUTION OF ELECTRICAL ENGINEERS.[1]

Sir William Thomson's Inaugural Address.

For more than one reason the meeting of this Institution, held on the 10th inst. [January, 1889], was of special interest. It was the first meeting which the Society held after officially assuming its new name; it was a meeting at which the new president, Sir William Thomson, delivered his inaugural address, and the attendance was larger than we have ever known it to be before. * * * * After some formal business, including the readjustment of prizes, which was necessitated by the generous offer of Professor Silvanus Thompson to forego the first prize awarded to him for his paper on influence machines in favor of some younger member of the Institution, the retiring president, Mr. Graves, vacated the chair, which was then occupied by Sir William Thomson, who delivered his inaugural address. The title of the address was "Ether, Electricity, and Ponderable Matter,"and the subject being one which has occupied the most profound thinkers of the old and new world for over a generation, and especially Sir William Thomson for the last forty years, it will be readily understood that his address was of absorbing interest, and we give a brief abstract of it.

The president began by reminding his hearers that when he occupied the presidential chair fourteen years ago the Society was in the third year of its existence, and contained only 570 members, which number had now increased to 1550. He pointed out that the Society owed its origin mainly to Sir William Siemens, and alluded with regret to the numbers who had passed away since its foundation. Among these were the two first presidents, Sir William Siemens and Mr. Frank Scudamore, and three later presidents—Mr. Walker, Colonel Champney, and Sir Charles Bright, his colleague in the laying of the first Atlantic cable in 1857. The Society, originally founded as the "Society of Telegraph Engineers," had grown in scope as well as in numbers, as shown by its successive changes of title—first to "Society of Telegraph Engineers and Electricians," and finally to "Institution of Electrical Engineers." At its first foundation, the only electrical industries were telegraphy and electro-metallurgy. To these there had now been added telephony, the electrical transmission of power, electric haulage, applications to naval and military operations, and last, but not least, electric lighting. Referring to the connection between electrical and civil engineering, Sir William pointed out that in his presidential address of fourteen years ago he had called attention to the great mistake made by architects in not being at the same time engineers. Electrical engineers, however, were not open to a similar reproach, as they were fully alive to the essential necessity of being engineers before they become electricians. The idea was a great deal too prevalent that a mere taste for electricity was an indication of the fitness of a youth for the profession of an electrical engineer, and it was therefore most necessary to insist upon the fact that electrical engineering was not confined to electricity and ether, but had to deal with ponderable matter as well; and the aspirant to the profession, after having received a good general education, must obtain a competent knowledge of mathematics and dynamics, and should be thoroughly trained in the principles of mechanical and civil engineering. The requisite knowledge of electricity for a commencement could then be acquired in a short time, but he must be prepared to be ever learning and extending his knowledge of electrical phenomena throughout the whole of his professional career.

Turning, after these introductory remarks, to the immediate subject of his address, the president remarked that the demand for some kind of mechanical explanation of electrical phenomena was not new, but was now growing in intensity. With regard to the gradual growth of the demand, he referred to some of the past presidential addresses, and the first who called attention to the subject in this manner was Mr. Preece, who, in his presidential address in 1883, dwelt on the relations which Maxwell had shown to exist between electricity and light; while on a subsequent occasion Mr. Willoughby Smith had briefly referred to some very interesting experiments of his own upon the screening effects of sheets of different metals upon electromagnetic induction, or, perhaps, he ought to say, electrical induction, as it was fast becoming impossible to specially differentiate induction. The mathematical theory of these phenomena had been very ably worked out by Horace Lamb and W. D. Niven. In a still later address, Professor Hughes had described his wonderfully interesting experiments on induction, and though the forms in which some of his statements were cast were criticised from the mathematical point of view, even these statements, by giving rise to such criticism, had afforded a powerful stimulus to the advance of our knowledge of the subject.

One of the first problems in electrical induction which was worked out in detail, arose in submarine telegraphy. The researches of Henry and Faraday had given us a general knowledge of the phenomena of electro-magnetic induction between two wires. The electro-static induction due to the Leyden jar discharge was also explained by Faraday, who laid the foundation for all the subsequent advances in the knowledge of this phenomenon, by showing that the conduction of a charge through the wire necessarily raised its potential by a definite amount above that of the earth. Cromwell Varley had developed Faraday's work in several important points, while Stokes and the speaker had mathematically worked out the theory of induction in cables. The mathematical investigations showed that in the case of cables of more than two hundred or three hundred miles in length, the speed of working was so limited by electro-static induction, that the electro-magnetic induction could not possibly produce any appreciable effect, and it was therefore omitted entirely from the theory. This would not be the case if the cable were only fifty miles in length. The speaker had partly worked out this question in order to test the range of applicability of the theory which only took account of the electro-static induction; and the question was further brought into notice by Werner and Charles Siemens, when laying their Mediterranean cables. Then the electro-magnetic induction was considered the most important; but the speaker found that its effect would be absolutely imperceptible, and in consequence of the result of his investigation, Messrs. Siemens abandoned their proposed plan of forming the conductor of two thin wires close together, as this arrangement would have increased the electro-static induction, which was the important factor. The question had now again come to the front, and Mr. Oliver Heaviside had worked it out very completely. Heaviside had pointed out that the electro-magnetic induction instead of being harmful, was actually beneficial, having the same effect as that of mass in such a case as a boat running upon wheels in a viscous fluid. If impulsive forces were applied to two such boats of different masses, the one of greater mass would require a greater

1. From *Industries*.

force to set it in motion; but when once in motion it would go further. In the same way, when the electro-magnetic induction was considerable, greater electric force, so to speak, was required to set the current in motion; but once started, it would travel further. Heaviside had brought into prominence the well-known fact that the effect of a leak in a cable is in itself beneficial, and if it could be kept constant, and prevented from introducing earth currents, it would increase the distinctness of the signals. The distinctness of the signals did not depend so much on the amplitude of the current wave, or on the increase of potential at the remote end, as on the retardation of the phase, though the diminution of amplitude with increasing distance had to be considered as well. If the variations of each of these were constant throughout the length of the cable, then perfect distinctness of signals would result. In the case of transmission of sound, the retardation of phase, and the diminution of intensity with the distance, being the same for all notes, there was no loss of clearness with increasing distance. Heaviside had shown that the effect of electro-magnetic induction was to diminish the difference in phase, tending to make it the same throughout, and Sir William pointed out that the retardation of electrical waves was exactly similar to that of light waves. These developments in the theory were of great practical value, as in the case of telephonic currents the frequency varied from 256 alternations a second up to as much as four times that amount, and with these high frequences the electro-magnetic induction became perceptible, and there was no doubt that the clearness with which sound was transmitted by the telephone was due in great part to the fact that the high frequency of alternation greatly diminished the differences in the alternation of different notes. Sir William then went on to consider the relative advantages of iron and copper as telephonic conductors, and stated that information which he had received from Mr. Bennett, the engineer of the National Telephone Company of Scotland, established beyond a doubt that the articulation was much less distinct when iron wires were used as conductors, than with copper wires of equal resistance. In all probability the investigations by Mr. Oliver Heaviside, and by Lord Rayleigh, into the susceptibility of iron to small differences in magnetic force, would lead to a complete explanation of this fact. The speaker had worked out some numerical results in the problem of the transmission of alternating currents through telephonic or electric light conductors. The calculations had to be made by the aid of Bessel's Functions, a modified form of Laplace's Functions, or Spherical Harmonics, suitable for treating the problem of the variation of the potential at the ends of an infinitely long cylindrical copper wire, or for its treatment in the case of an infinitely long copper wire surrounded by a concentric cylindrical copper conductor, or of two infinitely long parallel copper wires. The latter problem was as easy as that of the wire and concentric tubular conductor, provided the distance between the two wires was great enough to prevent the current in one from influencing the distribution of current throughout the interior of the other, as in this case the disturbance was independent of the surroundings. This condition would be fulfilled in the cases occurring in practical telegraphy. Assuming a frequency of eighty alternations a second, which was about the frequency adopted in the current supplied from the Grosvenor Gallery installation, he found that in the case of a copper wire 2 centimeters in diameter the ohmic resistance was 8 per cent. more for the alternating current than for a direct current, 63 per cent greater for a wire 4 centimeters in diameter, four times as great for a wire 10 centimeters in diameter, and seventeen times as great for a wire 100 centimeters in diameter. When the diameter exceeded 10 centimeters, the ohmic resistance, that is, the reciprocal of the ohmic resistance, increased sensibly in direct proportion to the circumference, and not in proportion to the square of the diameter. For smaller diameters the relation was much more complicated, and could only be expressed in terms of Bessel's Functions. The numbers applying to a wire of given diameter, with a given rate of alternation, would be the same for a wire of half the diameter, provided the frequency were four times as great. Thus for a frequency of 320 alternations a second, a copper telephone wire 1 centimeter in diameter would have an ohmic resistance 8 per cent. greater than for a steady current; for a diameter of two centimeters, the ohmic resistance would be 63 per cent. greater, and so on. The conductivity of the wire was therefore of much less importance in the case of telephone wires than in the case of electric light wires; for if the frequency were sufficient to greatly increase the ohmic resistance, the current would be proportional to the reciprocal of the square root of the resistance, instead of to the reciprocal of the resistance, as in the case of a steady current. The diameter of a telephone wire should therefore be chosen so as not to increase the ohmic resistance to such an extent as to sensibly disturb the uniformity of distribution. Sir William pointed out that the equations of motion of a viscous fluid which were first given by Professor Stokes were identical with those which determined the distribution of current in a conductor, and therefore there was an exact analogy between the two cases; and as Heaviside had pointed out, this analogy was most helpful, because it was comparatively easy to form a mental image of the phenomena in the fluid, but impossible to do so in the electrical problem. Thus a cylindrical copper wire, carrying an alternating current, might be compared to a cylindrical tube of infinite length (or the tube might be of great length in comparison with its diameter, and fitted with frictionless pistons at its extremities, and the portion of fluid considered should be at a distance of many diameters from the ends), containing a viscous fluid, and moved to and fro with a simple harmonic motion. If the fluid were non-viscous, no motion would be produced in it by the motion of the tube; but if viscous, the alternate motion would penetrate inwards from the surface, just as in the case of the current in the wire. Another analogy might be found by considering a cylindrical conducting solid, embedded in some substance such as rock, subject to variation in temperature. The penetration of maxima, minima, and zero temperatures into the cylinder would then follow the same law as the penetration of motion into the fluid, or of electric current into the wire.

Another case in which the viscous fluid analogy held good, though the thermal one broke down, was that of the penetration of an induced current into the copper core of a solenoid. This might be compared with the penetration of motion into a viscous fluid contained in a tube rotated with varying velocity; and the speaker pointed out that if the penetration were very small, it would follow the same law as in the case of the tube being moved longitudinally to and fro. In the case of iron cores, the complications introduced by the variation in the magnetic susceptibility with the strength of the magnetic induction were so great that the problem was at present completely beyond the power of mathematical analysis.

The case of two parallel wires carrying alternate currents could be represented by alternate rotations in opposite directions, density would correspond to resistance, and a change of density would correspond to a change of one metal to another; while an insulator would be represented by a viscous fluid devoid of inertia. The electro-static effect could be represented by introducing a change of phase, and giving a certain amount of stiffness to the fluid, and the analogy could be extended to the case of a submarine cable by the introduction of an arbitrary normal force at the surface; but though a perfect mathematical analogy, and therefore of great help in the mathematical treatment of the subject, the analogy could not be considered in any sense a physical one, owing to the arbitrary character of the force introduced. Sir William also pointed

out that the analogue of an electric current was not a molecular rotation of the fluid, but in Maxwell's terminology the rotation of the vector representing the velocity of the fluid at any point, that is to say, the vector portion of the quantity obtained by operating on this vector by Laplace's operator. Clifford called this quantity the "curl" of the vector, and Sir William regretted that Heaviside had adopted the term, as he preferred the term "rotation." The analogue of a steady current was obtained by pressing in the piston at one end, when the motion, though disturbed in the neighborhood of the piston by the rigidity of the latter, would be quite regular at a distance of say 20 diameters. The velocity would be a maximum at the centre of the tube, and zero at the surface. Taking a longitudinal section through the axis of the tube, the particles of fluid originally lying along a transversal perpendicular to the sides of the section would lie upon a curve of parabolic form, and there were then two things to be considered to determine the motion, viz.: the rate of shearing, and the rate of change in the rate of shearing per unit of distance from the surface of the tube. The latter quantity, which was the analogue of the velocity of the current, was measured by the tangent of the angle of inclination to the transversal of the tangent to the parabolic curve at the point considered.

Sir William then went on to observe that he believed that an electric current actually caused a rotation in the ether, and considered the case of a helix surrounding a copper core. Induced currents were set up in the copper, and the only action conceivable in the space included between the helix and the core was a rotation. This might be either a continuous rotation or a rotation through an angle proportional to the strength of the current. In iron, however, something quite different must take place. If the fluid moved round continuously, there would be no shearing; if, on the other hand, there were only a drag upon the ether through a certain angle, then there must be a force resisting steady rotation—that is to say, there would have to be an arrangement of matter of such a character that a constant torque would produce a constant, instead of an accelerated, rotation. It would appear that such an effect could only be produced by an inherent rotation of the molecules. Sir William proceeded to show that it was quite possible to form a conception of a medium of the kind required. For imagine a number of squares, with their sides parallel, fixed together with elastic bands, and suppose each square to contain a gyrostat in the form of a rotating molecule. Then one of these squares could only be turned out of its plane by the application of a minimum torque equal to the time integral of the moment of inertia of the gyrostat. Such a medium without the gyrostats would have the properties of a perfect liquid; but with the gyrostats in place, turning could only take place by stretching the elastic bands, which would require a constant torque. While pointing out that this was a very gross illustration, he thought it of value, as the mere fact that they could conceive of such a mechanism might be considered as indicating that a mechanism having these properties, though not at all resembling our conception, might actually exist in nature. On this hypothesis the observed phenomena would indicate that the ether must be less rigid in iron than in other metals, and have the same value for all non-magnetic metals. In iron, therefore, the velocity of the rotating molecules would have to be less than in other substances. In concluding, Sir William pointed out that even the very imperfect attempts at a mechanical explanation of electrical phenomena which he had indicated would only apply to very small parts of the subject, and the tremendous difficulties in the way of a complete mechanical explanation prevented him from hoping to see the question solved in his own lifetime, though he felt confident that a solution would be found, and that what appeared so insuperable a mystery to us would be no mystery at all to future generations. At the conclusion of his address Sir William exhibited some very interesting experiments with a large gyrostat, in illustration of the properties which he had assumed in the construction of the ether.

THE HAMBURG ELECTRIC LIGHTING STATION.[1]

This station, although built for the immediate supplying of 12,000 16 c. p. lamps, has an extension ready to meet an anticipated call for double that number. The two-wire system is employed. The entire 12,000 lamps, can, if necessary, be supplied with current at the same time. The plant includes a dynamo to supply 67,000 volt amperes; and five dynamos, each supplying 134,000 volt amperes. The small dynamo, and one of the larger ones are each connected with a separate steam engine, while the remaining four are driven in pairs by two engines. The engines are of the vertical, compound type, with condensers. The dynamos are Schuckert's flat ring machines, which at 300 revolutions give the above-named output of 67,000 and 134,000 volt amperes respectively.

The whole consumption is furnished through 18 principal circuits, of which two run to the theatre. The fall of potential for the full consumption of 12,000 lamps, is 15 volts in the principal wires, and 1.5 volts in the branch circuits. The combined length of wire is 30 kilometers (18.6 miles), and the greatest distance from station 900 meters (0.56 miles). The conductors, which are cables with double lead covering, are bedded in U-iron ducts decked with iron plates. The principal conductors terminate in iron boxes divided into compartments in which the cables lie, surrounded by an insulating substance. Each principal cable contains two testing wires, for the controlling, regulating and signaling apparatus. Any increase beyond the present consumption is to be met by the addition of other conductors, for which purpose the U-iron troughs are made of sufficiently large dimensions. For the extension of conductors beyond their present territory, it is proposed to employ the three-wire system, laying additional conductors for use in connection with the two-wire conductors now in service. Points lying very far from the central station are to be supplied with indirect current by means of continuous current transformers or accumulators.

DISCUSSION ON LIGHTNING CONDUCTORS AT THE BRITISH ASSOCIATION.[1]

(Concluded from page 179.)

Mr. Walker, Sen., having made some remarks on the striking of an obelisk which he had witnessed,

Mr. Trueman Wood said that the dark flash before referred to could not be due to over-exposure, because the white one, which was presumably, according to that theory, less exposed, overrode the black. He considered that the black flash was evidently produced by tralation, or reflection from the back surface of the glass plate.

The President then called upon Lord Rayleigh, Professor Lodge, and Mr. Preece to reply.

Lord Rayleigh said that Professor Stokes had once made a suggestion that, he believed, had never been published, to the effect that it was possible for the black flashes, which he (the speaker) thought, with Mr. Trueman Wood, were evidently not caused by over-exposure, to be accounted for in the following way. Professor Stokes thought that, under the influence of a lightning flash, the atmospheric gases—oxygen and nitrogen—were combined so as to produce considerable quantities of the oxides of nitrogen; that those oxides of nitrogen, formed along the line of the flash, were opaque to the invisible rays at the upper limit of the spectrum to which most of the photographic action was due; and that this, when another flash occurred, illuminating the background of the cloud, would darken the place where the first flash had been. Hence the mark of the flash would appear as a black line, on account of its opacity to the general first light of the background.

Professor Oliver Lodge said that so many things had been remarked, and so much might be said on points which had not

1. From the *Electrotechnische Zeitschrift*, March, 1889.

1. From *Industries*, November 23, 1888.

been commented upon, that one must exercise selection in what one mentioned. Mr. Walker, Mr. Symons, and Mr. Preece, too, spoke as if he had specially attacked the report of the conference. But that he had not done at all; he had made great use of the report, and he thought that that conference had done a very valuable piece of work. They had collected together all manner of details of destructions and of failures of lightning rods. The whole of the report is bristling with failures of lightning rods, so that he was at a loss to understand—no, he did understand—how they could say that rods never fail. They say that a properly constructed lightning rod never fails, because whenever a thing fails they always say there was something the matter with it. They generally say bad earth, but why a thing ought to have such extraordinary good earth he never could tell. What was the difference between one end of the conductor and the other? You stick three points at one end, and you want a lot of roots at the other end; suppose it were upside down, why not have the roots in the sky and the points down below? Why should one end have to be treated so very carefully, and the other end be left to itself? So far as protection is concerned, the points at the top and the three points at the bottom ought to do equally well. Of course it may be inconvenient to have the ground ploughed up, and things of that sort. You ought therefore to have a good deep earth; but, even if they had no earth, a flash ought not to split off from the conductor to such things as safes and gun barrels and rain water gutters. It did that because it met with obstruction—impedance—he did not care what they called it—a spurious resistance. They might call it resistance if they liked, but it was not what they ordinarily called resistance, it was like inertia. As regarded failures of properly constructed lightning conductors, he wanted to know from Mr. Symons—there would be plenty of opportunities for continuing this discussion in print—why the Hotel de Ville, at Brussels, was set on fire by a lightning flash, because if anything was well protected, according to orthodox principles, that building was so. He himself thought it was protected. When he said that a building was not completely safe, he did not mean, and had never thought of meaning, that lightning protectors are of no use; they are of very much use, but they may, and he believed do, occasionally fail. M. de Fonvielle referred to the great experience that Mr. Preece had had, and also to the experience gained in France of all sorts of conductors, telegraph posts, and things like that. It is true they did not fail much, but then a telegraph post, and an obelisk, and a lighthouse were the easiest possible things to protect. There was just one column, and if they stuck one conductor down there was not much chance of its spitting or doing much damage. It was not so easy to protect powder magazines or houses where there was escaping gas. If the lightning flash was only a little bit away from a leaden gas pipe, it would very likely fuse it and light the gas, and they would have the house burnt. Professor Forbes had asked him to say why he did not use one pair of knobs instead of two pairs of knobs to try the experiment. If Professor Forbes tried it with one pair of knobs, he would find that he could not do it at all. There must be two pairs of knobs somewhere. The speaker sketched the two knobs of a Holtz machine, and a supposed alternative path, and then asked somewhat pertinently how were they to get sparks between these knobs? If they were to put an alternative path to an air space, they must have another air space somewhere to enable them to do it, but it need not be done exactly as he had done it. He would not go further into that point now, as the discussion could be continued in print; but he might put his views briefly thus: These discharges are oscillating currents of extraordinarily great frequency—something like a million a second. For these currents it is only the outer surface of a rod that conducts; therefore its obstruction was due to the space surrounding the conductor, and it was not due to the material of the conductor. It is only the outside tube of the conductor that conveys any current, and therefore the conductor, whether iron or copper, did not get magnetized at all. It did not matter about its permeability, or about its conductivity much. The current is very great; even from an ordinary Leyden jar the current produced when discharged through an ordinary togs is about 3,000 amperes. The current in a lightning flash is, no doubt, enormous—he thought a million amperes for the time lasted. That it was very great was shown by the heating powers and the destructive powers it had, though its duration is so extremely small; and hence it is that the impedance being also very great they had this large amount of resistance and a tremendous current, and so they got a tremendous difference of potential at the end and the liability to spit off. Seeing that only the outer surface conducts, what is the good of the inside of the rod? It may be able to conduct some heat away, and so prevent melting, or it may not have time to do that. Probably there is no very great good in it, but if they were going to have a tube they had better have it spread out flat; or better still, have a strand of separated wires, or a series of wires about the size of telegraph wires. That was his view, but it was not authoritative. If what he said would be authoritative, and would go forth as a statement from that room, of course he would hold his tongue; but as it was, he simply said that which he thought true at the time. It was found that all the failures in the case of lightning conductors were due to the spitting off from them; were due to this high potential; were due to the impedance of the conductor—the obstruction of it; to the fact that it does not conduct easily away as they would expect—*not* due to the melting of it. Mr. Symons, in his report of the Lightning Rod Conference, gave a list of conductors which had been melted by the flash, and he apologized for the shortness of the list. No apology was necessary—the list was short because they very seldom got melted. If they analyzed those which Mr. Symons gave, they would find in every case but one that it was only the upper terminals which had been melted, not the full length of the conductor. There was only one case of complete destruction, and that was a bell wire, and, even so, it exerted a protective influence. So, then, we learn that when they are bell wires they are melted; but he did not want the wires which were to be put up to be of the thinness of bell wires. Iron buildings, as Sir William Thomson said, are practically safe for powder magazines, and the safest things they could make; but even with them some little care was wanted. The iron must be in absolutely good connection all through. If there were a gap left anywhere, there might be a spark in that gap. It might be only half an inch long or a quarter of an inch long; that would be quite sufficient to light gas and do all the damage. With regard to the action of sound waves in facilitating the discharge, he might just refer to an experiment first made by Dr. Guthrie, in which a resonant tube was taken, and the interior sprinkled with sand. An electric discharge occurring near the mouth of the tube, it was found that the sand was thrown into ripples, indicating that a series of longitudinal waves had traversed the tube—waves only about one millimeter long. These sound waves were due no doubt to the oscillating heat of the spark, and might certainly, as Sir William Thomson had suggested, precipitate a discharge in the neighborhood; but probably there were also other causes.

Mr. Preece commenced his reply by referring to the remarks which he had made with regard to mathematicians, and which had been so much criticised during the discussion. He explained that he would be far from wishing to undervalue the work of such mathematicians as were sure of their preliminary ground before they thrust their deductions upon the world. His remarks on this subject had really been introduced to try and check a kind of thing that had lately been growing to a very serious extent. Innumerable students had of late years been sent forth by our technical schools, and every year they found some of them armed with a smattering of mathematics, writing papers to our technical journals, in which they thrust upon the scientific (particularly the electrical) world conditions and conclusions arrived at by their mathematics, with a coolness and effrontery that were simply appalling. The true mathematician would never come to a conclusion, and never thrust his conclusions upon the world, unless he were sure of his ground; but the imperfectly trained gentlemen were too fond of throwing out conclusions without the least confirmation by experiment or anything else. As regarded the question of iron and copper, in answer to Sir William Thomson, he would say that most—in fact, all—of those lightning conductors of which he had actual experience were of iron, and always had been, as most of them knew who had read the reports he had written. He was a great advocate of iron. He thought the use of copper to the extent that it was used, introduced a needless expense into the erection of lightning conductors. His own impression was that every private house could be thoroughly protected according to the recommendations of the Lightning Rod Conference for at least a pound. Anybody could buy a coil of stranded iron rope, and if they took an iron rod about a quarter of an inch in diameter, with the finial Mr. Symons had referred to, he believed that they could safely protect their houses with lightning protectors for a few shillings, instead of now where copper was employed, indulging in the expenditure of a few pounds.

The President, having expressed the pleasure with which he, and he felt sure all, had listened to the debate, and having thanked Dr. Lodge and Mr. Preece for their part in it, said that he felt that it would be extremely important, if telephony were to become useful on a very large scale, to protect those using the instruments from the injurious effects of a thunderstorm perhaps far away. He was inclined to believe that the experiment that Dr. Lodge had performed was not exactly analogous to the lightning discharge. As Mr. Preece had said, the discharge was much more like the breaking down of the plates of a condenser. There was a question with respect to the alternation of currents. He would call Mr. Preece's attention to this, that even though there might not be millions of alternations per second, a great many of the effects of an alternating current would be produced by an extremely sudden current of very short duration—that the effects that had been observed were due to the very sudden change in the strength of the current. Now, the effects of a very sudden change in the strength of the current could be produced by a single spark, whether there was an alternation or not. So that a great number of the effects that Professor Lodge had observed, and in reference to which he seemed to think it was necessary to have an alternation several million times a second, would be

produced by a single sudden discharge of a millionth of a second. In conclusion, he considered it desirable that a very large number of conductors should be erected all over the country, and their presence would, no doubt, prevent to a large extent the occurrence of formidable thunderstorms.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Inquiry into the Madison Square Explosions.—Overhead Wires Coming Down; the Mayor and Board of Electrical Control begin to Chop.—Bids for City Lighting.—Collapse of the Callender Insulating and Waterproofing Co.

THE events of the past month have been of unusual interest to those directly and indirectly concerned in electrical industries. It has long been evident that New York is to be the battle ground of the overhead wire war, and the experiences of the metropolis will be taken as a criterion for the framing of laws and regulations by other municipalities.

Immediately after the explosion in the subway at Madison square, a month ago—the Mayor convened the Board of Electrical Control and invited the representatives of the gas companies to attend. In the course of the proceedings it was shown that the leakage in the gas mains averaged from 15 to 20 per cent., and this loss, besides fouling the atmosphere and causing explosions, must be paid for by the consumer.

An engineer from Pittsburgh stated that this leakage was due to the fact that the old gas companies used cast iron pipe with plug and solder joints, while the best construction is that used for all new work—wrought iron pipe with screw joints; but the enormous cost of placing new pipes for the 1,080 miles of gas mains on Manhattan Island is such that the gas companies find it more pleasing to the stockholders to repair leaks as they occur and substitute modern pipe whenever convenient.

Shortly after this meeting the Mayor called for information for the purpose of issuing orders to the Bureau of Incumbrances to remove poles and wires from the streets, when, greatly to the surprise of everybody, the Western Union Telegraph Co. secured the order from Judge Wallace of the United States Circuit Court (mentioned in the ELECTRICAL ENGINEER, for April) temporarily prohibiting interference by the Mayor and Board of Electrical Control, until argument could be heard upon a motion for a permanent injunction. The Western Union had remained passive for some time and such precipitate action was alarming because unexpected. Upon the hearing for an injunction, however, Judge Wallace vacated his previous order in so far as it related to the wires and poles in the streets, holding that all companies owning wires and poles in the streets are subject to reasonable police regulations of the state, and he holds that the laws with regard to the subways are just and reasonable. He ruled, however that the city had no control over the placing of wires and cables upon the elevated railroad structures. (An abstract of Judge Wallace's opinion will be found in this issue under legal notes.—ED.)

Upon the receipt of the official papers (April 16th), the Mayor issued an order to the Commissioner of Public Works, directing the removal of all wires and poles (excepting those upon the elevated structures) on Sixth avenue, from 23d street to 58th streets; on Broadway, from 14th street to 45th street; on 25th street, between Sixth avenue and Broadway; on 42d street, from Sixth avenue to Madison avenue. The several electrical companies received notice of this order and they were asked to shut off all current from the wires, but this was not done, and when the wires were cut by the Mayor's men, the sparks flew in some cases, and caused consternation among the crowds who were witnessing the work. The removal of the poles and wires is still going on, several streets being left in darkness, and many private consumers have been cut off. One death has so far been caused by falling poles, and many narrow escapes are reported, the employés of the city not being experienced linemen. As fast as poles and wires are taken down, they are removed to the city storehouse, the owners not being allowed possession.

The bids for electric lighting for the city were recently handed in as follows:—

The Brush company, 441 lights at 35 cents each a night outside of the subway district, and 65 cents where the subways are to be used; the East River company, 421 lights at 35 cents, and 68 cents in the subway districts; the United States company, 429 lights at 35 cents; the Harlem company, 89 lights at from 35 to 60 cents each; the North New York company, 28 lights at from 35 to 60 cents; the Mount Morris company, 878 lights at from 28 to 55 cents. The last-named company now furnishes only 18 lights, at the rate of 32 cents. Its bid is in competition with the United States, the Brush, the East River and the Harlem companies.

The Callender Insulating and Waterproofing Co., of 18 Cortlandt street, and Newark, N. J., has gone into the hands of the courts, Mr. J. R. Burdick being appointed receiver. Mr. George Callender, the secretary of the company, states that, for various reasons it was decided to wind up the affairs of the old company, so that a new corporation could be formed upon a basis more satisfactory for the handling of business; but on the other hand it is alleged that the competition in their line has been so great that business has been carried on at a loss for some time past.

NEW YORK, April 22, 1889.

PHILADELPHIA.

A New Edison Enterprise Excites the Curiosity of Berks County.—Telephone Legislation in Delaware.—The Philadelphia Electric Light Trust and the Edison Consolidation.—Councils Considering a Peremptory Removal of Overhead Wires.—New Street Lights.—The Franchise of the Frankford Electric Light Co.—New Patents Issued to Philadelphians.

RECENTLY the New Jersey and Pennsylvania Concentrating Co., in which Mr. Thomas A. Edison, is supposed to be interested, bought a tract of eight acres of iron ore lands near Bechtelsville, Berks county. O. S. Hussey, the superintendent of the company, erected a shed on the ground and stored within it all the plans for the additional buildings which are soon to be constructed. It is said to be the intention of the company upon the completion of its plant to experiment with a new electrical process for reducing ore. All the agents of the company have been very guarded about their statements, and such a strict watch was placed upon the premises that a deep veil of mystery has surrounded the entire proceedings. The strain proved to be too great for the curiosity of the residents of Berks county, and when the superintendent visited the shed recently he found that some one had broken into it and abstracted all the diagrams relating to the buildings. The thief evidently thought he was getting the key to one of Edison's most valuable discoveries.

An act has been introduced in the Delaware legislature at Dover, providing that every telephone company doing business within the state shall pay to the state treasurer for the use of the state the sum of $20,000. In case any telephone company doing business in the state shall fail or neglect to pay to the state treasurer the tax imposed for a period of 30 days after the same shall have become due, henceforth it shall be unlawful for such company so failing to pay to carry on its business within this state, and upon such failure or neglect to pay for the period aforesaid it shall be the duty of the state treasurer to issue a proclamation announcing failure or neglect, and if the company undertakes to do business after such proclamation it shall be fined $500 for each piece of business done.

In regard to the rumor that the Electric Light Trust is about to collapse because the Edison Electric Light Co. refuses to join the pool, Professor Marks, the supervising engineer of the Edison Electric Light Co., said: "I know it to be a fact that Henry Villard has secured for the German capitalists, whom he represents, absolute control of all the rights of the Edison Electric Light Co. in the United States. What use he will make of his power I do not know, but if he wants the trust to succeed he has the ability to accomplish his purpose."

A resolution to order the telegraph, electric light and telephone companies to remove all wires from overhead in the built up portion of the city, by October 1, 1889, was taken up by Councils Law Committee a few days ago. The general sentiment was that prompt action should be taken, but the matter was not disposed of.

The new electric lights along Diamond street west of Broad to the park has just been lighted for the first time. Each lamp is swung over the street on an arm projecting 15 feet outside the curbstone, so that the middle of the street will be much better illuminated than by the old plan of locating the lights directly over the sidewalk.

Councils Electrical Committee recently considered the ordinances granting privileges to the Frankford Electric Light Co. The main objection to the bill was that the provision for securing the city the five per cent. contribution on the company's profits was not sufficiently clear. The bill was amended on this point and reported back with a favorable recommendation.

The following list of patents were issued to citizens of Philadelphia during the week ending March 26, 1889:—

William C. Cranmer and S. W. Arnold, constructing underground conduits.

Stanley C. C. Currie, Philadelphia, Pa., assignor to United Electric Improvement Co., Gloucester, N. J., electric distribution by storage batteries.

Isidor Kitsee, Cincinnati, Ohio, assignor to M. Sulzberger, trustee, Philadelphia, Pa. voltaic battery (three patents).

Isidor Kitsee, Cincinnati, Ohio, assignor to M. Sulzberger, Philadelphia, Pa., secondary battery.

Rudolph M. Hunter, secondary battery.

PHILADELPHIA, April 18, 1889.

BOSTON.

Continued Interest in the Electric Railways.—The Overhead Wire Question Still Agitated.—Hearing before the Aldermen on the Petition of the West End Street Railway Co. for a General Overhead Conductor Privilege.—Affairs of the Telephone Companies Discussed at the State House.—The Elevated Electric Railway Scheme Again Before the Legislature.—Electric Light and Railway Notes.—Annual Meeting of the New England Electric Exchange.—The Collection of Patents in the Boston Public Library. Municipal Lighting.

THE electric railway is the agitating feature of electrical legislation at present. At the State House the Committee on Mercantile Affairs have under consideration a bill for placing electric wires underground, which brings in railway overhead and conduit wires, and several orders relating to telephone matters. The Committee on Manufactures have under consideration orders relative to giving gas commissioners powers in electric light matters. The Committee on Street Railways have before them elevated railway projects, operated by electricity, etc. The Boston aldermen are dealing with similar questions, and between them much interesting information is being brought out. The telephone people are the principal sufferers from the electric railway wires; telephone lines in the vicinity of the roads are seriously disturbed; there is such a noise from induction, the subscribers are pouring in complaints to the New England Telephone Co. every day.

Replying to a request for an opinion as to whether or not the board of aldermen has the power to grant to the West End Railway Co. the right to locate electric overhead wires for the running of its cars, and under what statute, if any, said power is given, Corporation Counsel Richardson has stated that if such power is conferred it is under section 5, chaper 31 of the acts of 1799; section 39, chapter 118, and section 4, chapter 413 of the acts of 1887.

The board of railroad commissioners in October, 1888, gave its permission to the West End Railroad Co. to make underground and surface alterations in certain streets named for the purpose expressly stated of establishing and maintaining its overhead electric system of motive power in said streets with poles and wires. It is a fair inference that it was the opinion of the railroad commissioners that the location, by their order, of electric overhead wires for the transmission of power for the purpose of running the cars of the company in the streets named in Boston was lawful.

The corporation counsel is of the opinion that the board of aldermen has the power to grant the right to locate electric overhead wires for the transmission of power for the purpose of running its cars in the streets named in its order therefor.

The matter has been referred to the committee of the whole board of aldermen.

The board of aldermen, as a committee of the whole, gave a hearing at City Hall at a recent meeting on a petition of the West End Street Railway for leave to establish an overhead electric system in streets where tracks are located.

Mr. Henry D. Hyde opened the case for the petitioners, saying that since the West End Street Railway took possession of the street railways, two years ago, it has endeavored to do everything possible to facilitate transportation, and now the managers believe that the overhead electric system is the best one for accommodating the public. He presented a memorial bearing more than 26,000 names in support of the petition.

Mr. Henry M. Whitney, president of the West End company, said that the West End company has honestly and fairly tried the conduit system, and finds its unsatisfactory. The people of Brookline, Brighton and Cambridge would never consent to give up electric cars and go back to horses. The danger of interference of the wires in case of fire has been exaggerated. It is useless to try to run two systems at once. There is no advantage in using electric cars while horse cars are run over the same tracks. What is good for one section is good for another, and the public would be benefited by introducing the overhead system throughout the city.

Ex-Mayor O'Brien said that if the petition is granted the problem of rapid transportation will be solved.

R. H. Stearns spoke in favor of the petition. In reply to a question from alderman Smith, he said he should have no objection to the company's placing a post in front of his store door.

Remarks in support of the petition and the need of a system of rapid transportation were made by ex-alderman Paul H. Kendricken, Hon. Halsey J. Boardman, Hon. R. Worthington, Hon. Liverus Hull, ex-alderman Charles H. Allen, Judge Baldwin, of Allston; John C. Paige, and William T. Van Nostrand.

On the 10th of April the aldermen, sitting as a committee of the whole, continued the hearing.

Mr. Moody Merrill said the people of Roxbury need more cars and a better system of transportation. He thought the overhead electric system would give relief, and he did not think an elevated railroad could be built and made ready for operation for several years. He thought there was less danger from the overhead system than from a conduit.

Mr. Isaac Farnham, an electrician, explained a model showing the operation of the double-trolley system. (Mr. Farnham has invented a most ingenious device to maintain a path for the trolleys at points where tracks intersect.)

Fire Commissioner Fitch said that the fire commissioners desire to protest most emphatically against the most sweeping invasion of the rights of the department and the interests of the city that has yet been attempted. He said that the firemen are brave, but it is not right to subject them to unnecessary dangers, and if the electric current of the railway system can throw down a ton of horseflesh—as it did yesterday—it is difficult to estimate the danger to the public. Even if there were no electric current, the wires would still be a source of great danger, for in narrow streets it would be impossible to raise the aerial ladder and other long ladders. Even if the railway had many men to cut wires, there would still be great danger, but the loss of a few minutes' time means in many instances, greatly increased loss of property and possibly loss of life. He believed that the fire department, from the commissioners down to privates, are earnestly opposed to the introduction of an overhead electric system by the West End Street Railway. There are already too many overhead wires in Boston, and none of them are placed where they ought to be.

Fire Commissioner Tobin said that the danger of erecting an overhead system of wires is immeasurable. In case of fire the wires would delay the raising of ladders, and in many instances would prevent the saving of life.

Mr. H. V. Hayes, an electrician, in charge of the mechanical department of the American Bell Telephone Co., spoke of the double-trolley system, and said that, although he had formerly considered it a physical impossibility, he has by investigation become convinced that it is the best system yet invented.

At the State House, on the 22d ult., the Committee on Mercantile Affairs had before it several orders relating to the telephone business. Representative Fottler, of Boston, presented a bill holding electric companies responsible for all damages caused by electric wires to buildings on which they may be placed. Hon. George A. Bruce, counsel for the Bell Telephone Co., questioned Mr. Fottler and criticised the bill. E. W. Burdett also criticised the measure as tending to make the electric companies do the business of insurance companies. He objected that so much of the bill was out of the scope of the order. It was an act of confiscation. Hon. P. A. Collin was also present and opposed the bill. Mr. Burdett gave figures from the last report of the Boston fire marshal to show that there is much unfounded apprehension as to the dangers from electric wires. Only seven-tenths of one per cent. of the fires were caused by such wires. There is great danger to electrical science and business from ill-founded popular apprehension. To Mr. McEnaney Mr. Burdett said that the idea that electric wires should be put underground was the worst error of all. Mr. Bruce said that there is great caution in attaching wires to buildings and that they are not attached without the consent of the owner. Mr. Fottler said he introduced the order from the private complaint of a large property holder in Boston.

After this, the committee took up the orders in regard to compelling telephone companies to furnish free service to cities and towns, and in regard to reducing telephone rates. Mr. Mellen, of Worcester, said that telephone companies should be required to make more detailed returns. He would have them put under such regulations as railroad corporations and savings banks. The Bell Telephone company asks for $10,000,000 capital, and it ought to give reduced service in return for what it gets. He had some interesting facts to lay before the committee regarding the relations of the company to the public. He moved that the matter be postponed and considered in connection with the Bell company's petition, and until he could collect further information. The public ought to have a fair show against this great company and ought to have all the statistics obtainable. Mr. McEnaney, of Boston, moved that the consideration of the two orders be postponed till the hearing on the increased capitalization of the Bell company. Mr. Bruce said that the telephone business of the state is conducted by the New England Telephone and the Southeastern Telephone companies. A bill to regulate rates would affect these companies and would affect the Bell company only indirectly as a holder of their stock. Those companies should not be mixed up with a hearing for the increase of the Bell's capital stock. The matter was discussed at length, and the hearing on the two orders was postponed to a date not fixed.

The Committee on Street Railways recently continued the hearing upon the petition of F. M. Ames and others for incorporation as the Boston Electric Elevated Railway Co. Warren S. Hill, an expert in electrical science, considered the New York elevated system as near perfection as had yet been reached. Mr. Hill thought the element of danger from electric wires would be lessened by having them carried upon supports such as were possible upon an elevated railway. Nathaniel J. Rust, one of the intending co-operators under the Ames petition, spoke of the necessity and advantages which would come from elevated rail-

ways, and declared that he had signed the petition in good faith and with full intent to act under a charter, should it be granted.

James F. Almy, of Salem, and Mayor Titcomb, of Newburyport, said that they had entered into this enterprise in good faith, and were ready to subscribe if a charter is granted. The hearing was adjourned.

On the 2d of April the Waltham city government gave a hearing to the Newton Street Railway Co. on its petition to operate an electric railway by the Thomson-Houston single overhead trolley system. It is proposed to run cars by electricity on a circuit from Waltham, West Newton, Newton and Watertown. Mr. Powers, on behalf of the New England Telephone Co., suggested that the double-trolley system be used. The representatives of the railway company answered that it is utterly impossible to use such a system on the proposed railway.

The Naumkeag Street Railway Co, of Salem, hopes to get electric cars running on its main Peabody system by July 4.

At Woonsocket, R. I., the board of aldermen has decided to grant its local street railway company a franchise to substitute electricity for horse-power. Woonsocket introduced the first electric cars run in New England, in 1887, but the service was not entirely satisfactory and a franchise was denied and the service discontinued after a three months' experiment. With the improved overhead system the aldermen are now willing to grant a full franchise, and the entire system will be equipped as soon as practicable.

The New England Electric Exchange held its annual meeting on the 8th of April at the rooms of the Boston Electric Club, 7 Park street, president P. H. Alexander in the chair. The following-named officers were elected: president, P. H. Alexander; secretary, H. B. Cram. These officers, together with Frank Ridlon, A. Robinson, and Y. Bradbury, constitute the board of directors. President Alexander, in his address, referred to the pleasant relations existing between the exchange and the insurance men. He stated that there had been for the year 175 applications for licenses; 150 had been examined, and of these 144 were granted certificates. Sixty-eight obtained a lower grade and four a higher grade than examined for, and six were rejected as totally unfit for the business of an electrician. In addition to the regular business there was a discussion of the "Insurance Requirements for Electric Lighting Stations," growing out of the fact that there had been considerable trouble of late in obtaining insurance on central stations. A paper was read by M. J. Perry, of Providence, upon "Economical Steam Plants for Electric Lighting Stations."

The new room of the patent collection in the Boston Public Library has been now opened. The old room having become overcrowded, it was found necessary to occupy the art room on the ground floor. The collection includes American, English French, German, Belgian, Australian and Canadian patents—in all 4,000 volumes.

The electric lighting of cities has become a question of much importance to their inhabitants. Investigations have recently been made as to the expense of lighting the streets of various cities by electricity, and it has been ascertained that Boston pays 65 cents each night per lamp, Lowell 55, Worcester 55, Springfield 60, Bridgeport 50, Hartford 54, Fall River 56, New Bedford 50, Providence 50, New Haven 50, New York 40, Albany 50, Newark 50, Philadelphia 47, Baltimore 50, Washington 65, San Francisco 66. Of these cities it will be noticed that Boston stands near the head of those paying the most for its electric lighting. In the cases above cited the work is performed by private companies. But there are towns which have their own electric plant, and to them the cost of such lighting is apparently insignificant. In Chicago it does not exceed 15 cents per lamp each night. In Portsmouth it costs 10 cents; Decatur, Ill., 13.7; Michigan City, 12; Topeka, 20; Lewiston, Me., 20. These figures may look alluring, and they undoubtedly do show that Boston has been paying too much for its electric lights. But they are by no means conclusive. Politics enter largely into municipal undertakings, and the figures given as to the cost of working city plants may safely be taken with much reservation.

BOSTON, April 16, 1889.

CHICAGO.

The Chicago Electric Club Secures More Commodious Rooms; its Meeting of April 15.—The Telephone Bill Hung Up in the Illinois Legislature.—The Central Union Telephone Company's Cogent Presentation of its Position.—Pennock in Chicago with his Primary Battery Scheme.—The Western Union Telegraph Company Sued for $10,000 Worth of Peace of Mind.—Death of Mr. Edward P. Allis; his aims for Industrial Reform.—Personal Mention.—The New York Conduit Explosions Discussed.—A Company with a Title Too Full for Utterance.—Electric Lighting in Japan.—Electric Light Contracts.

THE Chicago Electric Club, after a year or more of discussion, has finally decided to move into new quarters. It has been stated a number of times in the Chicago letter that the club was dissatisfied with its present quarters, and looked with envious eyes at the more fortunate organizations in New York and Boston. It seemed necessary in order to make the club meet the requirements of the members that its quarters should be located in a central part of the city. A search for rooms has been in progress for a year, but until within a few weeks nothing suitable could be found. It has now been determined to rent two floors in the High building on Adams street, which adjoins Kinsley's restaurant. A door will connect the club rooms with the restaurant, so that the members will enjoy the advantages of an unexceptionable cuisine. It is an arrangement which seems to meet the approval of all the members of the club. Already the membership is beginning to increase with the prospect of new quarters. It is expected that within a short time the members will number at least 200. The club rooms are to be elegantly furnished, and electric lights will be used throughout. It has been rather humiliating to Chicago electricians to sit in quarters lighted by smoky, flickering gas jets. At the meeting April 15th Fred De Land read a paper in which he reviewed at length the history of the club. The club has done considerable effective work under extremely unfavorable circumstances during the last two years.

The Eckhardt-Baker Telephone bill, the provisions of which have already been given in the correspondence from Chicago, remains in about the same shape in the Illinois Legislature. The chances are thought to be against its passage—a fact which is extremely gratifying to the Chicago Telephone Co. An attempt was made in the early part of the month to advance the bill, but as the requisite two-thirds vote could not be secured, the effort fell through. Those who had failed to force the bill ahead made charges accusing those who had disagreed with them with corruption, and a lively scene followed in the House. Members used language which scarcely reflected credit upon the body. It was also suggested that newspaper representatives who charged members with corruption should be excluded, but no action of this kind was taken.

A second attempt to take up the bill out of its regular order failed.

Senator Eckhardt introduced a bill providing that if the companies refused to operate under the proposed law they should forfeit their franchises.

The Chicago Telephone Co. has sent to the members of the Legislature a statement of its claims. Among other things, it says:—

"The rates now charged in Illinois are lower than those in many other states for facilities furnished. They are based upon the length of line, character of equipment, and facilities required in each case, and this company protests that any other fixed basis for rates at present would be impracticable, and could not fail to destroy this useful industry, or greatly retard its development. The average rate paid by exchange patrons of the Central Union Telephone Co. (which operates most of the exchanges and lines throughout the interior of this state) is about $3.49 per month, but this average rate would fall far short of covering the actual expense of furnishing telephone service in larger cities, like Chicago. The rates proposed by this bill are but a small reduction to each subscriber, but to the Central Union Telephone Co. this reduction is a great matter, involving the difference between moderate returns upon an investment and the impossibility of continuing the business at the prices named in this bill. The difference between existing business and residence rates is due to the fact that business subscribers use the telephone more than residence subscribers, and get more benefit from it at an increased cost to the telephone company for furnishing the service. The practical result of the bill would be to give business men, who use the facilities most, who receive the greatest benefit, and whose service entails a greater expense upon the telephone company, the same rate as the residence subscriber, who receives but comparatively little service and corresponding benefit. It would, in fact, be taxing the housekeeper for the benefit of the business man, by making the housekeeper pay a portion of the expense of the business man's service."

Can primary batteries supply current for incandescent lamps more economically and more efficiently than dynamos? George B. Pennock, of a primary battery company of Chicago, which bears his name, answers this query in the affirmative. The Chicago *Tribune* recently devoted considerable attention to the subject, and insinuated a negative answer, and stated that Mr. Pennock's great object was not to make installations of his system, but to dispose of stock in his company at $1 a share. Of course Mr. Pennock made an emphatic denial, in which he took occasion to state that the generation of electricity by dynamos was a complete failure, and that his system gave the only effective and economical incandescent lamps.

Professor Badt then took a hand in the controversy. He published a communication in which he proceeded to characterize Mr. Pennock's system in terms that will not tend to increase confidence in the inventor's good faith.

Mrs. Hannah Joseph has commenced a suit against the Western Union Telegraph Co. to obtain $10,000 damages. The amount she asks is to compensate her for a night of suspense and worry. Her husband telegraphed her that he was not coming

home one Saturday evening. The message was not delivered, and her worry about her husband's safety, she alleges, seriously impaired her health.

E. P. Allis, of Milwaukee, known to electric light men throughout the country, died April 1st. He was proprietor of the Reliance Iron Works of Milwaukee. Mr. Allis's property was estimated at several millions. This interesting paragraph appeared in his will: "It has long been a cherished idea of mine to convert these works into some sort of a co-operative or profit-sharing institution, but the proper method and time have never been clear for me to do so with a surety of success. I believe such an arrangement is the proper one for all concerned in its management and operation, and that it will soon be feasible, and I commend its careful investigation and, at the proper time, its adoption by my trustees." No public bequests are made, and in explanation of this the testator says: "In this will I have made no outside bequests, deeming the size of my family and the central idea of a great and publicly beneficial Milwaukee industrial institution with ample means and the family name as precluding and taking the place of any other bequests."

F. N. Armour, who has represented the C. & C. Motor Co. in Chicago, has been appointed agent for isolated plants for the Edison company. A. H. Lewis will hereafter represent the C. & C. company.

Chicago electricians have been considering with interest the question of explosions in the New York subways. In view of their experience with Chicago conduits their opinions have been solicited. The general belief seems to be that the explosions are caused by spontaneous combustion, though in the case of the explosions in the Edison man-holes the spark was traced to the wires. The Edison company proposes as a remedy to put uncorked bottles of chloroform in the man-holes.

A company bearing the following formidable title was incorporated recently: United States Vogel-Kazophone-and-Electrical-Micophone-Trumpet-Acoustic-Electromotor-Power-Musical-Far-Distance-Loud-Speaking-Transfer-Instrument Company of Chicago. The incorporators are William Vogel, Adolph Gray and Richard H. Dakin. The capital stock of the company is $60,000,000. What the company proposes to do can only be conjectured. The organizers of the many-worded corporation refuse to disclose in any way what their instrument is or what their intentions are.

The Western department of the Excelsior Electric Co. has secured the contract for furnishing the arc light plant for St. Joseph, Mo.

Lieutenant Yoshie, one of the staff of a Japanese Prince who is visiting America, was recently interviewed in Chicago concerning the extension of electric lighting in Japan. He said the lights were extremely popular. He made one point which will interest the writer of the next paper on electric light and fire risks. He said while incandescent lights were more expensive than other illuminants, still the increased cost was not considered an objection, as the difference in the prices was looked upon as a premium paid for a sort of insurance.

Frederick Sargent, the general superintendent of the Chicago Edison company, has resigned to accept the position of chief mechanical engineer and superintendent of construction of the Edison United Manufacturing Co. of New York. Mr. Sargent's friends have given several dinners in his honor, and presented him substantial tokens of their esteem.

George Cutter, a well-known electrical engineer who has been connected with the Thomson-Houston company, of Chicago, has resigned his position and has started a business of his own. He will handle specialties, and will engage to a limited extent in the supply business.

The contract for lighting Springfield, Ills., has been awarded to A. L. Ide, of the Ide Engine Co. A company to perform the work has been incorporated by A. L. Ide, G. N. Black and S. D. Shales. The capital stock is $100,000.

CHICAGO, April 12, 1889.

MONTREAL.

Wiggins's Predictions.—The Canadian Underground Wire Bill Rejected by Parliament.—The Litigation of the Telegraph Companies.—Lachine to have Electric Lights and Fire Alarm.—Mr. Frank Redpath's Private Lighting Plant.—A Gibson Storage Battery in the Bank of Montreal.—Personal Notes, Including Mr. Brown.—Electric Light Notes.—A Westinghouse Plant at Hamilton.—New Edison Contracts.

READERS of the ELECTRICAL ENGINEER, doubtless have all heard of Wiggins! the irrepressible Wiggins! He promised us for the early spring, the most severe cyclonic storm ever experienced. The cyclone has not as yet kept its engagement. This, however, does not prevent Wiggins's further predictions. His latest fad, is that the telephone and telegraph wires and wire fences have an evil influence on the course of storms, centering the storms where the wires are thickest. That is not all; the influence the wires have, has caused a cessation of the northern lights. Wiggins may deprive us of our cyclones, and give them to our more favored neighbors, but the northern lights—we must have our northern lights at any cost.

The Underground bill, mentioned in last month's letter, has been presented before Parliament, and was reported on adversely, and thrown out, on the ground of provincial rights previously conferred. The Toronto City Council have in accordance with the views thus expressed by parliament, enacted a by-law putting the control of all telegraph, telephone and other wires under control of the Common Council.

The suit of the Great Northwest Telegraph Co. *vs.* the Montreal Telegraph Co. is in progress. No decision being as yet reached, it seems probable that the holders of Montreal Telegraph Co.'s stock will be forced to accept a lower rate of interest, for in case they refuse to do so, the Great Northwest company can forfeit their lease, thus leaving the Montreal company without a connecting line to the states; they will thus be forced to divide the small business now being done, between three companies instead of two as now.

The citizens of Lachine, a suburb, and summer resort for Montreal people, are desirous of having modern improvements, and are preparing to put in a fire alarm and electric light system.

Mr. Frank Redpath, of Montreal, an enthusiastic electrician, has been for some time lighting his house by electricity, driving the dynamo by means of a gas engine. He has recently added a Gibson storage battery outfit.

The Bank of Montreal has also been supplied with a system of Gibson batteries by Mr. Lawson, who was formerly with the Edison company, but now located at Montreal, in a general electrical business.

Mr. W. R. Kimball, formerly with the Royal Electric Co., has severed his connection there, and is now doing a general electrical business, with head-quarters in Montreal.

Mr. Brown, of "death dealing current" fame, has recently been in Montreal, on a mission of benevolence, enlightening the citizens as to the dangers lurking in the electric light wires, and especially in the alternating current wires, put up under the supervision of the city electrician and insurance inspector. The Montreal public will hardly realize how self-sacrificing Mr. Brown is, to have gone so far from New York on his disinterested mission. It is an open secret, known here I believe, to some, as it is generally in New York, that Mr. Brown goes on his missions of love for nothing else than the good of mankind, and in so doing feels amply remunerated.

The Royal company report the sale of a 100-light incandescent plant for Norris's mill at St. Catherine's, 30 arcs and 500 incandescents (alternating) for a central station at St. Johns, P. Q., also 1,000 lights alternating at Quebec, P. Q.

The East End station, a part of the 600 arc lights' increase in the city lighting, is well under way. The motive power will consist of two pairs of 16 x 36 Brown engines of a total capacity of 600 h. p. The addition to the main station will consist of a pair of 18 x 42 Brown engines of 500 h. p. capacity. The 600 lights are to be ready first of July.

The Westinghouse company are putting in a 500-light alternating plant at Hamilton, Ont.

The Edison company report the sale of central stations as follows:—

Brandon, Man., 480 lights, Pembroke, Ont., 640 lights, Woodstock, N. B., 320 lights, Chatham, N. B., 320 lights, and to the Ogilvie Milling Co., Winnipeg, 160 lamps, Canadian Pacific Railway steamer *Manitoba*, 240 lights. Increase in steamers *Alberta* and *Athabaska*, 57 lights each, Albert Weiner, Copelton, Quebec, 160 lights, Copelton, Quebec, Chemical Works, 120 lights, increase Potter Mfg. Co., Sherbrooke, Quebec, 80 lights.

MONTREAL, April 22, 1889.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall street, New York city.*

ELECTRICAL COURSES IN COLLEGES.

[105.]—In answer to a communication in your March number would say, that evidently Mr. D. C. Jackson has not fully looked up the matter of electrical engineering departments at certain technical colleges, at least not Cornell University, or if he has, he surely has made a mistake and given wrong impressions in his communication. It is a known fact that certain *practical* electricians, as they call themselves, are continually harping about

the worthlessness of the course of instruction given in electrical engineering at technical colleges, and give everyone the idea that the students only obtain a theoretical knowledge of electricity and have only a vague idea of anything that is practical in the electrical world. A more erroneous impression could not be had. It was not the "*fashion*," but because of the *necessity*, that courses of this character were founded in the technical colleges.

Mr. Jackson says that: "the course in electrical engineering" at these colleges, "is tacked to the department of mechanical engineering or of physics, and in consequence either does not receive due attention or active practical treatment."

Such is hardly the case, for a more practical course is not to be found at Cornell University than that of electrical engineering. Having a full corps of practical electricians to give instructions and an equipment containing dynamos, lamps, motors, etc., of nearly all known systems; several complete outfits of which are in actual operation. A very large field of practical work is open to the students in this course. A part of the junior and the entire senior year is devoted to practical electrical work.

The reason the electrical engineering course is generally taken in connection with the mechanical engineering course for the first two years is because the preparation is similar for both. To be a good electrician one must have a thorough knowledge of higher mathematics, physics and mechanics, and, in fact, all that make up a good mechanical engineer. For this instruction why should he not have similar training to that of the mechanical engineer? It is true, he should be a specialist—" an *electrical* engineer"—and he obtains this specialist's study at the technical college in the last two years.

This field of work is new, and it takes time to perfect the course of instruction; but even at the present day the technical colleges are doing more to turn out useful practical electricians—men having higher aims than to be dynamo tenders or line men —than could be done in any other way. If, instead of finding fault with what is being done, such able electrical engineers as Mr. Jackson would show a greater interest in making the course of training what it ought to be, all would be benefited thereby.

FRANK C. PERKINS.

Cornell University, Ithaca, N. Y.

ELECTRIC LIGHT CONSOLIDATION IN AUSTRALIA.

[106.]—I believe that your columns are open to any appeal for truth and justice, more especially in the interests of electric lighting, and for that reason I ask you to publish a protest against the terms of an article appearing lately in the columns of the English *Electrical Review* for February 1, page 129, on the subject of the Australasian Electric Light, Power & Storage Co., Limited.

It certainly seems a pity that the writer of that article should not have taken the trouble to inform himself somewhat more accurately before he set forth in black and white statements which are undoubtedly prejudicial to the interests of the shareholders in a deserving industry and of benefit to no one, being inherently rash and fallacious. He states, for instance, that the Australian Electric Co. was wound up some months ago, and that the assets represented formerly by the 18,000 shares in that company, had ceased to exist. This statement is untrue. The Australian Electric Co. is not yet actually wound up. A new company with more extended powers and increased capital has been registered with the object of purchasing and taking over the business which will consist, practically, of the same shareholders and will be the same company under another name and with more extended powers. The position of this little company is better, stronger and more full of promise than it ever has been yet.

Again, the writer of the article in question would imply that the directors are speaking without warrant when they talk confidently about the central lighting station. Some 2,500 16 to 20-c. p. lamps equivalent to over 3,000 10-c. p. lamps, such as are ordinarily used in the best lighting stations in England, are now being rented from the company at full prices. Fresh customers are being secured almost weekly, and it will not be long before the full capacity of the lighting station will be reached. This may be taken at about 6,000 Swan-Edison 40-watt lamps. The actual value of the land, buildings and plant may be put down at about £20,000, with a capacity for yielding a net revenue of over £4,000 per annum in well established contracts, many of them of several years duration. To ask for £40,000 in shares, not in cash, in a new company for such a business as this connected with some of the best business men and firms in the colonies, is surely not an excessive demand.

Another statement made by the writer in the *Electrical Review*, who seems quite independent of all authority for what he says, is that the Electric Light and Power Supply Co., of Australia, will not amalgamate, but intends to fight. Now, this is so far from being the policy of the company in question that the directors on both sides are personally on extremely friendly terms, and the Electric Light & Power Supply Co. has already commenced the policy of amalgamation by joining in the formation of a new company called the "Union Electric Co.," and the directors of both companies forming the union have openly stated their desire at an early period, to further amalgamate with the new Australian Electric Co., Limited, and its friends, quite irrespective of the particular system or systems to be employed. They consider that this latter point should be determined solely by the merits in point of output, workmanship and economy of the different systems which are now available. Such a combination as is here suggested, would be as strong, probably, as any that has yet been brought about in electric lighting. Does it not then seem rather hard that a scientific paper of the character of the *Electrical Review*, should give its sanction and tacit approval to such an article as the one alluded to, in which the writer most unjustifiably makes statements which are not only untrue in themselves, but which he could have corrected with the information at his disposal in London at the time he wrote them.

Trusting that you will oblige the Australian Electric Co. by the insertion of the foregoing.

I remain, Sir,

Yours faithfully,

F. C. ROWAN,

General Manager in Australia of the A. E. L. P. & S. Co., Limited, and late Managing Director Australian Electric Co., Limited.

Melbourne, March 15, 1889.

LITERATURE.

Economic Value of Electric Light and Power. By A. R. FOOTE, Cincinnati: Robert Clarke & Co., 1889.

THIS book is addressed to investors, the managers of industries, students of industrial methods, and to municipal authorities rather than to electricians. Mr. Foote is far from claiming expert knowledge of electricity or of its application to the purposes of light and power. He is a student of industrial economics, and in the volume under notice directs his attention and the reader's to the economic aspect of the part which electricity is to fulfill as a means of distributing and utilizing energy for the production of light and power.

His argument is two-fold. First, that electricity will at no distant day supersede all other means for transmitting power over municipal areas; and, second, that the development and use of electrical distribution, whether for private or public service, should be left to the untrammeled employment of individual or associated capital and enterprise; that is, free from state or municipal competition or control.

Electricity is to be "on tap," as one might say, throughout all cities and towns for light in all streets and houses, and power for all machines; but the full economic benefit of this common supply of energy can be secured to the whole community only by the absence of all state or municipal ownership or management in providing it.

It is gratifying to electrical engineers, and to the owners and managers of electric lighting and power plants, to find both these positions maintained by a writer who looks at the whole subject from an outside point of view. Probably, however, there are not a few readers of the first-named class who may feel disposed to modify some of Mr. Foote's unqualified expressions of confidence in the capability of the electrical engineering art of to-day to vanquish all problems of distribution.

While witnessing the remarkable advance in methods of long-distance supply that has been achieved during the last five years, and the daring undertakings based upon them now in progress, it can scarcely be doubted that electricity will ultimately become the chief means of illumination and of the distribution of power; but the electrical engineer may still feel inclined to withold his assent from Mr. Foote's confident assertion that "the demonstration is now complete that all the illuminating and power service of a city can be performed from one central station." We assume, of course, that he means any city, or large cities, and we venture to think it would be well to await the results of operating some plants now constructing, notably the huge Deptford station for supplying a large section of London, before announcing a "demonstration." The economic value of concentration, *i. e.*, the superior economy of wholesale over retail, is undeniable, but, while we have no notion of recording an opinion against the ultimate employment of the single station plan of distribution in large cities, it should be borne in mind that sufficient experience in very wide distribution on a large scale has not yet been accumulated to warrant unqualified confidence in its superiority to a district system.

Whatever electrical engineers may think of the author's views upon the proper relation of municipal governments to the business of general electric supply, few, if any, dissenting voices will be found among the owners of central station lighting and power plants now in operation, except, perhaps, as to his second proposition on the subject, to wit: that a municipality should grant the privilege or franchise to but one company. All will agree in commending the suggestion that no city or town should

own and operate a light and power plant, but when it comes to shutting off or out all companies but one, the question very likely to arise in many cities now supplied by several companies would be, which shall be "in" and which "out"? Mr. Foote would not only confine the service of a city to one company but would "eliminate from the grant all needless restrictions." The word "needless" gives much elasticity to the phrase, and it may fairly be inferred that the author would not regard as needless some control of service charges on the part of a municipality granting a monopoly of electric lighting and power supply. It would seem, moreover, that some degree of supervision or regulation of line construction ought to be secured to municipal authorities. "Electrical law and order," to use the happy phrase of Dr. Schuyler Wheeler, is imperative in future construction of lines, whether overhead or underground; and we fear the golden age has not yet fully arrived, when enlightened self-interest alone will prevent the further employment of inadequate and disorderly, that is, cheap, methods by some of the exploiters and promoters of electrical enterprises.

Mr. Foote has included in his volume his paper on "Municipal Ownership of Commercial Monopolies," read before the National Electric Light Association, at Chicago, in February, where it attracted well deserved attention. He has also reprinted a number of articles and papers by various hands and extracts from electrical journals bearing upon several aspects of electrical industries related to the theme of the book. In its general drift the volume is, we think, in harmony with the views of professional electricians as to the scope and power of their art to deal with light and power, and consonant with the most enlightened opinion in respect to the relations of municipal governments to industrial enterprises. It is perhaps to be regretted that the author has chosen to present his views in so sententious and aphoristic a style, a method of writing ill suited to elucidation or argument on so practical a theme as the economic aspect of electric light and power. Few will dispute Mr. Foote's numerous maxims, but they bristle on every page, and detract from the sobriety befitting the subject of the book.

Notes.

Turning Lathes: A Manual for Technical Schools and Apprentices. A Guide to Turning, Screw-Cutting, Metal Spinning, etc., edited by James Lukin, B. A., is a small volume that ought to find its way into the hands of young amateur workmen as well as of the students and apprentices referred to in its title. The work is clearly meant for beginners, and is extremely elementary, so much so indeed, that most apprentices might at first be inclined to resent being told what a mandrel or a headstock or a chuck is. But let them read on and they will learn much and enjoy the book as well as benefit by the study of it. They will learn fully and accurately some things that they have but partially known or understood, and will find reasons or explanations which they may have failed to receive from their superiors in the workshop. The book is fully illustrated with uncommonly good cuts. The publishers are E. & F. N. Spon, of New York, and the price is $1.50.

Dr. Leonard Paget has in the hands of publishers, a book entitled, "Dynamo Construction," the subject-matter of which has special reference to the construction and operation of alternating current dynamos and motors. He also has in hand, not yet ready for the publishers, however, a book entitled, "Graphic Arithmetic," directed particularly to the solution of electrical problems that are difficult and some times impossible to solve by ordinary arithmetical methods. This work is directed to the graphical solution of such problems.

Berly's Universal Electrical Directory for 1889, Wm. Dawson & Sons, publishers, London, has been materially increased in size. It contains 49 more pages than the edition of 1888. This work has now become familiar in electrical trade circles throughout the world. The especial purpose of the editors and publishers is to produce a trade guide excluding all technical matter, tables, formulæ, etc., and making it of the fullest value to manufacturers, dealers and electrical and mechanical engineers generally, as a purchaser's directory.

CATALOGUES AND PAMPHLETS RECEIVED.

The University of the City of New York. Catalogue and Announcements, 1888-9. The summary of the University instructors and students for the year is as follows:—Arts and Sciences: Professors, 24; Lecturers, 8; Students, 181. Medical School: Professors and Lecturers, 55; Students, 627. Law School: Professors, 3; Lecturers, 8; Students, 107. Totals: Instructors, 98; Students, 915; in all, 1,018.

Steam: Its Generation and Use. Under the foregoing title the Babcock and Wilcox Co. issue a neatly bound and handsomely illustrated octavo volume of 120 pages, containing a full exposition of the principles of operation of their boilers, with detailed and illustrated descriptions of their construction; tests of many of their outfits from the records of the owners of them; and a catalogue of the manufactures of the company. The work of this company has achieved a high standing among engineers and manufacturers; and all who are interested in the purchase or operation of steam plants will find full information of the peculiarities and excellences of their boiler construction in the volume above-mentioned. This latest edition contains much new matter, together with information that has been hitherto found only in detached publications and now brought together conveniently.

The Woodhouse and Rawson Electric Supply Co., of Great Britain, Limited, send us the second edition, revised and enlarged, of their Contractors' Electrical Supplies. The Woodhouse and Rawson company takes nothing less than the world for its field, and judging from the list before us aims to omit no branch of electrical application from the lines of apparatus and supplies which it offers to furnish. The range of the catalogue may be inferred from the statement that it includes dynamos—direct and alternating—motors, arc and incandescent lamps—even steam engines at one extreme—and the most insignificant items of domestic service supplies at the other. Between these limits are included about everything electric known to the practical arts, embracing many specialties of the Woodhouse and Rawson company in the various departments of their manufacture and trade.

We have a pamphlet from the Sperry Electric Co. of Chicago, which courteously salutes the reader with a "Good Morning" in its opening page and takes leave of him with "Good Night" at the foot of the 39th page. The intervening pages, while filled with much interesting matter, setting forth the advantages of Mr. Sperry's system of electric lighting are hardly likely to tax the brain of the reader from dawn to nightfall. Mr. Sperry has achieved some distinction in the field of electric lighting, and in the sheet of illustrations accompanying the circular of the Sperry Co. shows a dynamo of several peculiar and interesting features of design. Very strong claims of superiority over all existing arc-lighting systems are presented in respect to dynamos, regulators, lamps, switches, and every other feature.

The Telegraph Cypher Code and Catalogue of the Page Belting Co., Concord, N. H., comes to us in a new edition for 1889. The pamphlet includes, in addition to a catalogue of rubber and leather belting made by the Page Co., a series of practical rules for the purchase and use of belting, information upon the kinds and grades of belting to use for different kinds of work, and a cypher telegraph code for the use of customers in ordering.

NEWS AND NOTES.

THE WESTON ARMATURE PATENTS.

PATENTS Nos. 401,668 and 401,669, issued April 16th to Mr. Edward Weston, assignor to the United States Electric Lighting Co. (now leased to the Westinghouse Electric Co.), are apparently of very much importance to all makers or users of dynamos and motors or inductive generators, whether primary or secondary. The published announcement of the Westinghouse Electric Co. of its intention to deem as infringers of these patents all who make, sell or use dynamos or motors "provided with sectional armatures built up of iron plates, which are separated by interposed insulating material," probably concerns a very large portion of all the manufacturers of electric lighting and power apparatus in the country.

The matter is of such obviously general interest that we give below some extracts from the specifications of both the Weston patents and the claims entire:—

The drawings of both patents are identical, and show a drum armature in longitudinal section, having a wooden core surrounding its shaft and alternate discs of iron and insulating material upon the core.

The specification of patent No. 401,668 contains the following:—

"My invention relates to dynamo or magneto-electric machines containing cylindrical armature-cores wound longitudinally with conductors, which are caused to move in a magnetic field at right angles to the lines of force.

"The invention consists in a novel and useful construction of said cylindrical cores, whereby the circulation of induced currents is effectually prevented and the process of manufacture facilitated and greatly cheapened. These objects I attain by constructing the cylindrical core partly of magnetic and partly of non-magnetic material, the former being in the form of rings or discs, which are strung over a central hub or cylinder of wood or similar insulating substance, and prevented from contact with one another by interposed rings or sheets of insulating material."

The claim is as follows:—

"In a dynamo-electric machine, the combination, with the shaft, of a cylinder or hub of insulating material secured thereon, iron plates or rings strung over said hub, and plates or sheets of insulating material interposed between said rings, these parts being constructed and combined in substantially the manner set forth for the reception of the coils."

Patent No. 401,669 is broader in scope. From the specification:—

"My invention relates to electrical apparatus in which the coil or coils for the development of electric currents by inductive action is formed by winding an insulated wire or conductor around a core formed of magnetic material.

"Primarily the invention relates to magneto or dynamo-electric generators, or, in other words, to machines in which the magnetic core, wound with an insulated coil, is moved with reference to a magnetic field or the field moved with reference to the core in such manner, in either case, that the lines of magnetic force will be cut by the conductors at right angles, or as nearly so as practicable; but the invention is also applicable to other forms of electrical apparatus in which use is made of a magnetic core wound with an insulated coil or coils in which currents are developed by inductive action, and in which, in other respects, similar electrical conditions obtain to those met with in the ordinary form of dynamo-electric machines. In all such machines where the coils wound on an iron core are subjected to inductive action by their movement with respect to the lines of force, or

conversely, it is obvious that the same inductive action tends to generate currents in the body of the core itself, and this would occur if the core were formed of a solid mass of iron, or if it were so constructed as to present closed paths in the body of the material composing it parallel to the convolutions of the coils. Such development of currents in the core would obviously involve a waste of energy, and it would also operate injuriously by heating the core and coils, so as to render their continued use difficult or impracticable.

"My invention consists in a novel and useful construction of such cores, whereby the injurious results due to the generation of induced currents in the body of the core are avoided, the process of manufacture facilitated and cheapened, the mass of iron in the core more effectively increased, and its magnetic continuity in the direction of the lines of force traversing it more nearly preserved. These objects I attain by constructing or building up the core of alternate sections of magnetic and insulating material, by preference using a number of discs or plates of iron, arranged at right angles to the direction of the coils wound upon the core, with rings, sheets, or plates of insulating material interposed between them.

"Though described in connection with a core cylindrical in its general configuration, it will be readily seen that the invention applies equally to other forms of cores—as, for example, the ring, or annular cores now in use in machines of the Gramme type.

"I do not here claim the combination, in a dynamo-electric machine with the shaft, of a cylinder or hub of wood or other insulating material, iron plates or rings strung over said hub, and plates or sheets of insulating material interposed between said rings, inasmuch as this feature is the subject-matter of my application for letters patent filed September 22, 1882, Serial No. 72,475, of which my present application is a division."

I am aware that cores have heretofore been made with air-spaces between the several magnetic sections, and also that cores composed of bundled wires have been used, and I do not claim, broadly, herein a sectional or compound core; but

What I claim is—

1. A core for electrical generators operating by inductive action, composed of alternate sections, plates, or discs of magnetic and insulating materials, in combination with insulated coils wound thereon, as set forth.

2. A core for electrical generators operating by inductive action, composed of iron plates, sections, or discs, with interposed plates or sections of insulating material, in combination with insulated coils wound thereon at right angles to the planes or lines of the insulating sections, as set forth.

3. A core for electrical generators operating by inductive action, composed of iron sections, plates, or discs, with interposed plates or sections of insulating material, in combination with means for binding and holding the same together, and insulated coils wound thereon at right angles to the planes or lines of the insulating sections, as set forth.

THE TELEPHONE.

AT the meeting of the newly elected board of directors of the American Bell Telephone Co., Mr. John E. Hudson, who has been general manager since the retirement of Mr. Vail, five years ago, was elected president, succeeding Mr. Howard Stockton, resigned.

IN the Tennessee Legislature, on the 9th of March, a bill was introduced, which proposes to regulate the charges for telephones. The rate fixed in the measure is $36 per annum.

On the same date, in Texas, the clause in the charter of the city of Fort Worth, granting the city authority to regulate telephone charges, was eliminated in its passage through the House of Representatives.

ON the 11th of March, the bill providing a $3 per month rental for all telephones, failed to pass the Arkansas Legislature.

THE Hamilton bill, to regulate telephone charges in New York City, was defeated in the New York Assembly, on the 27th of March.

IN Missouri there have been 18 telephone bills before the present legislature. The rate bill is the only one that has made much progress. It would reduce monthly telephone rentals to $4 and toll charges to 15 cents.

A CASE involving a conflict between electric street railways and telephone companies, in regard to their respective rights to earth and air on city thoroughfares, was decided at Akron, Ohio, last week. Judge E. H. Green refused to grant the Central Union Telephone Co. an injunction restraining the Akron Electric Street Railway Co. from extending its line in the city. The telephone company claimed that induction from the electric railway wires makes it impossible for many of its subscribers to use their instruments.

A HEARING on the petition of the American Bell Telephone Co., for leave to increase its capital stock from $10,000,000 to $20,000,000 was held before the Committee on Mercantile Affairs of the Massachusetts Legislature on April 18. There were present besides Messrs. Bruce and Collins, counsel for the telephone company, Messrs. Forbes and Blake, directors; E. J. Hall Jr., general manager, and Angus S. Hibbard, general superintendent of the American Telephone and Telegraph Co., Stephen M. Weld, Henry L. Higginson and others. No remonstrants appeared.

In the course of the argument for the petitioners it was shown that upon the organization of the company (as the National Bell Telephone Co.) in the year 1877, the capital of $450,000 was deemed ample, but the development of the business necessitated an increase to $850,000 in 1879, and the year following the Legislature was asked to grant a charter for a capital of $20,000,000 but the amount was cut down to $10,000,000, under which the company has operated up to the present time. But the enormous development of the business, the necessity for extensions, the purchase of valuable patents, the cost of renewals, and the construction of the long-distance lines require a further addition to the capital invested. The company has spent $2,337,856 up to Jan. 1, 1889, for the construction of the long-distance telephone system, and when further capital is subscribed it is the intention of the company to extend very greatly its long-distance lines. The new work now laid out and actually building—that is, the line from Boston to New York via Providence and the line from Philadelphia to Washington—will cost about $600,000, and other contemplated extensions will require the expenditure of several millions of dollars within a comparatively short time. Something over $2,000,000 will be needed to take up the outstanding bonds payable in a little over a year, and, in round figures, $800,000 will be needed for the new building now in process of construction, a building which the requirements of the business render absolutely necessary. The cost of the long-distance lines with a capacity of 100 wires, averages $5,000 per mile. An additional line is being built from Boston to New York via Providence, and in round numbers it was contemplated to spend from $7,000,000 to $8,000,000 within the next four years.

Francis Blake said that there was no difficulty whatever, in his opinion, in communicating by telephone between Boston and Chicago, and that this view had recently been very strongly corroborated by some experiments made by Professor Cross of the Institute of Technology. That while there was a theoretical limit to the distance the human voice could be carried telephonically, there was practically no limit. Illustrating this, he said that scientists had shown long before Bell invented the telephone, that the transmission of speech by means of electricity was theoretically impossible, but nevertheless Bell had shown it to be practically a possible thing.

Mr. Blake was asked what improvements had been made in transmitters since the first one was invented. He said that the first transmitter is now known as the Bell receiver or hand telephone. Using this as a transmitter in his house, and talking to his laboratory, he had been enabled to make his assistant hear him when at a distance of three feet from the receiving instrument. Using the latest form of transmitter and the same receiving instrument, over the same length of line, he had found no difficulty in making his assistant hear him when the latter was 50 feet from the instrument.

Mr. Angus S. Hibbard, general superintendent of the Long-Distance company, stated that the business of the pay stations very nearly doubled every month, and that although the second line between Boston and New York was necessary to prevent interruption of communication in the event of storms and accidents, it is also necessary to meet the requirements of the business.

Henry L. Higginson, of the firm of Lee, Higginson & Co., appeared to state the advantages which he derived from being able to communicate verbally with his correspondents in New York. He said that it differed materially from communication by telegraph, inasmuch as it afforded the opportunity for a "give and take" conversation, and that just before coming to the state house he had, by means of his long-distance telephone, concluded a very important commercial negotiation which he would not have been willing to trust to the telegraph, and which could not have been carried on by letter, except with great loss of time. He was very certain that the business interests of the country required that this service should be very greatly extended, and that it would be a very great advantage to be able to talk with Chicago as freely as one now talks with New York, Philadelphia and other cities.

There being no more witnesses for the petitioners the chairman asked whether there were any remonstrants who desired to be heard. This question was asked several times, but no one appeared who desired to speak. The clerk of the committee stated that the hearing had been extensively advertised in the newspapers of all the principal cities of the commonwealth.

General P. A. Collins then made a brief closing argument, in which he said that it must be remembered that although the American Bell Telephone Co. was now prosperous the telephone had not by any means always been remunerative. Five years elapsed after the invention of the telephone before any dividend was paid. He said that the company was a Massachusetts corporation; that the money invested in the enterprise was Massa-

chusetts money; that the stock was held in Massachusetts and paid taxes in Massachusetts; that the business was founded upon patents which were the result of the ingenuity and skill of citizens of Massachusetts, and that here in Massachusetts and under its laws the company sought the privilege of further extending the business.

The hearing then closed.

COLLEGE NOTES.

Massachusetts Institute of Technology.

Entrance examinations for 1889 will be held at the Rogers building, 187 Boylston street, Boston, Mass., on Thursday and Friday, May 30th and 31st. A second series, for those unable to be present at that time, will be held on Sept. 24th and 25th. The examinations will begin at 9 A. M., and attendance on both days of one month or the other will be required.

For the convenience of applicants outside New England, and through the courtesy of the gentlemen named, entrance examinations will be held on May 30th and 31st, in the following cities:—

New York, N. Y.—In charge of Assistant Professor Davis R. Dewey, of the Faculty of the Massachusetts Institute of Technology, at the Fifth Avenue Hotel. Address until May 29th, Massachusetts Institute of Technology.

Philadelphia, Pa.—In charge of Assistant Professor Dwight Porter, of the Faculty of the Massachusetts Institute of Technology, at the Lafayette Hotel. Address until May 29th, Massachusetts Institute of Technology.

Montreal, P. Q.—In charge of Assistant Professor Alfred E. Burton, of the Faculty of the Massachusetts Institute of Technology, at the Windsor Hotel. Address until May 29th, Massachusetts Institute of Technology.

Chicago, Ill.—In charge of Professor George Howland, Board of Education Rooms, City Hall, corner of Washington and La Salle streets.

St. Louis, Mo.—In charge of Professor E. H. Long, office of the Superintendent of Public Schools, Seventh and Chestnut streets.

Cincinnati, O.—In charge of Dr. E. E. White, office of the Superintendent of Public Schools, Public Library Building, Vine street.

San Francisco, Cal.—In charge of Willis E. Davis, Esq. (S. B., M. I. T.). Address, 211 Drumm street.

Washington, D. C.—In charge of Professor J. H. Blodgett. Address, United States Geological Survey.

St. Paul, Minn.—In charge of George Weitbrecht, Esq., High School Building.

Pittsburgh, Pa.—In charge of Alfred E. Hunt, Esq. (S. B., M. I. T.), at the Rooms of the Engineers' Society of Western Pennsylvania, 713 Penn building, Seventh and Penn streets.

Kansas City, Mo.—In charge of Professor J. M. Greenwood, at the office of the Board of Education.

The requirements for admission as a regular student in the first year class of the School of Industrial Science are as follows: The applicant must have attained the age of 17 years, and must pass a satisfactory examination in Arithmetic, Algebra, Plane Geometry, French (or German), English Language and Literature, History, and Geography.

Applicants for Advanced Standing must pass the entrance examinations, as before given, and present themselves for further examination at 9 A. M. on the Thursday following the second (September) entrance examinations.

Detailed information in regard to requirements for admission and catalogues of the school, can be obtained by addressing James P. Munroe, secretary, Massachusetts Institute of Technology, Boston, Mass.

Cornell University.

A meeting was held April 10th, by the electrical engineering students who made the recent inspection tour. Several papers of interest were read and a discussion of the valuable notes taken upon the trip took place. The following officers were elected at a meeting of the Electrical Engineering Association of Sibley College. Wednesday, April 10th:—Mr. Allen C. Balch, president; Mr. William K. Archbold, vice-president; Mr. Chas. R. Van Trump, secretary and treasurer.

Mr. W. G. D. Crane, E. E. '87, Cornell, has recently become electrician of the Electric Car Company of America, corner 23d street and Washington avenue, Philadelphia, Pa. Mr. William K. Archbold, E. E., '89, Cornell, has arranged to enter the employ of the Westinghouse Electric Co., Pittsburgh, Pa.

The following are some of the Theses, graduates in electrical engineering at Cornell, for the next commencement:—

W. K. Archbold—*Alternating Currents.*
A. C. Balch—*Tests of Insulation.*
H. E. Barrett—*The Thomson-Houston Dynamo.*
H. E. Boskervill—*Design of an Electric Lighting Plant.*
B. H. Blood—*The Third Brush System of Regulating Dynamos.*
C. R. Van Trump—*Design of an Alternating Current Plant.*
C. L. Cornell—*Alternating Currents.*
J. W. Kirkland—*The Electrical Properties of Phosphor Bronze.*
A. Morston—*Study of the Variation of the Modules of Electricity in Structural Steel.*
L. G. Merrit—*Tests on Brush Storage Batteries.*
J. W. Upp—*Design of Electric Lighting Plant.*
L. H. Parter—*Dynamo Regulations by a Third Brush.*
A. Vickers—*Design of a Plant for Alternating Currents.*
F. N. Waterman—*Insulation Tests of Wire.*
F. G. Schlosser—*Design for an Electric Lighting Plant.*

The executors of the estate of the late Captain Ericsson, in accordance with his wishes, will present to Sibley College, Cornell University, a bust of the great inventor as a memorial. The bust will be a duplicate of the one presented to the King of Sweden.

The electrical outfit of Cornell has recently been augmented by the gift of a new Tesla alternating current motor, which will soon receive a thorough test as to its efficiency. A new Thomson electrical balance has also been added to the laboratory.

Mr. H. J. Ryan delivered a very interesting lecture, April 19, to the Electrical Engineering Association of the University. His subject was "Alternating Current Motors."

I. P. Disney, '88, has entered the employ of the Standard Underground Cable Co., of Pittsburgh, Pa.

C. E. Loomis, '88, has recently left the Mather Co. and is now with the Thomson Electric Welding Co., of Lynn, Mass.

P. P. Barton, '86, is with the Westinghouse Electric Co., Pittsburgh, and will soon be attached to their engineering staff.

Mr. L. B. Marks is making a thorough investigation of electric light carbons, from all of the important carbon manufacturers. Valuable data have already been obtained.

Mr. E. P. Roberts, professor of electrical engineering at Cornell, is about to enter the service of the Brush Electric Co., of Cleveland. His departure from Cornell will be a serious loss to the electrical department of Sibley College.

H. N. Brooks, E. E., '88, has entered the employ of an electrical firm in New York city.

Mr. H. J. Ryan delivered an interesting lecture to the Electrical Engineering Association on Friday, April 26. His subject was, "Alternating Current Motors."

Ohio State University.

A course of instruction in electrical engineering has been conducted at Ohio State University, Columbus, for several years with such success, that it has been determined by the University authorities to establish a separate department with a full course, theoretical and practical, leading to a degree for graduates. The course will cover four years, and will be initiated at the beginning of the next college year in September next. A new building, for which plans and estimates have been perfected, will be erected at once for the exclusive accommodation of the electrical engineering department. The outfit will include a fully equipped machine shop and a complete set of dynamos, motors and lamps, exemplifying machines for constant potential, constant current and alternating current, all to be of commercially working capacity. The course of instruction and training will be directed to impart to the students a full measure of practice as well as a thorough grounding in the theoretical principles of electrical engineering. The department has been planned and will be directed by Dr. B. F. Thomas, professor of physics in the University. Dr. Thomas, whose attainments and enthusiastic interest in electrical science and arts are familiar to electricians, has kept in touch with the practical work of electrical engineers no less than with the constant acquisitions of its science, and his supervision of the new department of Ohio State University is a sufficient guarantee of the quality of the work that will be done there.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The Annual Meeting in May.

The annual meeting of the American Institute of Electrical Engineers will be held May 21st and 22d.

The meeting for the election of officers for the ensuing year and for the transaction of other business will be held at the house of the American Society of Civil Engineers, 127 East 23d street, New York, Tuesday evening, May 21, at 8 P. M.

The morning session of the general meeting for the reading and discussion of professional papers will be held at the same place, beginning at 10 A. M., May 22. A collation will be served at 1 P. M., and the meeting will then reassemble for the afternoon session at the College of the City of New York, No. 17 Lexington avenue, where suitable electrical apparatus will be provided for experiments connected with such papers as require them.

The following papers will be read by the authors: "Modern Views as to the Nature of the Electric Current," with experiments, by Professor H. A. Rowland; "The Inherent Defects of Lead Storage Batteries," by Dr. Louis Duncan; "The Regulation of

Dynamos and Motors," by Dr. Schuyler S. Wheeler; "The Measurement of Telephonic Currents," by Professor Chas. R. Cross; "A Series of Tests on the Life and Efficiency of Incandescent Lamps," by W. H. Peirce, of the Chicago, Burlington & Quincy R. R.; "Some Results with Storage Batteries in Train Lighting, by Alexander S. Brown," of the Pennsylvania R. R.

Also, Professor Elihu Thomson is expected to read a paper treating upon "Magnetism and its Relation to Induced Electromotive Force and Current." Professor Thomson's design is to select typical examples and unfamiliar cases of the relation of a magnetic field to induction in illustration of his general theme.

THE ELECTRIC LIGHT AT THE PARIS EXHIBITION.

M. Hippolyte Fontaine has read a paper on this subject before the International Society of Electricians in Paris, from which we extract the following particulars. The total cost of the exhibition to the French government and town of Paris is estimated at about £2,000,000. There are, in round numbers, 50,000 exhibitors, of whom each will spend on an average £120, representing an additional outlay of £6,000,000, so that the whole cost of the exhibition may be roughly estimated at £8,000,000. The total earning capacity of exhibitions depends, amongst other things, upon the number of hours during which the public has access. If no artificial lighting were used, the total number of hours would amount to 1,620; but by the adoption of the electric light, this number has been increased to 2,520, reducing the cost of the exhibition per hour from nearly £5,000 to a little over £3,000. Although this is a substantial gain wholly due to electric lighting, the administration have not cared to erect the necessary plant at their own cost, or to pay for the light at a fixed rate, as they do with steam, water, gas, &c.; but they have agreed to hand over to the purveyor of the light one-half the entrance money received from visitors in the evening, and which is fixed at two francs on week days and one franc on Sundays. The electric lighting plant has been provided and will be worked by the Electric Lighting Syndicate, which has been formed with a view to make the lighting an international undertaking. The lighting has been divided between a number of firms and systems, and this will afford an excellent opportunity for comparisons. The machinery hall, which has a floor space of 77,000 square meters (or about 19 English acres) and a volume of 2,000,000 cubic meters, will be lighted by arc lamps of various sizes. The largest lamps are arranged in four groups of 12, close under the ridge of the roof. These will be 60 ampere lamps, and will burn 25mm. carbons. Eighty-six 25 ampere lamps are distributed in five longitudinal rows, and suspended about 15m. from the floor. The side galleries of the machinery hall and the stands adjacent to them will be lighted by 276 eight ampere arc lamps suspended 5m. from the floor. The lighting is being undertaken by the following contractors :—

For the 25 Ampere Lamps.

Crompton & Co	24
Maison Ducommun	20
Sautter, Lemmonier & Co	12
Jaspar	11
Société Belge	6
Borssat	5
Société Française de Materiel Agricole	4
Henrion	4

For the 8 Ampere Arc Lamps.

Crompton & Co	79
Maison Ducommun	76
Sautter, Lemmonier & Co	80
Alioth & Co	30
Oerlikon Works	25
Société Française de Materiel Agricole	8
Société Belge	8
Henrion	8
Jaspar	7
Popp & Co	5

In addition to the arc lamps, there will be various installations of glow lamps, contracted for by the following firms :—

Woodhouse & Rawson	8 of 200 c. p.
Garnot	10 of 250 c. p.
Jarriant	369 of 8 c. p.
Crompton	160 of 8 c. p.

The annex devoted to railway exhibits, which comprises nearly 6,000 square meters of surface, is to be lighted by five 25 ampere and thirty 8 ampere arc lamps by M. Borssat, whilst the large central dome will be lighted by the Société Gramme by 48 glow lamps of 500 c. p. Besides the spaces here mentioned, the various other annexes and courts will receive separate installations, but want of space precludes our giving a full list. In the open spaces the lighting will principally be effected by continuous current arc lamps and Jablochkoff candles, and the work is divided between the Paris Edison company, the Rothschild-Marcel-Deprez combination, the Maison Ducommun, and the Société l'Eclairage Electrique, who work the Jablochkoff system. The large fountain which is being erected by Messrs. Galloway, of Manchester, in conjunction with the administration, will be lighted by the Gramme company, of Paris, with 48 arc lamps, requiring about 250 h. p. There will, however, be a second fountain erected by Messrs. Galloway, who are for this purpose utilizing the plant which was in use at the Manchester exhibition, and this fountain will be lighted by eighteen 60 ampere arc lamps. M. Fontaine gives the following table, showing the total amount of light which will be nightly employed :—

Lamps employed.	Units of 1,000 candles.
51 arcs of 60 amperes	510.0
100 " 25 "	350.0
10 " 15 "	20.0
726 " 8 "	726.0
97 Jablochkoff candles	38.8
16 sun lamps	16.0
72 glow lamps of 500 candles	36.0
10 " " 250 "	2.5
3500 " " 10 "	35.0
6500 " " 5 "	32.5
Total	1766.8

In this table we have for simplicity assumed that one carcel is represented by 10 standard candles. Correctly speaking, it is 9.6 candles, and the total amount of light will thus be reduced to about 1,700,000 candles. There will thus be employed in the lighting of the exhibition a candle-power close upon 1¾ millions.—*Industries.*

TELEGRAPH EXTENSION IN FRANCE.

The French Telegraph Administration proposes to join Paris and the suburbs by an electric network, which is to be more important and developed. The first telegraph lines to be constructed with that object in view will be those from the Porte of Courcelles to Lavallois-Perret and from the Porte of Maillot to Puteaux (Quai National). This is to be carried out without the usual legal formalities, and already details of the lines in question have been addressed to the municipalities interested.

ELECTRICAL EXHIBITION AT ST. JOHN, N. B.

The Board of Trade of St. John, N. B., announces that an exhibition of electrical appliances will be held in that city, opening on the first of July next and continuing 10 days or more. The exhibition is planned in connection with the carnival celebrating the union of the cities of St. John and Portland, and the opening of their connection with the Canadian Pacific Railway. Exhibits from the United States are cordially invited by the St. John Board of Trade. Special arrangements are undertaken for the entertainment of representatives of the technical and general press.

NEWSPAPER ELECTRICITY.

The competition between alternating and continuous currents may be called a race between the alternating current motor and the accumulator.

Three hundred miles an hour is the proposed speed for the electric postal railroad of the future.

The sparking of a transformer-wound motor is claimed to be altogether insignificant.—*N. Y. Times.*

CLUB NOTES.

The Electric Club, New York.

At the annual meeting of the Electric Club, April 18th, the postponed resolution amending the by-laws by increasing the dues and membership fee was taken up, and the following increase unanimously voted :—

Commencing May 1st, 1889, resident members will pay an initiation fee of $50; annual dues of $50.

Non-resident members beginning with the same date shall pay an initiation fee of $25; annual dues of $30.

The following-named gentlemen were elected officers of the club for the year beginning May 1st, 1889 :—

President—E. T. Gilliland.

Vice-Presidents—O. E. Madden, Theo. N. Vail, E. N. Dickerson, H. C. Davis.

Secretary—Chas. W. Price.

Treasurer—Willard L. Candee.

Board of Managers—M. W. Goodyear, John A. Seely, H. L. Storke, W. H. Johnstone, A. H. Patterson, Geo. B. Coggeshall, Cyrus O. Baker, Jr., J. C. Tomlinson, Henry A. Reed, J. W. Handren, H. D. Stanley, C. H. Barney and C. E. Stump.

Committee on Membership—Henry Hine, Lieutenant F. W. Toppan, U. S. N., Geo. Worthington, Geo. T. Manson and Henry D. Lyman.

Chicago Electric Club.

The annual meeting of the Chicago Electric Club was held April 18. The following officers were elected :—President, S. A. Barton; vice-president, 1st, H. Ward Leonard; 2d, F. B. Badt;

3d, Alex. Kempt; 4th, D. P. Perry; secretary, W. A. Kreidler; treasurer, F. S. Terry; managers, B. E. Sunny, F. E. Degenhardt, M. A. Knapp, E. Baggott, H. A. Glasier, William Zimmerman, W. M. Lenhart, George B. Bailey, C. K. Giles, E. A. Sperry. Membership committee, C. C. Haskins, W. H. McKinlock, George W. Whitefield, F. W. Parker, J. H. Shay. It was voted to assess each member $10 to aid in furnishing the new club rooms. It was stated that 15 members would contribute $100 each for this purpose.

Harvard Electric Club.

The Harvard Electric Club elected officers as follows, at a meeting held April 17:—President, J. Hale, L. S. S.; 1st vice-president, F. S. Duncan, '90; 2d vice-president, B. H. Rounsaville, L. S. S.; secretary, L. K. Perot, L. S. S.; treasurer, A. N. Baron, '91; librarian, G. T. Page, '92. At the same meeting five new members were admitted, and letters of acceptance of honorary membership were read from Professors John Trowbridge, B. O. Pierce, E. H. Hall, and Dr. Harold Whiting.

ELECTRIC LIGHT AND POWER.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION has removed its head-quarters and office of the secretary from Madison square to 18 Cortlandt street, New York, room 512. The new location will give the secretary, Mr. Allan V. Garratt, more convenient access to the electric light companies, most of which have their offices down-town.

THE SPERRY ELECTRIC CO., of Chicago, the owners of the patents of Mr. Elmer A. Sperry, are drawing attention to the comprehensive arc lighting system of Mr. Sperry, and they have the best wishes of the electrical trade. A pamphlet recently issued embodies in compact and striking form the technical and practical claims made for their apparatus, and presents many features of interest. The list of installations given is extensive, and embraces a number of large office buildings and hotels, as well as central stations.

THE WESTINGHOUSE ELECTRIC CO., during the first half of the present month received orders for alternating current outfit aggregating a capacity of 10,750 lights. These included initial orders from St. Joseph, Mo., 3,000 lights; Newburgh, N. Y., 1,500 lights; Decatur, Ills., 750 lights; Oxford, O., 1,000 lights and a 50-light Waterhouse arc outfit; Wyoming, O., 750 lights; New York, the Safety Light, Heat and Power Co., 3,000 lights. Increase of existing plants,—Washington, Pa., 750 lights. A year ago 79 central stations were using or erecting Westinghouse alternating plants. On the 15th inst. the number had reached 160, with an aggregate capacity of 300,000 16-c. p. lamps.

During the latter half of April the Westinghouse company received orders for alternating current outfits as follows: Jonesborough, Ark., 750 lights; Westerly, R. I., 500 lights; Newark, N. J., 750 lights; Ottawa, Kas., 750 lights; Ashland, N. H., 500 lights; Minneapolis, Minn., 600 lights (increase); Auburn, Me., 750 lights; Traverse City, Mich., 500 lights. The total of orders for the month of April aggregates 15,850 16-c. p. lamps capacity. Total for four months to April 30, 74,000 16 c. p. lamps capacity. About one-third of the central station companies using the Westinghouse system have increased their capacity since starting, in most cases at least doubling their original outfit.

THE THOMSON-HOUSTON ELECTRIC CO. report the following sales of arc and incandescent lamps:—

Adams, Mass., 45 arc; Sanford Woolen Mills, Medway, Mass., 100 inc.; Monroe County Insane Asylum, Rochester, N. Y., 600 inc.; Saxon Woolen Mills, Franklin, Mass., 200 inc.; New England company, Bath, Me., 300 inc.; Buffalo, N. Y., 190 arc.; Lowell, Mass., 1,000 alt.; Leominster, Mass., 50 arc, 600 alt.; Leicester, Mass., 600 alt.; Hudson, N. Y., 45 arc; Portland, Me., 45 arc; Manchester, N. H., 100 arc; Revere, Mass., 600 alt.; Findlay, O., 1,000 alt.; Woonsocket, R. I., 1,000 alt.; Pitman, Mass., 500 alt., 50 arc; Rockland, Me., 30 arc; Savannah, Ga., 250 arc; Malden, Mass., 500 alt.; Upper Sandusky, O., 60 arc; Columbus, Ga., 1,000 alt., 100 arc; Thomasville, Ga, 50 arc; Perry Paine building, Cleveland, O., 1,000 inc.; Falls City Jean and Woolen Mill, Louisville, Ky., 200 inc.; Stearn & Silverman, Wheeling, W. Va., 20 arc; Mowry building, Syracuse, N. Y., 200 inc.; New Haven, Conn., 45 arc; Washington Court House, O., 50 arc; Cambridge, Mass., 1,000 alt.; Hudson River State Hospital, Poughkeepsie, N. Y., 800 inc.; Bedford, Pa., 50 arc, 600 alt.; Stamford, Conn., 1,500 alt.; Fernandina, Fla., 50 arc; New Decatur, Ala., 50 arc; Chester, Pa., 30 arc; H. W. Smith, Bangor, Me., 50 inc.; T. J. Stewart, Milo, Me., 50 inc.; Riverside and Oswego Mills, Providence, R. I., 400 inc.; Morse & Whyte, Cambridge, Mass., 200 inc.; Jewell Milling Co., Brooklyn, N. Y., 200 inc.; James Walker & Co., Basin Mill, Me., 50 inc.; Fort Paine Coal and Iron Co., Fort Paine, Ala., 400 inc.; J. B. Mason, Providence, R. I., 50 inc.

THE THOMSON-HOUSTON ELECTRIC CO. report the following sales of stationary motors:—

Walker and Pratt Manufacturing Co., Boston, 7.5 h. p.; J. H. Kelly, Providence, R. I., 1 h. p.; Georgia Electric Light Co., Atlanta, Ga., 10 h. p.; Master Builders' Association, Boston, 10 h. p.; A. Harris, Providence, 1 h. p.; Bonschur and Holmes, Philadelphia, 1.5 h. p.; H. W. Ladd, Providence, 3 h. p.; W. Shedley, Providence, 1.5 h. p.; J. J. Hillman, Boston, 10 h. p.; Garfield and Proctor Coal Co., Boston, 15 h. p.; Cambridge Shirt Co., Cambridgeport, Mass., 1 h. p.; A. C. Manchester, Providence, 1.5 h. p.; New Bedford Gas Co., New Bedford, Mass, 1.5 h. p.; C. F. Heptonstall, Providence, 3 h. p.; B. F. Haley, Dover, N. H., 1 h. p.; John M. Sweeney, Wheeling, W. Va., 1.5 h. p.; E. L. P. Martin, Providence, 3 h. p.; T. C. Entwistle, Lowell, Mass., 5 h. p.; Minot estate, 39 Court street, Boston., 15 h. p.; Whittier Machine Co., Boston, two motors for elevators, 20 h. p.; Thomson-Houston Electric Light and Power Co., Buffalo, N. Y., 5 h. p.; Wales Manufacturing Co., Syracuse, N. Y., 10 h. p.; St. Catharines Electric Railway Co., St. Catharines, Ont., 5 h. p.

THE growth of the electric motor industry has resulted in bringing out a number of ingenious designs and constructions aiming to secure the maximum efficiency and regulation under all conditions, and the modern motor shows a remarkable advance towards becoming a model machine from the machinist's as well as the electrician's point of view.

The latest claimant for the attention of the trade is the Connecticut Motor Co., of Hartford, Conn., who claim to produce a motor embodying the result of an extensive study and experience in this field. They manufacture shunt wound motors of from one-half to 10 h. p. for constant potential circuits, and announce that motors for constant current lines will shortly follow. The makers have sought to secure harmonious relations and proportions in the electrical and mechanical details of their motor, and claim to have produced a machine that is durable and non-sparking, and of high efficiency under changes of load.

Foreign.

Austria.—The arrangements for the electrical lighting of the Parliament building in Vienna, have lately been completed. The whole hall is now lighted by incandescent lamps. Between the skylight and the roof proper, are 25 large incandescent lamps of 400 c. p. each, which throw a bright yellow-white light over the hall, making the place appear nearly double so bright as was formerly the case by gas lighting. In the second gallery, in addition to these, are 20 candelabra, each with three lamps of 16 c. p. each. The machines and accumulators which furnish the current represent 120 h. p. The insulating of the wires has been carried out in the most careful manner. The principal cable runs through one of the many ventilating pipes over the skylight, so that the expensive decorations on the walls remain uninjured; while for the lamps in the gallery, the wires are carried through the gas pipes which were already there.

France.—The Parisian technical press, it appears, complains that the action of the city government renders impossible the use of electricity as a means of transmission of power, very much as the English electricians accused the electric lighting act of retarding the progress of the electric light in England. The whole question arises from considerations regarding a practicable scheme for the conductors. Of course, special lines or routes for every different purpose are not to be thought of. Especial canals for accommodating pneumatic tubes, pipes and conductors for transmission of power and for lighting, which would be a costly undertaking, appear at last to be not only practicable but also necessary. Something very nearly approaching this, Paris already has in its sewers. In some of these, pipes and conductors have already been successfully set up, but these seem not to have been seen by the council. Still another proposition is made which, in spite of its problematic character, the press heartily supports.

It is proposed that the gas, which is now used for lighting and warming, be used for driving gas motors, and these, in various stations throughout the city be made to drive dynamo machines; the current from these dynamos to be—with comparatively small cost it is said—distributed over the city by means of conductors running in the far reaching sewers with which Paris is so plentifully provided.

Germany.—THE council of Hamburg, has decided to request the senate to lower the price of gas for motor running to 15 pfennig (3.65 cents) per cubic meter. There is now a uniform gas price of 18 pfennig (4.37 cents) per cubic meter, without regard to the use for which the gas is intended.

AT Berlin, the stock company for the manufacture of the "Seel" incandescent lamps, has lately made its statement to the Berlin exchange, and with this opportunity has made public its prospects. The call for incandescent lamps increases from day to day, and the company is compelled to make the most strenuous efforts, even having to run nights, in order to supply the demand.

Their report for 1888, shows the production to be 800 lamps per day. After the completion of the two factories now building—to cost 110,000 marks ($28,000)—the capacity of the plant will be increased to 2,300 lamps per day. The probability of selling all the lamps the factory can furnish, is pretty well assured, since already

contracts for the delivery of 195,000 lamps are closed, against about 100,000 for the whole of last year.

From another source we learn that the patents belonging to this company have been attacked—the principal claimant being the Allgemein Electricitäts Gesellschaft.

PERSONAL MENTION.

MR. C. J. KINTNER has associated himself with Dr. Leonard Paget, of New York, under the firm name of Paget & Kintner, for the purpose of acting as chemical, mechanical and electrical experts, and electrical engineers. Dr. Paget is well known both here and in Europe, as an electrician and chemist, and was for several years, assistant professor of applied electricity in Kings College, England, and associated with Professor Sir Charles Wheatstone. He was also consulting engineer of the Anglo-American Brush Co., and Messrs. Siemens Bros., of London. He is the inventor of the Macraeon storage battery. Messrs. Paget & Kintner purpose acting as electrical and chemical experts in both the Patent Office and courts, and in the rendering of opinions upon all matters of such nature for investors or others. Their office will be at 45 Broadway, where Mr. Kintner has been located for some time.

MR. W. D. SARGENT, vice-president of the National Telephone Association, and general manager of the New York and New Jersey Telephone Co., who has been appointed to take charge of the American telephone exhibit at the Paris Exposition, sailed for his post, on the steamship "La Gascogne," Saturday, April 13. In anticipation of his departure, some 30 of his associates in the telephone field united in giving him a complimentary dinner at the Electric Club, of New York, on the evening of the 11th inst., and this "send off" turned out to be one of the pleasantest affairs of the kind in the memory of those present. Mr. Sargent's numerous friends of the electric fraternity throughout the country who were unable to be present will unite in wishing him a pleasant sojourn across the water, and in hoping that he may safely return—according to his present intention—in time to be present at the Association meeting next September.

MR. GEO. W. BRECK, mechanical draughtsman, who has for some time made a specialty of electrical patent drawings, removed April 20th from 160 Fulton street to 5 Dey street, one door west of Broadway, room 17.

MANUFACTURING AND TRADE NOTES.

THE WILLIAMS ENGINE WORKS are to have a Shaw electric traveling crane for their new shops at Beloit. It will have a span of 40 feet, and be proportioned for a working load of 15 tons, but is to sustain a test load 50 per cent. in excess of this, or 22½ tons without injury. It is being built by Edward P. Allis & Co., of Milwaukee, who have had one of these cranes of 25 tons capacity in successful operation in their foundry for several months.

THE TUCKER ELECTRIC CONSTRUCTION CO., have removed to their new offices, Nos. 14, 16, 18, 20 Whitehall street, opposite the Produce Exchange.

THE ELEKTRON MANUFACTURING CO., on May 1, move their office from New York to their factory in Brooklyn, being fully convinced that this will facilitate their business. Their location in Brooklyn, corner of Jay and Plymouth streets, is only five minutes walk from the bridge, and is, therefore, easily accessible from New York.

The company report that purchasers have been more prompt to appreciate the merits of the Perret motors and dynamos than they expected, and orders have come in of late faster than they could be filled. They are making a considerable increase in their manufacturing facilities, and expect soon to catch up with orders.

THE ANSONIA BRASS AND COPPER CO. issue a circular setting forth the merits of "Tobin bronze" an alloy which is claimed to be remarkable for its high elastic limit, tensile strength, toughness and uniform texture. It is said to be stronger than ordinary mild steel in rods or plates, and finds use in the construction of machines of many kinds. It has already been employed in the construction of phonographs, electric traction machinery, steam pumps, and other machinery.

MESSRS. FLEMING AND KIMBALL, 17 Dey street, New York, have taken the general agency for the Connecticut Motor Co., of Hartford, Conn. This firm also represents in New York the Harrisburg Car Manufacturing Co., makers of automatic engines for electric lighting stations.

THE NATIONAL GALVANIC BATTERY CO., 18 Cortlandt street, New York, are in the market with a new porous cup for which they claim points of merit. The cup is perforated so that no soaking is required, and platinum contacts protect the binding posts and lead from corrosion.

THE CONTINENTAL DYNAMO CO., of 42 Exchange place, New York, are making a dynamo which possesses several interesting features. The field is of the iron-clad type and the mechanical work on the machines we have seen is of the best description.

A. L. BOGART, 22 Union square, issues a new catalogue and price list of electric gas lighting apparatus and electrical supplies, under date of April 1889. Mr. Bogart was one of the early workers in the field of electric gas lighting, and after many years of experience and increasing business offers, in his catalogue, a large variety of apparatus and appliances, adapted to different conditions and requirements, and at a reduced scale of prices.

NEW INCORPORATIONS.

Concord Electric Co., Concord, Mass., T. T. Robins and others. Capital, $20,000.

Steubenville Gas and Electric Co., Steubenville, O. Capital, $300,000.

Turtle Creek Valley Electric Light Co., Harrisburg, Pa. Capital, $50,000.

Provincetown Electric Co., Provincetown, Mass., J. D. Hillard and others. Capital, $15,000.

Advance Illuminating Co., Newark, N. J., Henry C. Rommell and others. Capital, $100,000.

Phoenix Incandescent Lamp Co., Chicago, Ills., A. F. Oppermann and others. Capital, $100,000.

Riggs Electric Traveling Danger Signal Co., St. Paul, Minn., Joseph W. Riggs and others. Capital, $3,000,000.

American Electric Meter Co., Chicago, Ills., John Marder and others. Capital, $200,000.

Sperry Electric Mining Machine Co., Chicago, Ills., Albert L. Sweet and others. Capital, $100,000.

Union Electric Car Co., Portland, Me., Lewis M. Child and others. Capital, $1,000,000.

Moorestown Electric Light, Heat and Power Co., Moorestown, N. J. Capital, $50,000.

Bryan Electric Co., Bryan, Ohio. Capital, $30,000.

Neponset Electric Co., Boston Mass., J. B. Smith and others. Capital, $50,000.

Acme Electric Co., St. Paul, Minn., Chas. F. Diether and others. Capital, $200,000.

San Marcos Electric Light and Power Co., San Marcos, Texas, John Cook and others. Capital, $10,000.

Union Electric Light Co., Franklin, Mass., A. H. Morse and others. Capital, $20,000.

Madison Light and Power Co., Madison, Dak., W. H. Jones and others. Capital, $25,000.

Lebanon Electric Light Co., Lebanon, Ky., John Rubel and others. Capital, $15,000.

Saginaw Electric Light and Power Co., Saginaw, Mich., A. McIntyre and others. Capital, $25,000.

National Electric Traction Co., Detroit, Mich., W. A. Jackson and others. Capital, $100,000.

Keelyn Electric Co., Milwaukee, Wis., James Keelyn and others. Capital, $1,000.

Livingston Electric Light Co., Livingston, Mont., J. Orschel and others. Capital, $25,000.

Harrodsburg Electric Light and Power Co., Harrodsburg, Ky., G. Bohon and others. Capital, $25,000.

Green Bay and Fort Howard Electric Railway and Power Co., Chicago, Ills., H. Ward Leonard and others. Capital, $100,000.

Belleville Electric Light and Power Co., Belleville, Ills., E. Abend and others. Capital, $25,000.

South End Electric Light Co., Chicago, Ills., G. Falkenburg and others. Capital, $30,000.

Notes.

THE following report of the Cambridge division of the West End Street Railway, Boston—Thomson-Houston electric road—for the month of April has just been received :—

Average number of motor cars in daily service,	8
Round trips of motor cars,	2,720
Time in service, motor cars,	3,232 hours.
Mileage of motor cars,	17,680 miles.
Round trips, one tow car,	2,720
Round trips, two tow cars,	226
Time in service, towed cars,	3,500 hours 30 minutes.
Mileage of towed cars,	19,149 miles.
Total car round trips,	5,666
Total car mileage,	36,829 miles.

Of the above round trips but seven were lost.

This road has a previous record of but nine trips lost out of 1,179.

THE ELECTRICAL ACCUMULATOR Co. proposes to push on in the field of electric traction, and announces its readiness to equip street railways on the two following methods :—

First. The placing of motors, gearing and accumulators on ordinary cars, say 16 or 18 feet long. *Second.* The placing of accumulators on separative or locomotive cars, about 9 feet long, which can be used also as smoking cars, affording seats for about 10 persons.

The locomotive or smoking car need not be built with a regular body, as it requires only truck, platform, seats, and a weather hood, and no windows, upholstering or expensive finish. They will cost from $200 upwards, it is estimated, ready for the motors and batteries.

Their motors are known as the "Edco," and, as now made, are rated at 10 h. p. each, but are capable for brief periods of time of exerting considerably greater power. Each ordinary street car is usually provided with two motors, which are built by the Electro Dynamic Co., of Philadelphia, one of the oldest and most experienced electric motor companies.

A car battery when fully charged is claimed to be capable of propelling an ordinary car loaded with 50 passengers, over a level road, at the rate of 9 or 10 miles an hour, for about 6 hours, allowing for the average car stops and lay-offs at the terminals. The car would therefore require one change of batteries for a day's run of 12 hours. The batteries supply electric light for inside lamps and head lights, and power for signal bells and alarm gongs.

An accumulator car can ascend steeper grades, and can go at a faster rate of speed, either on grades or on a level road, than is possible with horses, but always, of course, with a correspondingly greater expenditure of energy. In case of a single excessive grade on an otherwise level road it may be advisable on the score of economy not to provide power for each car sufficient for surmounting such grade, but to use an auxiliary motor car, or tow horse, as is now customary. Accumulators, like horses, are for brief periods of time, capable of doing many times their safe or normal amount of work ; but also, like horses, any excessive amount of work which they are called upon to do, can only be done at the cost of shortening their life. The Accumulator company furnish the following estimates :—

The cost of a 16-foot car equipped with motors, necessary gearing, and two sets of batteries, will be from $4,500 to $5,000,

according to the character of upholstery and other finish; without accumulators the cost will be about $3,000. The cost of a locomotive smoking car, equipped with batteries, will be about $1,800.

The company is of opinion that it will not be economical to provide a steam and generating plant for less than 10 cars, and say that for this 75 h. p. will be sufficient. Where the locomotive car plan is adopted, 10 h. p. for each passenger car with its tender should be allowed, but in such case the car mileage is proportionately increased.

The uncertainty of estimates on the depreciation of accumulator plants, so far as concerns the batteries themselves, has been perhaps the chief obstacle to a more general introduction of them than has taken place thus far. In respect to this feature, the Electrical Accumulator Co. offers to insure (or renew) the worn out battery plates for an annual charge of 25 per cent. of the list price of the accumulators. This charge is considerably in excess of what they believe will be the actual cost of renewal, but they feel obliged to charge for the risk of accidents over which they have no control, and of carelessness on the part of employés other than their own. Here then is a maximum figure for the item of battery depreciation in an estimate of operating expenses.

One of the cars equipped with the Electrical Accumulator Co.'s batteries and the "Edco" motor, constructed by the Electro Dynamic Co., of Philadelphia, made a very successful trip, April 10th, over the Darby branch of the Traction line in Philadelphia. This particular road was selected for a trial trip owing to the long, steep grades and sharp curves with which it abounds. Grades and curves were readily taken, and a remarkable uniformity of speed was maintained over them.

On a particularly bad piece of track, a sharp curve on a hillside, the car left the track, but by the application of a little more power from the batteries the motors backed the car into place on the rails, and the trip was resumed with but little delay, and without blocking the road.

THE SPRAGUE ELECTRIC RAILWAY AND MOTOR Co. has, during the past month, made contracts to equip two more railways in St. Joseph, Mo. That city was among the earliest to adopt electricity upon its street railroads, and on its Union Passenger Railway demonstrated the manifold advantages of electric power. After that road had been running some time, another St. Joseph railway, the Wyatt Park line, installed a complete equipment of electric cars, which have now been running about six months. There only remained two other railways in St. Joseph, and these two railway companies, through their presidents, have now contracted with the Sprague Electric Railway and Motor Co., which furnished the equipment for the other two St. Joseph roads, for the entire equipments of their lines. These orders amount to 20 cars and over 10 miles of track. Since the Union Passenger and the Wyatt Park lines have been in operation, they have been so extensively patronized that each of these companies have ordered additional equipment of five and nine cars respectively. These orders now make 44 electric cars which are now in operation or have been ordered for the City of St. Joseph alone, with nearly 25 miles of track.

In addition to this remarkable showing in electric railways, the City of St. Joseph has shown uncommon enterprise in installing stationary motors, very many of which are in use for all kinds of industry, and their number is very rapidly increasing.

THE THOMSON-HOUSTON ELECTRIC Co. have lately closed the following street railway contracts:—

Lynn and Boston Railroad Co., Nahant line. This line has 4,869 feet of track, 2 turnouts, maximum gradient of four per cent., and will extend from Central square, Lynn, to the Nahant House, Nahant. One car will be put in operation at first, the power for which will be obtained from the station of the Lynn Electric Light Co.

Newburyport and Amesbury Horse Railway Co., Newburyport, Mass. This line is about 6 miles in length and will operate 2 cars. It is made up almost entirely of curves and grades, the maximum grade being ten per cent. The current will be taken from the Newburyport Electric Light Co. and the Amesbury Electric Light Co.

The Newton circuit line, Newton, Mass. This line will operate 10 cars and is 8 miles in length, maximum gradient of five per cent. It will run from Newton to Watertown on the West End track, and on new track from Watertown to West Newton and Newtonville.

The Plymouth and Kingston Railway Co., Plymouth, Mass. This line is 4 miles in length and will operate 3 cars. The maximum gradient is six per cent. The line will run from Chiltonville through Plymouth to Kingston. On nearly all of the line the bracket method of suspension will be used. The track is nearly all laid.
